Dr. C. F. Theisen—In closing the discussion I would say that I am sorry most of the gentlemen seem to have missed one of the main points in my paper. They have been discussing general laryngeal edema and s [illegible] which is often merely part of a general [illegible] fauces. These are not identical conditions with the one I have attempted to describe. The point I intended to bring out in my paper was that the cases I have reported were those of acute primary epiglottitis or angina epiglottidea anterior, with no involvement of the pharynx; that in secondary epiglottitis there is, as a rule, a general acute angina. Dr. Mackenzie said in his discussion that the "condition had been known almost for all time." This may be true to a certain extent, although, of course, an absolutely accurate diagnosis could not be made in these cases before the discovery of the laryngoscope. I did not make any particular claim for its rarity, although I will say again that primary epiglottitis is rare. A good many of the cases reported by the earlier French, German and English writers were probably cases of secondary epiglottitis, or of edematous laryngitis. Dr. Mackenzie also spoke of Washington's case. I did not mention it because it does not strictly belong in a paper with this title, and then, too, it has been a disputed point what Washington died of. At the time of his death the cause was given as quinsy, and this is mentioned by Henry Cabot Lodge in "American Statesmen." The consensus of opinion seems to be that his death was due to acute edematous laryngitis. This is mentioned by Marsh in his article, and also by Lodge.

ATHREPSIA INFANTUM—MARASMUS, OR WASTING DISEASE—ATROPHY—MALASSIMILATION OF FOOD.

ITS CAUSE AND TREATMENT—PROPER INFANT-FEEDING.*

LOUIS FISCHER, M.D.
NEW YORK CITY.

If infants, when a few months old, suffer with vomiting or diarrhea, and this condition is allowed to become chronic, then colic and flatulence associated with constipation supervene, and result in a gastrointestinal catarrh. Neglect of this condition means the development of the condition known as athrepsia. The infant does not thrive, commences to waste, and unless we realize the condition and give the baby proper treatment, such a child will die of exhaustion from inanition. When these cases linger for months they develop rhachitis. Recovery without treatment is impossible. Parrott was the first to define this disease, and classified it into three stages:

1. The infant suffers from a simple diarrhea or looseness of the bowels. The stools, instead of being bright yellow and homogeneous, are liquid, curdy, often of a green color, and contain an excessive quantity of mucus. The abdomen is distended with gas and remains constantly in this condition; the tongue is coated and the patches of a stomatitis appear in the mouth. The infant is restless, constantly whining, and will not sleep at night. The milk being retained, curdles; the tissues become flabby, and wasting commences.

2. The symptoms are intensified and the characteristic wasting becomes manifest. The stools for the most part are loose and frequent, and consist of undigested food; they are often pale and putty-like, with a peculiar odor. At other times they are of a dark brown, from the presence of altered bile. The infant is most voracious, liquid food does not seem to satisfy it, and by the mistaken kindness of its friends it is fed with some thick food, like soft bread, a diet which has the great advantage in their eyes of keeping it quiet for a longer time than liquid food or diluted milk. At times it can hardly be made to sleep, or only dozes for a short time, unless under the influence of a soothing-syrup applied by its nurse. The mouth becomes the seat of a parasitic stomatitis; the skin is harsh and dry; small boils or a lichenous rash makes its appearance. The buttocks and genitals are raw and excoriated. Its temperature is below normal; the feet and hands are congested, the face has a pallid, earthy tint, and a sickly lactic-acid smell is given out from the body, especially the abdomen. The wasting is extreme, the face being shriveled, the skin wrinkled and hanging in folds about the thighs and arms.

3. The third stage brings the child into a moribund state. It is too feeble to cry, becomes heavy and drowsy, taking little notice of anything. Death then ensues, probably preceded by a muscular twitching, strabismus or general [illegible]

Henoch does not like the term "athrepsia," introduced by Parrott, but prefers "atrophy." The first symptom that this author noticed is that the child's weight does not increase, and hence he emphasizes the importance of frequently weighing children. He regards the weight taken once a week as sufficient, so that it can be a determining factor as to the progress made by an infant. Henoch says that at the end of the first month the weight is increased one-third, at the end of the fifth month it is double, and at the end of the twelfth month it should be three times the weight at birth. Weaning, dentition and all other pathological conditions interfere with a proper increase in weight.

By far the greatest number of cases of athrepsia are found in bottle-fed children. There are, however, a great many cases to be seen among breast-fed children. We can then be positive that the breast milk is lacking in some of its chemical constituents, and frequently we find that it is the proteids that are deficient in quantity. If, therefore, we meet with a case of athrepsia in a breast-fed child the thing to do is to have a chemical examination made of the breast milk. If the latter is found deficient in quality, then we must withdraw it.

A great many children will be found to thrive at once after having been removed from the breasts and changed to some artificial mode of feeding, whereas the reverse is also true. If, therefore, we wish to do away with its own mother's milk, for some positive reason, it is advisable to secure a wet nurse having a child as near the age of the one she is to suckle as possible. The hereditary history of a nurse is of great importance, as is also the quantity and quality of her milk, which should be thoroughly examined before she is given this foster child.

The treatment of this disease is one which resolves itself into removing the cause, and if bad hygienic surroundings, as impure air, crowded apartments and improper diet are the cause, then these must be remedied at once. Medication amounts to nothing in the treatment of this disease.

With hand-fed or bottle-fed children we can easily regulate the condition of their bowels and also easily regulate the quality and quantity of the food given them. The blandest and least irritating food must be selected, while frequent weighing of the infants should be resorted to in order to ascertain the progress that is being made.

Where there is much diarrhea, milk must be used sparingly or altogether omitted for a while, as the hard curds formed in the stomach are beyond the weak digestive powers of the weakened stomach and intestines. Small quantities of whey and barley-water, white of egg and barley-water, or the juice of a rare chop or steak may be given at short intervals during the day and night.

---

*Presented to the Section on Diseases of Children, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

As soon as the child improves in respect to the diarrhea, milk in some form may be allowed. Peptonized milk is often of much value in these diseases when made by mixing three ounces of cold milk, adding two teaspoonfuls of cream, with one-half of a peptonizing powder to sweeten it, and giving it to the infant after it has stood for fifteen minutes.

The cream mixtures are often of much service, such as one ounce of cream, three ounces barley-water, one teaspoonful of sugar. Every care must be taken that the feeding-bottle is clean, and the food prepared with the most scrupulous neatness.

The great difference between cow's milk and human milk is the fact that human milk is persistently alkaline, whereas cow's milk is usually acid; that there is more nitrogenous material in cow's milk; that there is a much smaller percentage of milk-sugar in cow's milk, and finally, that the nitrogenous constituents of the milk of the cow are affected by rennet in a manner different from those of mother's milk.

In order, therefore, to feed cow's milk to infants, these differences must be corrected, and the correction of them causes further differences, which have in turn also to be corrected; the process, therefore, is a complicated one.

Before considering the means adopted to alter the chemical composition of cow's milk, it would be proper to state that there is a common but false belief that milk from one cow is the best for infants' use. The principle that underlies this belief is perfectly right. It is, that it is desirable to obtain milk of uniform composition, but it has been found experimentally that milk of the same cow varies in its composition during twenty-four hours, and that it is in reality more likely that a mixture of the milk from several cows will show a more constant analytic result than that from one single animal. Jacobi and others have stated that the chances of infection from tuberculosis through the medium of milk can only be lessened by feeding from a large number of cows.

In order to render the character of cows' milk similar to that of human milk, it is necessary to reduce the amount of casein in cows' milk. This is usually done by treating the milk with water, thus diluting it; but sometimes lime-water is used, for the reason to be stated immediately.

Second, the proportion of fat in cows' milk is less than in human milk, and it has been still further reduced by dilution. Therefore, it is necessary to add to it fat in some form or other, and this is commonly done by adding cream.

Thirdly, sugar must be added to cows' milk in order to bring the lactose up to the proper level. It has been held by some that it is necessary to use milk-sugar for this purpose, but there seems to be little doubt that cane-sugar will serve the purpose quite well, or even better.

In the fourth place, according to Jacobi, it is necessary to prevent as far as possible the great coagulating effect that the ferment of the infants' gastric juice has on the casein of cows' milk, and this is satisfactorily accomplished by adding an alkali, such as lime-water, or some mucilaginous material, such as barley water. In this way the casein curd is rendered loose and flocculent and more like that of human milk.

Dr. Meigs, of Philadelphia, advises the preparation of the following mixture: Cream, 2 oz.; milk, 1 oz.; lime-water, 2 oz.; sugar-water, 3 oz.; the latter is made by dissolving about 2¼ oz. of milk-sugar in a pint of water.

Condensed cows' milk is simply cows' milk that has been evaporated to one-fourth of its volume and sterilized, nothing at all being added to it. Then again, there is a form in which the milk is not only condensed, but has also the addition made to it of about 50 per cent. of cane-sugar. When it is also borne in mind that the composition of condensed milk varies with the season of the year, great fluctuations must occur in its chemical constitution.

Condensed milk must also be diluted with water before it is fit for use, and this dilution may entirely disarrange the proportion of the component parts of the fluid. For this reason it is found that even where infants appear to thrive on condensed milk, their apparent good health is due to an excessive deposit of fat, and not to a sufficient supply of albuminoids; and they are in the long run more prone to disease than babies fed on the breast, or on cows' milk properly prepared.

The above remarks apply with less force to that variety of condensed milk which is made from sterilized fluid and then sweetened, but even this preparation requires for digestibility to be diluted some ten times, and this reduces its nutritive value to a dangerous degree.

At times we must resort to various methods of feeding, until we find the proper method upon which a baby will thrive, and so it is that we have: 1, humanized milk; 2, sterilized milk; 3, pasteurized milk; 4, peptonized milk.

1. Humanized milk is simply cows' milk diluted with a certain amount of whey and with some cream. It is prepared in the following way: A pint of milk is set aside in a cool place until the cream rises to the surface. This is skimmed off and kept, and to the milk remaining is added enough rennet to curdle it thoroughly. The whey is strained off from the curd and added with the cream, previously separated, to a pint of fresh cows' milk, and the mixture is known as humanized milk. It is distinctly more digestible than ordinary diluted milk, and often agrees well with young infants, being given without any further dilution, in quantities suitable to the age of the infant. It may be employed exclusively during the first three months of the infant's life, and after that age may be used in combination with some farinaceous food.

2. Sterilized milk is that in which all germs tending to decompose it have been destroyed by exposure to a boiling heat at a temperature of 212 F. for a short period of time, from 15 to 45 minutes. Fresh cows' milk always contains impurities received from the cow or the atmosphere or from the vessels in which it is contained, though much care may have been taken to maintain absolute cleanliness. The milk is usually exposed to the action of steam or in a boiling heat from 5 to 45 minutes, and will keep about 24 hours. A fresh bottle must always be opened for each meal; if anything is left in the bottle after the baby has finished, it must be thrown out.

3. Pasteurized milk is simply steamed at a temperature of 167 to 170, for about 30 minutes, in other words, it is really sterilized milk at a lower temperature.

4. Peptonized milk, the fourth substitute for ordin-

ary diluted milk, is as simple a preparation as sterilized milk. It consists of milk which has previously been partially digested by the addition of some preparation of a digestive ferment, among the best known of which are Benger's liquor pancreaticus, Fairchild's peptonizing powders, etc. The milk should be diluted to some extent before being peptonized; but it is not necessary to dilute to such an extent as has been recommended for ordinary cows' milk. Generally, even for an infant two or three days old, the addition of an even quantity of barley water will be sufficient, and when a baby is two or three months old, a dilution of two parts of milk, with one part of water, will be digested with comfort.

In France there is a law forbidding any one to give solid food of any kind to infants under a year without the written authority of a qualified medical man.

Jacobi says, whatever I have here brought forward, is certainly not to disparage the boiling of the milk; it is to prove the danger of relying on a single preventive when the causes of intestinal disorders are so many. It is true, however, that the large majority of the latter depends on causes which may be met by sterilization; but not by sterilization only; also by pasteurization, that is, heating the milk to 70 C., or 165 F., and keeping it at that uniform temperature for 30 minutes, a procedure which destroys the same germs that are killed by a more elevated temperature, without much change in flavor and taste.

One of the questions connected with the employment of sterilized or pasteurized milk is this, whether the milk to be used for a child ought to be prepared at home, or whether the supply may be procured from an establishment where large quantities of milk believed to become immutable by sterilization for an indefinite period, are kept for sale. In regard to this problem Flugge plainly expresses his regrets that "we have allowed ourselves to be guided by people who are neither hygienists nor physicians, but chemists, farmers or apothecaries, and whose actions have been based on three false beliefs. Of these the first is that boiling for three-quarters of an hour destroys germs; the second that whatever bacteria remain undestroyed are innocuous, and the third, that proliferating bacteria can always be recognized by symptoms of decomposition." Nothing is more erroneous. Soxhlet himself, the German originator of sterilization, knew at an early time, that the fermenting process is now and then but partially interrupted by boiling, that butyric acid may be found in place of lactic acid, that a strong evolution of gas may be caused after such boiling, and that such milk may give rise to flatulency. Aye, milk which happens to contain the resistent spores of bacteria becomes a better breeding-ground for them by the very elimination of lactic acid, and the longer such sterilized milk is preserved and offered for sale, the worse is its condition. It may be true that these conditions are not met with very frequently, but an occasional single death in a family caused by poisonous milk will be more than enough. Therefore, the daily home sterilization is by far preferable to the risky purchase from wholesale manufacturers who can not guarantee, because in the nature of things they can not know the condition of their wares.

Another alteration of a less dangerous character, but far from being desirable, is the separation of cream from sterilized milk which is preserved for sale. Renk[1] found it to take place to a slight extent during the very first weeks, but later to such a degree that 43.5 per cent. of all the cream contained in the milk was eliminated.

Sterilization has been claimed to be no unmixed boon, because of its changing the chemical constitution of milk. Still, the opinions on that subject vary to a great extent, the occurrence of changes being both asserted and denied by apparently competent judges. But what I have said a hundred times is still true and borne out by facts, viz., that no matter how beneficial boiling, or sterilization, or pasteurization may be, they can not transform cow's milk into woman's milk, and that it is a mistake to believe that the former, by mere sterilization, is a full substitute for the latter. It is true, that when we can not have woman's milk we can not do without cow's milk. There is no alleged substitute that can be had with equal facility or in sufficient quantity. But after all it is not woman's milk. Babies may not succumb from using it, and may seldom appear to suffer from it; indeed, they will mostly appear to thrive on it, but it is a makeshift after all, and requires modifications. Hammarsten was the first to prove the chemical difference between the casein of cow's and woman's milk. Whatever was known on that subject at that time I collated in Gerhardt's "Handb. d. Kind," vol. i, 1875, (2 ed. 1882). But lately Wroblewski demonstrated the difference in solubility of the two milks. Woman's casein retains, during pepsin digestion, its nuclein—proteid rich in phosphorus—in solution, it is fully digested; in cow's casein the nuclein is not fully digested, a "paranuclein" is deposited undissolved and undigested.

Henry A. Bunker, in an article on the modification of cows' milk, says that the difficulty of the digestion of the casein of cows' milk in some children has seemed to be the resistance to the infant's digestive powers, even after the partial hydration supposed to be brought about by hydrochloric acid and heat. In all such cases the fecal evacuations were white, hard and dry, such as so often occur on a plain sterilized milk diet. In many of these cases, these dry, scybalous masses would frequently set up mucous diarrhea giving rise to severe colicky pains.

The only evidence of partial hydration by the acid and heat would seem to be the fact of increased nutrition in spite of these difficulties. Professor Chittenden[2] maintains and proves, by a beautiful laboratory experiment, that the products of gastric digestion have the power of combining with more hydrochloric acid than the original proteid, for as soon as proteolysis commences, the products so formed begin to show their greater affinity for acid by withdrawing acid from its combination with the native proteid, a supposition which is necessary to account for even the starting of the proteolytic process. Further, it is evident that proteoses and peptones combine with a far larger equivalent of acid than the native proteid-albumin, in the experiment, is capable of. This, doubtless, depends upon the cleavage of the large proteid molecule into a number of smaller or simpler molecules, each of the latter, perhaps, combining with a like number of hydrochloric-acid molecules. However this may be, it is evident that the products of pepsin-proteolysis combine with a larger amount of hydrochloric acid than the mother proteid, and that the transformation of the latter, at least under the conditions of the experiment, is a slow and gradual process.

It will be remembered that the original method proposed the hydration of the milk-proteids by hydrochloric acid and a rather prolonged boiling. Twenty drops of a 10 per cent. hydrochloric-acid solution were added to one pint of water and one quart of milk, and this mixture was to be kept at boiling temperature for about twenty minutes. The addition of a larger amount of the acid, unless the milk was quite fresh, was found to result quite frequently in curdling the milk. It was also found that the acid so added, up to the point of saturation or breaking, exists as combined acid, as was evident from the failure of reagents to show free hydrochloric acid in the completed mixture.

---

[1] Arch. f. Hyg., xvii.

[2] Cartwright Lectures on Digestive Proteolysis, 1894.

The indications that the hydration secured by this method is not always sufficient to meet the requirements of certain infantile stomachs and the fact that usually in such cases the nutrition is increased in spite of incomplete and painful digestion, seemed so strongly confirmatory of the results of Prof. Chittenden's researches, that I determined to copy, in part, his experiments on HCl saturation, as applied to the proteids of milk.

To this end, milk was prepared in the original way, except that the twenty drops of dilute hydrochloric acid were added in a one-half, instead of one, pint, watery solution, and slowly but intimately mixed with one quart of milk. This mixture was brought as rapidly as possible to the boiling temperature and then set aside until another half pint of water was prepared with twenty drops more of the acid. This was added to the previously boiled milk and acid, stirred thoroughly and again brought to the boiling-point. The result thus obtained was a thoroughly palatable milk, with no taste of having been boiled, and gave no indication of free hydrochloric acid with Gunzberg's reagent. Rudisch's plan is similar to the latter.

Proteids in excess are indicated by the presence of curds in the stools. This is the most frequent cause of colic in infants. Sometimes there is diarrhea, more often constipation when the proteids are in excess. The excess of proteids frequently causes vomiting and so does an excess of both fat or sugar. If, therefore, after reducing the percentage of proteids, fat or sugar, vomiting still persists, then we must feed the baby with smaller quantities. Thus, we may have to give a four-ounce bottle where a six-ounce or a five-ounce feeding causes vomiting. Certain rules can be laid down; if an infant does not thrive, that is, does not gain in weight without showing any signs of indigestion, then the proportions, i. e., percentages of all ingredients, should be gradually increased, chiefly the proteids, however, for the latter is the most important element in an infant's food. An infant soon after birth was put on modified milk, containing:

Fat	2.00
Milk-Sugar	5.00
Albuminoids	0.75
Lime-water	1/16

I ordered eight feedings, two ounces in each. As the child was constipated, soon after we increased the formula to the following percentages:

Fat	2.50
Milk-sugar	6.00
Albuminoids	1.00
Lime-water	1/16

As the stools did not change, the fat was increased to 3 per cent., other ingredients the same. The child gained but three ounces in weight in five weeks, had greenish, curded stools, and had distinct evidence of intestinal indigestion. It also vomited curds. The general condition of the child was one of extreme irritability, with very little sleep. Hand-feeding was stopped. The child's alimentary tract was thoroughly cleaned, and a wet-nurse secured. This was when the baby was six weeks old; the child nursed well, gained six ounces the first week, eight ounces the second, and weighed fourteen pounds when it was four and a half months old. The child improved until it was seven months old, when suddenly the weight remained stationary. A specimen of breast milk was sent to John S. Adriance, the chemist of the Nursery and Child's Hospital, who found the following percentages:

Fat	2.0
Sugar	7.431
Proteids	.882
Ash	.162

Specific gravity 1031; reaction, alkalin.

It is very evident that the deficiency in albuminoids or proteids is accountable for the stationary weight. The child did not gain an ounce in one month. We discharged the wet-nurse, and resorted to hand-feeding, when the child's general condition changed, and she is bright and well to-day.

In another instance, a child had been nursed by its own mother for three months, and had gained in weight regularly at the rate of six and seven ounces per week; the stools were normal in quantity and quality, when suddenly the child appeared to be colicky, was restless at night, had green stools, and did not appear to thrive. For two consecutive weeks the child did not gain in weight, and a specimen of breast milk was sent to the Pediatrics Laboratory. Mr. R. W. Bailey, the chemist, examined the specimen with the following result.

Fat	2.43
Proteids	1.25
Sugar	6.51
Ash	.20
Total solids	10.39

Specific gravity, 1027, reaction, slightly alkaline.

The percentage of fat and proteids is so low, that it was very plain to me why this child did not increase in weight. On putting the child on an oatmeal and top-milk mixture, the digestion improved, the child's sleep was better, and the weight increased.

Another case was that of a nursling, brought to me with a history of excessive crying, greenish stools, cheesy curd in the stools, vomiting, restlessness, and a general condition of malassimilation; I asked for a specimen of breast milk, which Mr. Bailey kindly examined, with the following result:

Fat	4.32
Sugar	6.22
Proteids	1.80
Ash	.19
Total solids	12.53

Reaction, neutral.

The general history of the case showed that the child was fed every time it cried, and thus it was evident that overfeeding was the real cause of the trouble in this case, for I learned that the child frequently nursed for hours at the breast, and was also allowed to go to sleep with the nipple in its mouth. Whenever the child cried it was fed, frequently as often as every half hour, so that in this case, whilst the quality of the breast milk was absolutely normal, as demonstrated by the chemical examination, it required only the judicious interval for feeding to give the child's stomach proper time for the assimilation of its food.

65 East Ninetieth Street.

LIGHT AND SEATING IN THE SCHOOL.[*]

C. ZIMMERMANN, M.D.

Oculist and Aurist to the Milwaukee and the County Hospitals.

MILWAUKEE, WIS.

Although we know that our vision very closely depends in its acuity on the degree of illumination, we have not arrived at establishing a definite law as to the relation of sight and intensity of light which might be formulated in mathematical terms. Experiments were made in that direction as early as 1754, by the celebrated astronomer, Tobias Mayer, of Goettingen. He changed the distances of a candle from ½ to 13 feet from certain systems of lines, and ascertained the distances in which he still could see them. From this he calculated the visual angles and found them, that is, the vision, at an inverted ratio to the sixth roots of the intensities of light. One hundred years later Aubert found that vision increases at a little faster rate than the logarithms of the intensities of light. Another method, adopted by Schmidt-Rimpler, Carp and Cohn, was to note the decrease of sight by putting smoke-colored glasses—the numbers 1 to 6—before the eyes of school-children. They observed great individual differences. The sight was relatively more impaired by decreasing illumination with increasing age, and in short-sighted than in normal eyes. More recently Uhthoff,[1] on the suggestion of von Helmholtz, made investigations, in von Helmholtz's laboratory, in Berlin, on the dependence of vision on the intensity of illumination in the different portions of the spectrum, and from his observations he constructed curves with the acuity of vision as ordinate axes, and the illumination as abscissas. The curves show great analogies in the different kinds of light from green toward red. At first they ascend very steeply, which means in the smaller intensities of illumination an enormously rapid increase of the acuity of vision with growing intensity of illumination. But, after a certain amount of the latter is reached, the curve turns rather fast and rises very slowly until it runs parallel with the abscissa. This signifies that, after a certain objective intensity of illumination is passed, a constantly decreasing ascendance of vision occurs, which finally reaches its limit although the intensity of illumination waxes more and more. Even a decrease of vision took place from glaring when the intensity of light became too high. From green toward violet a much greater variation of intensity is required for the same rise of vision than from green toward red. Uhthoff explains this from the predominance of yellow and green light in the artificial illumination. A visual power = 1.25, also decreases faster from green toward red with diminishing intensity of light than in blue light, and the difference is greater on the one side the nearer to the yellow portion of the spectrum, and on the other the nearer to the violet. This is in concordance with the phenomenon of Purkinje, namely, that after a blue and red area appear to the eye of the same illumination, the blue seems to reflect more light than the red, if the intensity of illumination is lowered, and less light than the red if the intensity of illumination is raised. The intensity of perception is a function of the intensity of illumination, which varies in the different kinds of light. The intensity of perception increases more slowly, and decreases more slowly for blue than for red, at the same variation of the objective intensity of light.

Last year H. Cohn published the visual results obtained from the examination of 50,000 school-children in Breslau, made out of doors. They were much higher than hitherto supposed. Almost one-half of all the pupils had normal vision, and more than one-third of all between twice and thrice the normal vision out of doors. The former was noted more frequently in girls, the latter in boys. Only 10 per cent. had vision below the normal. This shows the immense preponderance of intensity of light emanating from the open sky over the illumination in the room, and calls for a distinction of the true acuity of light in the open air from that in the schoolroom.

Practically it suffices to know that, if the illumination sinks we can not see as well, and, if we want to continue our work, we have to bring the book nearer to our eyes, so that the visual angle and the retinal images become larger. This, however, brings about a strain of the eyes by increased accommodation and convergence, which again causes congestion of the eyeballs and head. The latter is still augmented by interference with circulation and respiration, in consequence of the stooping position, by which the blood-vessels of the neck are compressed and the venous outflow from the head impeded. If this faulty position and strain of the eyes become habitual, spasm of accommodation, stagnation of blood in the eyeball, tension of the tunics and elongation of the eyeball will follow and myopia develop.

The question arises, how can we ascertain the right illumination, below which no school work ought to be allowed? For that purpose, H. Cohn, of Breslau, devised text types, on cards of a certain tint, which ought to be easily read by a healthy eye at six meters distant in sufficient daylight. Another test is the ability of a normal eye to read diamond type—D. = 0.50—at one-third of a meter—12 inches. If not, the schoolroom requires artificial light.

A new era in the investigations for illumination in the schoolrooms was advanced in 1883, by the invention of the photometer, by L. Weber, of Breslau, which allows an exact and rapid determination of the illumination on any seat of the room in daytime, and also for artificial light. The intensity of light is given in numbers of meter-candles, the intensity of one meter-candle being the illumination of a sheet of paper which is placed one meter distant from a normal candle—of stearine, of which six weigh a pound.

As mentioned above, the best illumination is furnished by the sky, and it is desirable that each desk receive as much sky-light as possible. The quantity of the latter can be ascertained by an instrument constructed by L. Weber, which he called *Raumwinkelmesser,* a meter of bodily angles. The *Raumwinkel* of a certain point of an illuminated desk is the solid angle formed by these lines or rays which are drawn from this point to the edges of the window and impinge on the sky. If this angle equals 0°, that is, if no sky-light falls on a certain place, the illumination of the latter will be—on cloudy days—1 to 3 meter-candles, reflected from the walls of the room. If it rises to 50°—with medium elevation angle—it corresponds to 10 meter-candles, an illumination which is considered as the minimum for a working place; this, however, allows only of three-quarters of the regular vision.

There can not be too much light in a school-room; it ought to be flooded with light, that the darkest place will have sufficient illumination on a dark day. The quantity of light depends on the size and number of windows, their relation to the space covered by the room, their exposure to the cardinal points and the situation of the schoolhouse with regard to its surroundings. The best arrangement would be if one wall of the schoolroom were entirely taken up by glass, like an atelier. Under all circumstances the windows ought to be as large as possible and reach up to the ceiling, since the upper part which admits the sky-light is the most important. They ought to be so large that at least 30 square inches of glass correspond to 1 square foot of floor, that is, 1 glass to 5 floor. Many older schoolhouses fall below this proportion, but some of the more modern ones exceed it. Architectonic ornaments must not encroach on surfaces which ought to be occupied by glass, and the jambs and piers between them must be as small as possible; these are made advantageously of iron, to insure the stability of the wall. The piers ought to be beveled toward the room, and the lower sill must not be less than 1 meter distant from the floor, so that the light does not glare from below.

---

[*] Read before the *Principals* and Teachers of the Public Schools of Milwaukee.

[1] Von Graefe's Arch., 32 and 36.

With regard to the situation, sky-light from the ceiling would be the best, This, of course, is only attainable in the top floor and is best utilized for drawing. In the lower stories the windows ought to be on the left side of the room, so that in writing there is no shadow from the hand. In addition to these, windows may also be in the rear, which, however, would disturb the teacher at his desk. If the room is very large the illumination will be increased if windows are also on the right side. These, however, must be placed high up, near the ceiling, and must not extend downward as far as on the left side, in order to avoid perverse illumination, which has an annoying effect on the retina and causes contraction of the pupils, associated with a strain of accommodation. The consequence of the latter is, that the objects have to be brought nearer to the eyes, which again creates a tendency to myopia.

The width of the schoolroom, that is, the distance of the windows from the opposite wall, must not exceed twice the distance between desk and upper window-sill. The situation of a schoolhouse at a free place without any surroundings is most advantageous. In large cities this, of course, is not always possible. But it ought to be a rule that the distance of surounding buildings from the schoolhouse be twice as long as their height. The lowest point of the sky which sends light into the room lies immediately above the edge of the roof of the opposite house. The light from this point penetrates farthest into the room. Every other point of the sky illuminates only portions of the room nearer to the window, so that the whole area of the sky-light which illuminates the room is bordered by lines drawn from this point to the upper and lower window-sills toward the desk. All portions of the room outside these lines are illuminated by the walls of the opposite buildings, and are, therefore, darker. It will readily be conceived that the higher the story the more sky-light it will receive.

The exposure of the windows toward the east and south gives the most intense light, some, however, prefer the north, to avoid annoyance by the sun. To obviate the latter, gray curtains are the best, one from above and one from below, or with the pole fixed in the middle of the window, so that it will not be necessary to darken the whole window. The tint of the walls ought to be light-gray.

As the school hours fall in the daytime, the question of artificial light is of minor importance. If it is used it must have no glaring effect, must not fall below 10 meter-candles, must be steady and not be hot. In that respect the incandescent light is preferable, as it does not consume the oxygen of the air and vitiate it. The glass of the lamps ought to be lightly ground, to remove the glaring effects of the wire. A group of lamps may be placed in the center of the ceiling, with a porcelain reflector above them, and a sufficient number of them distributed over the remainder of the ceiling and along the cornices.

Next to good light, the most important reform in school hygiene is the correct seating of the pupils. Not only from an orthopedic standpoint it deserves especial attention in order to prevent curvatures of the spine, but also with regard to the prevention of short-sightedness, by maintaining the proper distance of the eyes from the reading and writing objects. Besides that, the position must be the most natural one in which the body is most at ease, and which, therefore, can be endured for continuous work. The body can only remain at rest in a sitting posture, if the point of gravity, which lies in front of the tenth chest-vertebra, is in a perpendicular line above a base drawn through both seat-bones, which form the lower part of the pelvis and are the rotation points of the trunk. Any deviation of the point of gravity forward or backward requires a third point of support as a guard against the unstable equilibrium thus brought about. In the forward inclination this will be the front edge of the seat, but the muscles of the pelvis which will help to support the body in that position will soon tire, and, for relief, the chest and elbows will lean on the desk. The falling backward must be prevented by a back-rest, which ought not to be higher than the lower lumbar vertebra. If there is positive horizontal distance between desk and seat, the more will the trunk fall forward and deviate from the correct upright position. We have positive distance when a perpendicular line from the posterior edge of the desk falls some horizontal distance forward from the perpendicular line dropped from the front edge of the seat. In the construction of desks positive distance must, under all circumstances, be avoided, and must be converted into negative distance, that is, the front edge of the seat must reach under the desk, namely, 3 to 5 cm. forward from the perpendicular line dropped from the back edge of the desk. The vertical distance between desk and seat must be adapted to the individual in such a way that in the erect position the eyes remain 40 cm. distant from the desk, which is also about the distance of the eyes from the elbow, when hanging down. The distance of the latter from the seat-bone is one-eighth of the length of the whole body. From this the difference between desk and seat will be found if 4 to 9 cm. are added to one-eighth the height of the pupil. The feet must rest on the floor, from which it follows that the seat must be as high as the leg, measured from the sole to the inner bend of the knee, and as long as the thigh is long, from the inner bend of the knee to the back, with a width of at least 33 cm., to secure a sufficient support of the seat-bones and the thighs. It should be slightly concave, to prevent sliding forward. Reading a book lying horizontally, requires rolling of the eyes downward, which soon becomes tiresome, or stooping of the head forward, which is also faulty. Thus an inclination of the top of the desk of 45° would be best for reading, but not for writing;

to facilitate the latter an inclination of 1 to 6, or 10° is preferable. To meet the requirements of different individuals for correct sitting according to the principles set forth, desks and seats only which permit of ready and separate adjustment will give satisfaction. The best forms are those of the Chandler Adjustable Chair and Desk Company, of Boston. If the adjustment is once made it can not be altered by the pupil, if the key to it is withheld from him, and the desk and chair are screwed firmly to the floor. The Chandler desk leaves free space for the feet of the pupil, while the single standard desk presents some obstruction. In the back of the Chandler chair the central support is curved forward at the proper height to furnish the requisite support to the sacrum and the lower lumbar vertebræ, and thus counteracts the tendency of the pelvis to rock backward.

A table of dimensions and measurements is given as a guide for the arrangement of the desk and seat, based upon the tables of Erismann and Fahrner, and similar to that of Priestly-Smith. The directions for using the table are: Measure the height of the scholar; then find in the table the number that most nearly corresponds to it, and directly under it in the same column will be found the figures required for the different adjustment. The top of the desk can be made adjustable, allowing the pupil to stand between the desk and the seat when standing. It complicates, however, the mechanism, causes noise, requires time for adjustment, and is not necessary, since the pupil may rather step into the aisle, which allows him a better and less encumbered position.

Even the best constructed seats and desks can not prevent children assuming faulty positions, if not carefully watched. Thus the duty of the teacher will remain to admonish his scholars to sit erect.

SOME REMARKS ON THE PLANTAR REFLEX, WITH ESPECIAL REFERENCE TO THE BABINSKI PHENOMENON.*

J. T. ESKRIDGE, M.D.

Alienist and Neurologist to St. Luke's Hospital; Consulting Alienist and Neurologist to Arapahoe County Hospital, and Neurologist to the U. P., D. & R. G., and C. & S. Railroads.

DENVER, COLO.

Believing that the duty of the specialist in this association, working in a special line other than surgical, is to bring forward for discussion, observations and recent discoveries on mooted points that will aid the railroad surgeon and physician in the diagnosis of certain diseased conditions, I shall attempt to give the generally accepted views, of neurologists at least, on the value of the "Babinski sign," the pathological plantar reflex; or, better yet, slow extension of the great toe, with or without extension and separation of the other toes, as an aid in diagnosing disease in certain portions of the central nervous system.

My observations have been made on 830 cases, 380 in hospital and 450 in private and consulting work. Besides, 2550 cases taken from my old records, I have utilized for the purpose of determining the frequency of the plantar reflex in nervous diseases in general. I wish to express my indebtedness to Drs. Delahanty, Hall, Sewall and Freeman for the privilege of investigating the plantar reflex in their cases in the Arapahoe County Hospital, and to the resident physicians of that institution for the intelligent assistance freely rendered me by them; also to Dr. Hopkins for permitting me to observe cases under his care in St. Anthony Hospital; likewise to Dr. Lemen for allowing me to utilize the U. P. patients in St. Joseph's Hospital. I wish to thank the nurses in training in St. Luke's and Arapahoe County hospitals and some of the graduate nurses of these institutions for permitting me to investigate their plantar reflexes.

The Babinski sign is a comparatively new one, even in neurological diagnosis, and I do not fear of being accused of bringing a subject worn threadbare before an association composed mainly of railroad surgeons and physicians.

I wish to state, before going further, that I do not intend to discuss theories in this paper. My object will be to present facts and draw conclusions that I hope may aid in the diagnosis of disease in certain portions of the central nervous system.

The Normal Plantar Reflex in the Adult and the Method of Eliciting It.—If I were to include the whole phenomena of the plantar reflex I should have to note the contraction of several of the thigh muscles and some of the leg muscles which usually contract before the toes are flexed. My remarks are for railroad surgeons and physicians, and not for the neurologist. I shall, therefore, limit, for the most part, what I have to say to the movements of the toes. With this limitation, the normal plantar reflex consists in flexion of one or of all the smaller toes and frequently of the great toe on moderate stimulation of the plantar surface of the foot. The flexion sometimes delayed for a brief moment after stroking the foot is rapid, usually most marked in the outer toes, may be limited to these, but is often accompanied by flexion of the great toe. As a rule, a little firmer stroking of the plantar surface of the foot is necessary to cause flexion of the great toe than of the smaller toes. It must be remembered that flexion of the toes is usually accompanied or immediately followed by inversion and dorsal flexion of the foot at the ankle. Care must be taken not to mistake this for extension of the toes. Strange as it may seem, I have seen this error made on more than one occasion.

Precautions Necessary in Eliciting the Plantar Reflex.—In the first place the leg must be in a comfortable position, and so placed as to prevent any of the muscles of the leg or foot being put on the stretch. If the patient is nervous, and apprehensive of being hurt, it is wise to distract his attention from your investigations by engaging him in conversation. The same object may be accomplished by covering his eyes and beginning the examination by testing his tactile sensation with a camel-hair pencil. After his attention becomes concentrated on this method of procedure, the plantar surface of the foot may be gently stroked, and in the majority of instances the patient, not suspecting the object of the physician, will answer: "I feel that." The stroking should be the lightest that will elicit the reflex, but at the same time if the gentle stroking fails to cause any plantar reflex, the irritation should be increased in vigor until one is satisfied that there is no plantar reflex present. The plantar surface may be irritated on the outer or middle portions, stroking from the heel toward the ball of the foot, or from the outer to the inner surface just posteriorly to the ball of the foot. Stroking the inner side of the plantar surface often causes the most contraction of the toes, but it has the disadvantage of giving rise to greater movement of the foot, inversion and dorsal flexion at the ankle. The finger-nail, or what I have found better, the quill holder of a camel-hair pencil, answers every purpose for an object with which to stroke the foot. If the patient's attention is not directed to what one is doing when he is testing the plantar reflex, voluntary and semi-voluntary movements of the foot and leg are least likely to complicate the results. The plantar surface of the foot should be dry and warm when the reflex is tested.

---

* Read in abstract at the Seventh Annual Meeting of the Academy of Railway Surgeons held in St. Paul, Minn., Sept. 5-6, 1900.

The normal plantar reflex may be modified by age, sleep and stupor or coma, especially in children, mental development, the condition of the plantar surface, dropsy of the feet and legs, trophic changes in the feet from old nervous lesions and by ankylosis of the toes.

Age.—In the healthy adult the plantar reflex, if present, may be lessened during sleep and other unconscious states, but it is probably always attended by flexion of the toes. In infants, before they begin to walk, the plantar reflex, while brisk as in the adult, is somewhat irregular, and may be attended by contraction, or by extension and separation of the toes. Collier[1] states that in infants the extension of the toes continues in healthy subjects up to the end of the first or second year; in the weakly until the fourth year, and is occasionally found up to the sixth or twelfth year when the child is asleep. In the latter group of cases the adult reflex returns as soon as the child is awakened. Personal experience in examining the plantar reflex in infants has proved very unsatisfactory to me. The feet of infants when exposed are always in constant motion, especially while under examination. The movements consist in extension and separation of the toes, followed by rapid flexion. It has often been very difficult for me to determine whether the toe movements were more extension than flexion. I have not been able to examine the plantar reflex of infants while they were asleep in a sufficient number of cases to enable me to draw any conclusions. In one I found the reflex absent so far as the toes were concerned, in two there was flexion of the toes followed by extension, and in three the toes quickly extended and separated, followed a few seconds later by flexion.

Cohn, Schüler, Watson, Paul, Sachs and others have apparently met with equally unsatisfactory results in examining children in health.

Delayed or arrested development is often attended by an irregular plantar reflex. I have recently seen a case of idiocy in a boy of 6 years in whom the infantile type was preserved, and another in a girl of 20 years in whom the infantile type was present when the patient was asleep, but the irregular adult type appeared on arousing the girl.

The plantar reflex may be lessened or abolished by anything that lessens the sensibility in the plantar surface, such as lesions in the nerves, cold and dampness, dropsy and trophic changes of the feet and also by ankylosis of the toes.

Variations of the Plantar Reflex in Apparently Healthy Adults.—Is the plantar reflex ever continuously absent in healthy adults, and may it be absent in one foot and present in the other under such circumstances, even when all the necessary precautions are taken *in testing for the reflex?*

Collier says: "If the preceding points are taken into consideration, I think that the common statement that the plantar reflex is not rarely found completely absent in healthy subjects will not be confirmed."[1] Fraenkel and Collins say: "We have never found it absent without adequate attributable cause, such as peripheral neuritis."[2] Knapp and Langdon hold the same view.[2]

On the other hand, Blocq and Onahoff think it is frequently absent.[3] Schüler, Cohn, Walton and Paul found the plantar reflex absent in 10 per cent. of healthy subjects.[4]

I have records of 100 healthy subjects in whom I carefully investigated the plantar reflex and found it absent on both sides in 9 per cent., after excluding a series of 7 subjects whose cases will be referred to presently. In the 100 subjects I endeavored to take every necessary precaution. If the feet were cool or moist I had them rubbed with a coarse towel until the plantar surfaces were dry and red. Then after waiting a few minutes I covered their eyes and carefully tested the plantar reflex. Fearing that the vigorous rubbing with a coarse towel might have abolished the plantar reflex for the time being, I re-tested the cases some hours later, and still the results remained the same.

The most remarkable results were obtained on testing the plantar reflex in 7 healthy, strong and vigorous nurses while on duty in the wards of the Arapahoe County Hospital. The feet of all were warm and dry. In 1 only was the plantar reflex present in both feet; in 1 it was absent in one foot and present in the other —flexion—in 5 the reflex was absent on both sides. These tests were made at about 5 p.m., after the nurses had been on their feet all day. Thinking, possibly standing on the feet for so many hours might have something to do with abolishing the plantar reflex, I visited the hospital the following morning at 7:25 a.m., before the nurses had gone on duty, and re-investigated the reflex, but to my surprise there was no change to record in the results that I had obtained the previous afternoon, except that in the one with normal reflex in one foot, the reflex was found absent in both feet. These results would lead one to suspect that occupation has something to do with modifying the plantar reflex in health and possibly in disease.

I should remind you that these observations had to do with the toe movements alone. The curious results that I obtained on examining the plantar reflex in 7 nurses determined me to examine the plantar reflex in as many nurses as I should be able to obtain for investigating the reflex under consideration. I shall have, therefore, some 47 other nurses in whom I have to report the condition of the plantar reflex before I close this paper.

It is well known that the plantar reflex may soon be exhausted in many healthy subjects, that it may be present at one time and absent in another, but that it may be absent without any appreciable cause is important to bear in mind.

In answer to the second inquiry: "May the plantar reflex be absent in one foot and present in the other in healthy subjects, even when all necessary precautions are used in testing the reflex?" Dr. Knapp is of the opinion that such a condition is not found unless there is some disease of the nervous system. Drs. G. L. Walton and W. E. Paul, in their excellent article in the June number of the *Journal of Mental and Nervous Disease*, of the present year, give the results of their examinations of the plantar reflex in 100 normal subjects as follows: "All, or some, toes—generally the outer—of both feet flexed in 75 per cent.; no movement, 10 per cent.; flexion on one side, no movement on the other, 15 per cent." In the 100 apparently normal subjects of which I have notes plantar reflex was present on one side and absent on the other in 5 cases.

It seems to me that if one will investigate the plantar reflex in a number of healthy subjects he will have to admit that this reflex may be absent in one or both feet in a small percentage, probably from 8 to 12 per cent.

The Babinski Phenomenon or Pathological Plantar Reflex.—This consists in rather slow and deliberate extension of the great toe with or without extension and separation of some or all of the other toes on stroking the plantar surface, as is done in attempting to test the normal plantar reflex. The pathological reflex differs from the normal reflex in three ways. 1. The great toe makes the greatest and sometimes the only movement. 2. The movement is one of extension and separation, the latter most marked in the smaller toes. 3. The movement, especially well marked in the great toe, is much slower than in normal flexion and gives rise to the impression of deliberation. I can best illustrate the difference by testing the normal and pathological reflex in the subjects whom our president, Dr. Wheaton, has kindly arranged to have present at this session of the Academy.

In 1896, Babinski first called our attention to the extensor movement of the great toe with or without extension or separation of the other toes in connection with lesions of the pyramidal tract. His first paper seems not to have attracted much attention, as it was apparently overlooked in the proceedings of a biological society.[5] He continued to investigate the subject, and two years later described certain characteristics of the pathological movement, namely, that extension is slower than flexion, and that while flexion is stronger in healthy subjects when the inner side of the plantar surface is stroked, the reverse of what holds true in extension of the toes. The second communication[6] attracted a great deal of attention, especially on the continent of Europe and to a much less extent in England. I have been unable to find any records of an American investigating the pathological reflex of Babinski, prior to the publication of Dr. James Collier's paper on the plantar reflex—both physiological and pathological. This paper appears in *Brain,* vol. xxii, part 85, p. 71, for 1899.

In the *Journal of Mental and Nervous Disease* for June, 1900, p. 307, Drs. G. L. Walton and W. E. Paul give a rather long list of investigators who have studied the plantar reflex in health and in various diseases.

Two papers, one by Walton and Paul,[4] devoted to the consideration of the plantar reflex, and one by Fraenkel and Collins,[2] giving a short consideration to this reflex, were read before the recent meeting of the American Neurological Association. In the discussion that followed a number of the prominent members participated. You see that the pathological or Babinski plantar reflex has not been prominent before the medical profession for more than two years, yet it has received general attention from the neurologists, both in Europe and America, as a diagnostic sign.

A résumé of the results obtained by various investigators of the pathological plantar reflex may be summed up in a few paragraphs. I must thank Drs. G. L. Walton and W. E. Paul for making this easy for me, as I shall still further condense their condensed summary.

Babinski in his first report—1896—simply called attention to the fact observed by him that in pyramidal disease, stimulation of the plantar surface of the foot on the affected side was followed by extension of the great toe, and often by extension and separation of the smaller toes. He termed this *le phénomène des orteils.* Two years later—1898—he called attention to further particulars, the most important of which was, that the extensor movement of the toes is slower than flexion, and that flexion is stronger when the inner side of the plantar surface is stroked, the converse being true of extension. He reported mixed varieties which he thought were pathological and physiological, as stroking one part of the foot would cause flexion and another part extension, the first part of the reaction being flexion, followed by extension. Again, he noted in some cases extension of the inner toes and flexion of the outer ones resulting from the same stroke. His observations were confirmed by fourteen observers, including Collier, of England, and Langdon, of America. There seemed to be a unanimity between the fourteen observers, in that the toes, especially the great toe, would be slowly extended on stroking the plantar surface of the affected foot in diseases of the pyramidal tract.

Collier, while he maintained that the toes extended in pyramidal disease in the adult on stroking the plantar surface, that the movement is slow, that the great-toe movement preceded the movement of the smaller toes, found a similar movement in infants, except that it is quicker. He also found that extension of the toes is the only reflex movement in total transverse lesion of the cord. He was able to obtain the extensor plantar reflex in a case of tetanus and in a case to which he had given large doses of strychnin. Babinski reported a case of strychnin poisoning in which the extensor plantar reflex was present.

"Cestan and Le Sourde found the extensor reflex in 92 per cent. of the 68 hemiplegiacs examined, and in all the 35 cases of spinal disease implicating the pyramidal tract—except one case of neuritis also—in all the 6 cases of syringomyelia, and in all the 30 cases of infantile hemiplegia and diplegia." [4]

Dr. F. W. Langdon says: "The constancy of 'extensor' plantar reflex on the paralyzed side in organic cerebral hemiplegias is such as to render the Babinski sign here a very valuable diagnostic aid, especially in the unconscious patient. The sign is present in recent and old hemiplegias, appearing usually within a few hours after the stroke and before the knee-jerks return."[7]

In looking over Langdon's 110 tabulated cases in which the plantar reflex was tested, I find in one case of right hemiplegia the right plantar reflex was irregular, or absent, and left absent. In a case of left hemiplegia, right plantar reflex was flexion, left, slight extension or absent. In another case of left hemiplegia the plantar reflex on both sides was flexion, but the paralysis had nearly all passed away. In one case of left hemiplegia, complicated by meningitis and gumma, the plantar reflex was flexion, most pronounced in the left. He also reports one case of hysterical contracture, with hemiplegia of the entire left side—face, arm and leg. The plantar reflex in this case was right, flexion; left, extensor. He states that the affection of the left side could be made to disappear on hypnosis. If this case, No. 58 in his table, was hysterical in character, the extensor reflex did not mean organic disease in this case, at least. Personally, I do not believe that a paralysis and contracture which disappear under hypnosis must necessarily be functional in character.

On the other hand, let me give the views of three other observers who are less inclined to accord to the extensor plantar reflex so great a value in diagnosis. Giudiciandrea states that he found plantar extension in hysteria and in normal individuals. Schüler found extension plantar reflex—notably of the great toe—in 8 per cent. of the men examined, in 10 per cent. reflex was absent, and in two indeterminate; in normal women 4 per cent. extension, in 10 per cent. absent, and in 6 per cent. doubtful. In 8 cases of pyramidal-tract disease extension was present and pronounced. In children the reflex was either absent or rather unsatisfactory. Cohn found flexion in 60 per cent. of healthy persons; extension of the great toe, with either extension or flexion of the others, in 20 per cent.; absent reflex in 10 per cent.; and variable movements in 10 per cent. He found the plantar reflex generally absent in infants, but when present it was usually extension; usually extension in recent cases of apoplexy; in 4 cases of spinal spastic disease, extensor reflex in 2. In one case of hysterical hemiplegia he found extension on the paralyzed side.[4]

Schwab gives Cohn's conclusions as follows: "In the majority of all persons an irritation of the sole of the foot is followed by flexion of the toes. In lesions of the lateral tract of the spinal cord of an organic character, an extension reflex is to be observed. In no way, however, can this phenomenon be regarded as a certain pathognomonic symptom for the recognition of such disease."[5]

In the two recent papers which treat of the plantar reflex in disease of the pyramidal tract, Collins and Fraenkel state: "From our observations, we have corroborated the findings of Babinski, Van Gehuchten, Collier and others, that this type of plantar reflex—the extensor—is not found in normal individuals, and that when carefully examined with the precautions mentioned above, it is found only in cases in which there is unmistakable evidence of disease of the pyramidal tract."

In paragraphs numbered 3 and 4 of Walton and Paul's conclusions, we read as follows: "3. The Babinski reflex obtains in about 70 per cent. of hemiplegics and diplegics, and in approximately the same percentage of cases with disease involving the pyramidal tract in the spinal cord." "4. The Babinski reflex—deliberate and constant extension of the great toe, with or without extension and separation of other toes—is never present in health, and our observations lead us to doubt its existence in either functional or organic nervous or other disease not implicating the pyramidal tract."[4]

Personal Observations on the Plantar Reflex, both in Health and in Disease.—From 1878, when I first began to pay especial attention to the diseases of the nervous system, till the spring of 1899, the time when I first became familiar with Babinski's investigations, results and conclusions, I paid strict attention to the plantar reflex, but failed to observe the important points to which Babinski has so recently called our attention. During the past eighteen months, or since the spring of 1899, I have investigated the Babinski phenomenon in nearly every case that I have seen at my office, in consultation, or in St. Luke's Hospital. It was not until a few weeks ago that I utilized any of my cases seen and studied prior to my becoming acquainted with the Babinski phenomenon and the methods and precautions necessary in investigating it. In looking over my records from 1878 till 1898, I find the plantar reflex was registered as follows: Plantar reflex R. present or absent; L. present or absent, with a note as to whether the foot was flexed toward the dorsal or plantar surface.

It will be seen that I can utilize my old material only as to whether the plantar reflex was absent or present.

I have been unable to look up the records of all my old cases of nervous and mental diseases, but have been able to ascertain whether the plantar reflex was absent or present in 2550 recorded cases. In the hospitals I have studied the plantar reflex with especial reference to the Babinski phenomenon in 380 cases. In office and consultation practice and in private work in St. Luke's Hospital I have studied the plantar reflex in 450 patients suffering from organic or functional nervous diseases, or from insanity, a total of 3380, 2550 of which are of little importance in the study of the Babinski phenomenon. I shall first give a short analysis of the 2550 old cases of nervous and mental diseases.

Tumor of the brain, 100 cases: In 40 cases the pyramidal fibers were involved either directly or indirectly, and the plantar reflex was present in all on the affected side until just before death, when on account of exhaustion they disappeared. On the unaffected side of the plantar reflex was present in 38 cases and absent in 2. When the patients became greatly exhausted just before death the reflex disappeared on both sides. In the 60 in which the pyramidal tracts were not affected the plantar reflex was present in 54 cases; in 3 absent and in 3 the reflex was present on one side and absent on the other.

Intradural tumors of the cord, 5 cases: Plantar reflex was present in 3, absent late in the disease in one and present on one side and absent on the other in one.

Abscesses of brain, 12 cases: In all, the pyramidal fibers escaped: 4 of the cases were seen early in the disease and the plantar reflex was present in these; 8 cases were seen when the patients were becoming exhausted; the plantar reflex was present in 6 and absent in 2.

Cerebral meningitis, 75 cases: Sixty of these were tubercular; 50 in children, 10 in adults, 7 syphilitic and 8 from suppuration of the middle ear. In the 50 tubercular cases in children from a few months to 12 or 13 years of age the plantar reflex was absent in all after coma set in. In the 10 tubercular cases in adults the plantar reflex was absent in 8 and present in 2. Patients greatly exhausted. In the 7 syphilitic the plantar reflex was present in 4, absent in 2 and irregular in one. In the 8 from suppuration of the ear the plantar reflex was present in 4 and absent in 4.

Syphilis of the brain and cord, 100 cases: In 56 plantar reflex was present, in 30 absent and in 14 irregular.

Hemiplegia from vascular lesions, 150 cases: On the paralyzed side plantar reflex was present in 130 cases, absent in 10 and irregular in 10.

Bilateral thrombosis, 2 cases: Plantar reflex was present in both.

Posterior spinal sclerosis, 100 cases: Plantar reflex, although in some cases it was feeble, was present in 35, absent in both feet in 48, absent in one foot and present in the other 17.

Multiple neuritis, 20 cases: Plantar reflex present in 8, absent in 12.

Anterior poliomyelitis, 40 cases: Plantar reflex present in 24 cases, absent in 16 in which changes were well marked.

Neuritis of the sciatic nerve, 10 cases: Plantar reflex was present in all.

Pressure neuritis of the sciatic nerve, 20 cases: Plantar reflex present in 18 cases and absent in 2.

Pressure neuritis of the nerves of one or both legs, 12 cases: Plantar reflex present in 8, absent in 4 cases.

Myelitis, 60 cases: In 10, cervical, plantar reflex was present in all. In 20 dorsal, plantar reflex was present in all. In 30 dorso-lumbar plantar reflex was absent in all.

Complete transverse lesion of the cord, 6 cases: No plantar reflex was present.

Spinal caries, 50 cases: Plantar reflex was found in all above the lumbar region, absent in all cases of the dorsolumbar region with distinct cord symptoms.

Friedreich's disease, 8 cases; Plantar reflex was present in all.

Paralysis agitans, 8 cases: Plantar reflex was sluggish in all.

Hysteria, 50 cases: Plantar reflex was present in 29 cases, absent in 21.

Neurasthenia, 100 cases: Plantar reflex was present in 90 cases and absent in 10.

Nervous irritability—commonly known as simple nervousness, 93 cases: Plantar reflex was present in 85 cases and absent in 8.

Chorea, 50 cases: As far as I could determine, the plantar reflex was present in all, but the wild movements of the feet made in some cases accurate observation impossible.

Epilepsy, 100 cases: Plantar reflex was present in 93 and absent in 7.

Traumatism to the head, 60 cases: Plantar reflex was manifest in 40 and absent in 20.

Traumatism to spine and cord, 40 cases: Plantar reflex was present after the shock was over in all cases in which the injury was above the dorsolumbar region, provided the cord was not completely severed.

Deaf-mutes, 25 cases: Plantar reflex was present in 22, absent in 3.

MENTAL DISEASES.

Dementia, 200 cases: Plantar reflex was present in 80, absent in 104, present in one foot and absent in the other in 16.

Paretic dementia, 200 cases: Plantar reflex was present in 120, absent in 50 and irregular in 30.

Mania, 200 cases: Plantar reflex was present in 190, absent or irregular in 10.

Melancholia, 200 cases: Plantar reflex was present in 60, absent in 120, and irregular or absent in 20.

Paranoia, 250 cases: Plantar reflex was present in 200 cases, absent in 20, irregular in regard to the two sides in 30.

Feigning, 30 cases: Plantar reflex was present in 26 cases, absent in 2, present on one side and absent on the other in 2.

Stuporous melancholia, 20 cases: Plantar reflex was absent in all.

Melancholia attonita, 10 cases: Plantar reflex was present in 6 cases and absent in 4.

Weak-minded children, varying in age from 8 to 15 years: Plantar reflex was present in 40 cases, absent or irregular in 10.

Imbecility, 75 cases: Plantar reflex was present in 60 cases, absent or irregular in 15.

Idiocy, 25 cases: Plantar reflex was present in 19, absent or irregular in 6.

The average percentage of the presence or absence of the plantar reflex in each of the above individual nervous diseases is approximately as follows:

Tumor of the brain, present 85, absent 15; intradural spinal tumors, present 100; the plantar reflex was lost in all before death.

Abscess of the brain, present 83.3, absent 16.7; meningitis in stage of coma, present 13.3, absent, 86.7; syphilis of the brain, present 70, absent 30; hemiplegia from vascular lesions present 90, absent 10; bilateral thrombosis, present 100; posterior spinal sclerosis, present 52, absent 48; lateral sclerosis. present 100; anterior poliomyelitis, early present 90, absent 10; multiple neuritis, present 40, absent 60; in inflammation of the sciatic nerve, present 100; pressure neuritis affecting the sciatic nerve, present 90, absent 10; pressure on several nerves of one or of both legs, present 66.7, absent 33.3; myelitis, present 50, absent 50; complete destruction of cord, absent 100; caries of spine above dorsal region, present plantar reflex, 100; in dorsolumbar with involvement of cord, absent plantar reflex 100; Friedreich's disease, present 100; hysteria, present 58, absent 42; neurasthenia, present 90, absent 10; nervousness, present 91.5, absent 8.5; chorea, present 100; epilepsy, present 93, absent 7; traumatism to head, present 66.7, absent 33.3; traumatism to spine, present 70, absent 30; deaf-mutes, present 88, absent 12; dementia, present 48, absent 52; paretic dementia, present 60, absent 40; mania, present 95, absent 5; melancholia, present 33.3, absent 66.7; paranoia, present 90. absent 16; feigning, present 93.3, absent 6.7; stuporous melancholia, absent 100; melancholia attonita, present 60, absent 40; weakmindedness, present 80, absent 20; imbecility, present 85.7, absent 14.3; idiocy, present 76, absent 24.

The average percentage in which the plantar reflex was present or absent in the 2550 old recorded cases is as follows: The plantar reflex was present in one or both feet in 77.8 per cent; it was absent in both feet in 22.2 per cent.

I have found from observation that the simple presence or absence of the plantar reflex in organic nervous disease especially, but sometimes in the functional, depends largely on the vigor or physical exhaustion of the patient at the time the test is made. For instance, vigorous physical exercise for fifteen or twenty minutes in the gymnasium apparently does not modify the plantar reflex, but, on the other hand, laborious work carried to the point of almost complete exhaustion will abolish the reflex. In the case of multiple neuritis the plantar reflex is present and vigorous extremely early in the disease. In nearly all severe cases, at the height of the disease, especially if there are great physical exhaustion and trophic changes in the feet, the plantar reflex is almost invariably absent. After diphtheria, if the plantar reflex becomes excessive, I have learned to fear multiple neuritis.

Tumor and abscess of the brain are no exception to the general rule, that in complete exhaustion preceding death the plantar reflex usually disappears.

Since my attention was called to Babinski's observation on the plantar reflex, which was about eighteen months ago, I have carefully examined the reflex with especial reference to this phenomenon.

I examined 100 patients in the hospital, apparently free from any nervous or other trouble that should affect the plantar reflex, using every necessary precaution, and I obtained the following results: Plantar reflex present, 86; absent, 9; absent on one side and present on the other, 5. There was no Babinski phenomenon in any of these.

The above percentage of absent plantar reflex in the normal subject is in line with the results of Walton and Paul, and with those of several other investigators, but contrary to the views of Knapp, Langdon, Collier, and Collins and Fraenkel. The number of cases in which I found the plantar reflex in one foot and absent in the other is less than the results obtained by Drs. Walton and Paul.

(To be continued.)

COSTA RICA, ITS PHYSICIANS AND MEDICAL INSTITUTIONS.

N. SENN, M.D., PH.D., LL.D.
PROFESSOR OF SURGERY RUSH MEDICAL COLLEGE.
CHICAGO.

The short midwinter vacation I am spending in Costa Rica has afforded me an excellent opportunity to study the diseases of this little republic and to become acquainted with its leading medical men and its most important institutions devoted to the care of the sick. Costa Rica is the smallest of the Central American republics. Its present population does not exceed 300,000, and is made up largely of Indians, Jamaica negroes and Spaniards, with a small sprinkling of whites from the United States and the different European countries. The coast on both sides is low and swampy to the base of the mountains. The low lands supply the world with bananas, and the mountain sides are covered with coffee plantations. The interior is mountainous and picturesque, a Switzerland plus the tropical forests and impenetrable jungles. Along the coast the heat is depressing, being greatly aggravated by the ever-present atmospheric humidity. At an elevation of from

3000 to 4000 feet, the climate is delightful, the temperature ranging from 70 to 80 F. throughout the year. The nights are always cool. San José, the capital, is located in a beautiful and fertile valley at an elevation of nearly 4000 feet above the level of the sea. Its present population is 20,000. It is lighted by electricity and has an efficient telephone system and an electric tramway. Cartago is the next largest city, with a population of 13,000. Port Limon is the most important seaport town and is connected with San José by a narrow-gauge railroad, constructed by Mr. Keith, an American capitalist, at an expense of $15,000,000. Nearly all of the large business firms and plantations are owned by foreigners, who have contributed largely to the rapid development of the resources of the country. The government and laws of the country are modeled after those of the United States.

THE COSTA RICA PHYSICIANS.

There are at the present time few parts of the civilized world which are not amply supplied with medical men who are able and willing to serve the sick. Costa Rica is well supplied with doctors, native and foreigners. I take this occasion to warn our recent graduates not to come to this country with the expectation of gaining fame and amassing a fortune in a few years. Those who have done so have, in the majority of cases, been sorely disappointed. There are very few rich people in this country and even the well-to-do are far apart. A man with $200,000 is considered wealthy, and $10,000 is looked upon as sufficient to place a family in easy circumstances. More than 75 per cent. of the population are poor, and at the end of the year have little, if anything, left with which to pay for medical services. There are about sixty doctors in Costa Rica, most of whom live in the larger cities. There are over thirty physicians in San José, with a population of less than 25,000. Then, too, the fees are very small. The average charge for a visit in this city does not exceed $1.00, and nearly every doctor finds at the end of the year when he collects his bills that nearly one-half of them are worthless. The poor are often content with one visit, even in grave and prolonged cases, more especially those who expect to pay their bills.

Surgical work is estimated on the same scale. One hundred dollars for any kind of an operation is regarded by surgeon and patient a handsome fee. Fortunately Costa Rica has no medical college. A number of years ago some efforts were made in this direction, but the best elements in the profession vetoed the project. For some reason that even the native doctors do not comprehend, Madrid is not selected as the place to obtain a medical education, as we would naturally take for granted, considering language and the fact that the best families are of Spanish descent. Most of the Costa Rican physicians received their medical education and training in the United States and England, only a very few have visited the universities of Germany and France. The prominent doctors occupy a high social position and command a powerful political influence. Dr. Duran served as vice-president and, when the president was forced to resign, filled the highest position in the gift of the people. Cabinet positions have been repeatedly occupied by the ablest and most popular physicians. As a rule, the professional relations are harmonious. The spirit of progress and advancement is manifest by occasional visits to the great medical centers of the United States. There can be no doubt that the projected construction of the Nicaragua canal will be one of the many means to establish a closer relationship between the medical profession of our country and that of Costa Rica.

ACADEMY OF MEDICINE OF COSTA RICA.

The only medical society in Costa Rica is the National Academy of Medicine. The president for 1900 is Dr. Bonnefil. The weekly meetings are held in the capital city. It is a source of regret that a few of the very best men have not seen their way clear to become members. The excuse offered that the transactions lack in scientific work is hardly tenable, because those that can not learn should consider it a great privilege to teach. The Academy is invested with certain rights granted by the government; for instance, the members nominate and elect the Board of Medical Examiners. Every physician who intends to practice his profession must pass a satisfactory examination before this board. No one is admitted to these examinations without a diploma from a medical college in good standing.

HOSPITALS.

Hospitals have been established in all of the larger cities. There are two small hospitals in Port Limon. An effort is now being made to consolidate them into one, a move in the right direction. One of these little hospitals is maintained by the United Fruit Company and the other by the railroad, and both are in charge of Dr. Steggall, the most prominent practitioner on the coast. There is only one hospital in San José to which the sick poor of the city and district are admitted. It is built on the pavilion plan and has a capacity for one hundred patients. It is in charge of the Sisters of Charity Saint Vincent de Paul, with Sister Josephine at the head. The ample surrounding grounds have been appropriately beautified by skillful gardening. Dr. Nunez, the most prominent physician in the city, is medical superintendent; Dr. Duran, chief surgeon. The remaining medical staff consists of: Dr. Th. M. Calneck, consulting surgeon; Dr. M. Bonnefil, consulting physician; Drs. F. Zumbado and G. Jiminez, assistant surgeons; Drs. E. Rojas and J. M. Soto, medical attendants.

Dr. Nunez is a leader in politics as well as in his profession and everything pertaining to the public welfare. Dr. Duran, his classmate and partner, is an expert and successful operator. The morning I visited the hospital he had commenced the difficult task of entering the bladder without a guide, in a case of impermeable stricture of the urethra. The patient, a young man, was greatly debilitated by the secondary consequences of the stricture, septic cystitis and phlegmonous inflammation of perineum and scrotum; the latter had resulted in numerous fistulæ. It was, as he said, the most difficult case he ever encountered. His skill, patience and perseverance were finally rewarded by success, when he emptied the bladder of a large quantity of ammoniacal urine and established free drainage. The operating room is modern and furnished with a good instrument supply and the necessary facilities for aseptic and antiseptic work.

Recently a very much-needed addition has been made in the form of a maternity ward and it was my pleasure to see two babies which first saw light in the great room which is destined to become a refuge for many an anxious, homeless mother. The institution, like all those in charge of the Sisters of Charity, is scrupulously clean. The food is plain, but palatable and substantial. It is time that the sisters, like those of the same order in the United States, should establish and maintain a training-school for lay nurses. I made a strong plea to accomplish this most desirable object and trust that it made a sufficient impression on Sister Josephine to at least seriously consider the propriety of such a change in the nursing of the sick inside and outside of the hospital. There is only one ward set aside for private patients, who pay from $7 to $14 per week, including medical attendance. The pharmacy is in charge of one of the sisters.

LEPER COLONY.

Costa Rica, like all Central and South American states, harbors its full quota of lepers. It is estimated that at the present time there are scattered throughout the state about 150 to 200 lepers. The adjoining United States of Colombia, with a population of 2,000,000 has 35,000 lepers. The disease invaded Costa Rica from that source about fifty years ago, and since that time it has become diffused over the entire state. On paper, segregation has become a law, but like many other laws it has never been carried into effect. The leper home consists of a number of old buildings on an eighteen-acre lot near the western limits of the city, and contains 30 inmates. It is in charge of Dr. Toledo, who is at the same time the sanitary inspector of the city. The sexes are about equally represented. It is a noteworthy fact that all Costa Rican lepers are the subjects of the nervous form of the disease, while the three Jamaica negroes are suffering from the advanced stages of the tubercular variety. Dr. Toledo is now testing the therapeutic value of a new vegetable remedy, but so far no positive results have been observed.

INSANE ASYLUM.

The insane asylum is a state institution to which the poor insane from all districts are admitted. It can accommodate 150 patients, and at the present time contains 135 inmates. Ample provision has also been made for private patients of the first, second and third class, who at a comparatively small expense can avail themselves of all the advantages of a private asylum. This institution is known by the euphonious name of Asilo Chapui in memory of a saintly priest who died one hundred years ago, and who donated a large tract of land to the city. For the last eleven years the asylum has been under the case of Dr. Maximilian Carl Bansen, a German physician of more than national repute. To the great learning, executive abilities and enthusiasm of Dr. Bansen must be attributed the great success of this institution. The hospital is surrounded by a magnificent flower and vegetable garden. The floral wealth of this garden can be approximately estimated from the fact that it contains 160 varieties of roses. The remaining part of the grounds supply the asylum with coffee, bananas and other tropical fruits. According to the statistics, including many years, 50 per cent. of those admitted recover their mental equilibrium, and of those discharged cured only 2 per cent. have been known to suffer from relapse. This marvelous result is secured by the methods employed in the treatment. Dr. Bansen places the greatest stress on abstracting the patient's mind by giving him employment which does not tax the mental faculties, that is, physical exercise and mental rest. About 40 per cent. of his patients are thus employed. Dr. Bansen regards the excessive use of the strong alcoholic native liquor as the most important etiologic influence in provoking the disease. He looks upon coffee and all stimulants as harmful in its treatment. The asylum is a model of cleanliness and its entire management bears testimony to the great executive abilities of its director. Although the physicians in every part of the state send patients to the asylum, practically it is left for Dr. Bansen to determine their mental condition and reject or admit them.

PREVAILING DISEASES.

The two diseases which afflict this country the most and which intimidate the foreigner as well as the native, are malaria and yellow fever. Malaria of the most malignant form prevails throughout the entire year in the banana districts, along both coasts, but the physicians here are willing to admit that no part of the state is entirely free from it. The pernicious form of malaria is often mistaken for yellow fever, and vice versa, something that has given rise to a great deal of confusion at the seaport towns under quarantine regulations. The Jamaica negro possesses the greatest intrinsic resistance to malarial infection and he is the one upon whom the banana grower must rely almost exclusively in tilling his lands. The negro knows this only too well, hence, his haughty demeanor and sense of independence. The physician's here do not look upon the mosquito as the sole carrier of the disease, as they are frequently called upon to treat malaria in localities where there are no mosquitoes. In pernicious malaria they rely almost entirely on deep subcutaneous injections of bisulphate of quinin in 40-grain doses.

Colon and Panama are the hotbeds of yellow fever and the free communications between these places and the seaport towns of Costa Rica are responsible for frequent outbreaks of the disease. Segregation and disinfection are not observed to the extent they should be in preventing the spread of yellow fever. Port Limon has gained an unenviable reputation as a focus of infection, largely by mistaken diagnoses. That the disease frequently makes its appearance at that point there can be no question, but that many cases of malarial fever have often closed the doors of commerce is equally true. Isolated cases of yellow fever occasionally have been seen in the mountainous regions and it is not always easy and sometimes impossible to trace the source of infection. Goitre is very common among women, young and old. Gonorrhea and syphilis are prevalent to an alarming extent and are by no means limited to the lower classes, although the negroes furnish the largest percentage. Pulmonary tuberculosis and tuberculosis of the lymphatic glands, bones and joints appear to be quite rare. Rheumatism is very common and affects the inhabitants of the low lands as well as of the mountainous regions. Barbadoes leg is quite frequently seen, but is more common in the South American countries. Cholera infantum claims many victims throughout the entire year, and it is said that less than 50 per cent. of the infants reach childhood. Faulty feeding is the cause of this enormous infantile mortality.

QUARANTINE.

There is certainly something wrong with the quarantine regulations between the ports of New Orleans and Limon. The health authorities of the port of New Orleans enforce quarantine against the port of Limon seven out of twelve months every year, to the great detriment of the shipping interests. The fact is the New Orleans authorities have no faith in the health officer of the port of Limon and the doctors employed by the United Fruit Company. To a certain extent the action of the Board of Health of Louisiana is justifiable, as formerly the United Fruit Company usually employed recent graduates in medicine, who often have never seen a case of yellow fever and who are not competent to differentiate between this disease and grave attacks of malaria. The same can be said of most of the physicians sent by the board of health of other states to the seaports of Central America. The quarantine system at the port of New Orleans is, however, too complicated. There are two quarantine stations under the jurisdiction of the State Board of Health which often at a distance decides whether or not a vessel should be detained, which often gives rise to great confusion and not infrequently enforces unnecessary quarantine. The best solution of this important and difficult question would be to place the port of New Orleans under the jurisdiction of the Marine-Hospital service, which has done such excellent work in other states in guarding our country against invasion of yellow fever and other infectious diseases from foreign ports.

In conclusion I desire to recommend to my colleagues who are in need of midwinter vacation the hospitable shores and beautiful climate of Costa Rica. The cool nights in the mountainous region can not fail in securing rest for the brain as well as the body, and in restoring the nervous energies which are so heavily taxed by an onerous and exacting practice. They will meet in San José and elsewhere a cordial reception on the part of their colleagues and will leave the country, as I shall do in a week or two, with many regrets and the most pleasant memories, fully satisfied that the time was well spent.

San José, Dec. 30, 1900.

Surgical Treatment of Bubonic Plague.—In a report to the Surgeon-General of the Marine-Hospital Service, Acting Asst.-Surgeon W. Havelburg, of Rio Janeiro, Brazil, states that the clinical registry at the Paula Candido Hospital during the period from June 1 till August 31 shows that there were 221 plague patients treated by extirpation of the infected glands, of whom 45 died, giving a death-rate of about 20.8 per cent. And of 143 patients with solitary infected buboes, treated in the same manner, 23 died, showing a death-rate of about 16 per cent. The diagnosis in all the above cases was confirmed by two bacteriological examinations, one before removal to the hospital and the other after admission to the wards. Serotherapeutic treatment was instituted in a number of other cases, but the effects of operating displayed such favorable results that injection of serum in the others was deemed unnecessary. The necropsy reports in the cases that died showed buboes that were inaccessible to operations, being scattered in the mesentery or deeply situated in other tissues.

Sero-Agglutination in Tuberculous Effusions.—Courmont announces that sero-agglutination does not occur in any effusion except those of tuberculous origin and that it is inversely proportional to the virulence and rapidity of the infection. He noted it in 74 per cent. of all cases of tubercular pleurisy, in a proportion of 1 to 5 or to 20 or even higher, but it was absent in all cases of tubercular miliary pleurisy, peritonitis or meningitis. The effusion in experimental tuberculosis does not agglutinate if the culture inoculated was virulent, but with an attenuated culture is was very pronounced, as much as 1 to 600 in the dog, for instance.—*Sem. Méd.*, November 28.

SATURDAY, JANUARY 19, 1901.

MALARIAL FEVER.

Malarial fever prevails especially where heat, moisture and decomposing vegetation are present because these are favorable to the existence of mosquitoes. Malarial infection occurs most commonly after sunset, because mosquitoes, after remaining in hiding during the day, set out upon their depredations after dark. The infection is not widely diffused in a horizontal, oblique or vertical direction because mosquitoes do not fly far from their place of origin, and especially not to a great height. The infection is not conveyed, but rather hindered, by winds, because the insects do not leave their hiding-places when the wind blows. Woods, instead of preventing, may be foci of malarial infection, because the mosquitoes make their hiding places in damp woods and trees.

A great advance was made when, in 1880, Laveran, a French army surgeon at Algiers, discovered the parasite of malarial fever, but it was not till fifteen years later that their complete life-cycle was demonstrated by Ross, a British army surgeon in India. The observations of Laveran were soon confirmed and elaborated by others, particularly in Italy and America. It has been shown that the malarial parasites are protozoan organisms belonging to the order of sporozoa and, by reason of their living at the expense of the red blood-corpuscles belonging to a special suborder known as hemosporidia. Members of this group, though not necessarily of the same genera and species, have been found in batrachia and reptiles, in birds and in mammals.

For a long time a warm discussion was waged as to whether the parasites were polymorphous varieties of a single organism or so many different and distinct organisms, but the consensus of opinion is at present in favor of the latter view. According to Celli there are in man at least three species: Two for the mild fevers—spring quartan and tertian—and one for the severe or estivo-autumnal fevers—tertian and quotidian. The individual identity of the several varieties of malarial parasites has been demonstrated by inoculations from man to man, the same febrile type only being reproduced in every instance. Of course, mixed infection is impossible, and may give rise to anomalous or atypical forms of fever.

It has been shown that in man, as in birds, the hemosporidia have two life-cycles: an asexual cycle in the blood of malarial animals, and a sexual cycle in the bodies of special mosquitoes.

For centuries it has been a popular belief that mosquitoes have something to do with malarial fever, and Koch found that a similar notion prevailed among the natives in South Africa. In 1848, Nott, an American, suggested that both yellow fever and malarial fever were conveyed through mosquitoes. A similar view was put forward by Allessandrini in 1870, by King in 1883, by Laveran in 1884, by Flügge in 1889, and by Pfeiffer and Koch in 1892. In 1894, and again in 1896, Manson proposed the view that the malarial parasites, in order to maintain their existence, must pass from man to another host, and he concluded that inasmuch as they are incapable of leaving the body through their own efforts and are not extruded in the excreta, they must be removed by some blood-sucking animal, which he believed to be a particular species of mosquito. Ross, then, in 1895 and 1897, was able to demonstrate the parasite in the stomach-wall of particular mosquitoes fed on malarial blood, and he was able also to convey the parasite through the mosquito to birds and to man. Ross' observations were at once verified and elaborated by Italian investigators and others and the evidence is now so complete that there can be no further doubt as to the part played by mosquitoes in the propagation and transference of malaria. If additional confirmatory evidence be wanting it can be found in the development of malarial fever in healthy individuals, in London, inoculated with malarial mosquitoes brought from Italy. Further, the disease did not develop in a number of observers who lived during the malarial season in an intensely malarial district of Italy, but merely protected themselves against the bites of mosquitoes, while the disease prevailed as usual among others in the same locality but not protected against mosquitoes. Not all varieties of mosquito, however, act as the definitive host of the malarial parasite, of which man is considered the temporary host. It is especially insects of the genus Anopheles, and particularly Anopheles claviger, also called maculipennis, although other varieties are capable of playing the same rôle. It is not known with certainty whether, apart from the intermediation of man, the malarial parasite may be transmitted from one mosquito directly to another, either from a parent mosquito to its offspring or from the body of a dead mosquito eaten in stagnant water by larvæ.

It may be conceived that certain conditions predispose to malarial infection apart from those that favor the existence of the infecting mosquitoes. Chilling of the surface of the body seems to be the most important of these, probably by lowering the bodily resistance. The spring is generally the season for mild cases and the autumn that for severe cases.

The Michigan Board of Examination and Registration has thus far put 43 American medical colleges on its list of reputable schools.

THE PRESENCE OF BACILLUS TUBERCULOSIS IN THE HEALTHY NASAL CAVITY.

Cornet's experimental work led him to state that infected dust is an important and dangerous factor especially to those in attendance on tuberculous patients, and that this danger lies first and foremost in tuberculous sputum that has become dry. In one of his series of experiments he collected 149 samples of dust from various places frequented by tuberculous patients, as hospital wards, private dwellings, streets, etc., and made inoculations into 392 animals. Fifty-nine animals became tuberculous, representing 40 samples of the dust, or a percentage of 26.8, while on the other hand 29 animals which were inoculated with dust from non-infected places, remained healthy.

An interesting series of experiments has recently been made by Flügge and his associates in Breslau with the object of showing, 1, the infectiousness of dust bearing dry powdered sputum, and 2, the infectiousness of fine droplets of mucus expelled by talking, sneezing, coughing, etc., when laden with tubercle bacilli. In the first series, carried out by R. Sticker, infected dust was blown into the faces of guinea-pigs and compared with like tests in which sterilized dust was employed. In the infected cases seven of the eleven animals became tuberculous, while those inoculated with sterile dust remained healthy. But he found the infectiousness of such dust to depend directly on the strength of the air current employed and the absence of moisture. The finest, lightest dust, when perfectly dry, was able to produce an inhalation tuberculosis under the influence of very weak currents of air.

Concerning the infectiousness of fine droplets of mucus laden with tubercle bacilli, uniformly positive results were obtained by Laschtschenko, Beninde and Heymann, each experimenting in a different way. In these experiments phthisical patients were made to cough or speak into the faces of guinea-pigs directly, or they were allowed to cough or speak near sterile plates or dishes containing sterilized salt solution, and this in turn was used for inoculation. It was found that the elements of distance and duration of exposure play most important parts in the dissemination of the germs, for only a few positive results were obtained from exposures made more than 1.5 meters away from the patient and then only after a considerable time. That the conditions in these experiments are actually present in hospitals, factories, counting-rooms, workshops and the like, where the occupants are at all crowded, there is no doubt; it would seem, as urged by Flügge, that this method of infection might largely be done away with if prophylactic measures were instituted.

Strauss first demonstrated in 1894 the presence of virulent tubercle bacilli in the nasal cavities of those who, being non-tuberculous themselves, were in more or less constant attendance on tuberculous patients. His experiments were made on house-physicians, nurses and non-tuberculous patients, and resulted in his finding the micro-organism in 9 of 29 persons examined, or approximately 41 per cent.

This work suggested the question of the presence of tubercle bacilli in the nasal cavities of healthy persons who did not have the care of the tuberculous at all, and were subjected to only the ordinary amount of infection to which every one living in a large city, especially, must submit. In carrying out this work Jones[1] examined 29 men all in good health, no tuberculous lesions being discovered on physical examination. The contents of the nasal cavities of each, consisting of mucus, solid particles, dirt, etc., were removed by sterile cotton swabs, from the nasopharynx outward, and washed into a test-tube containing 10 c. c. of a sterilized normal salt solution. This solution was then injected, under aseptic precautions, into the abdomen of a guinea-pig, the wound closed by collodion dressing, and the animal allowed to live until it died either from the effects of the inoculation or from other causes. Of the 30 animals inoculated death occurred in times varying from a few hours to eighty-six days. Each animal was examined carefully post-mortem and in the series 3 revealed a generalized tuberculosis of the viscera. This is approximately 10 per cent. of the cases.

In general, this series of experiments goes to show that virulent tubercle bacilli may be present in the nasal cavities of healthy persons in the ordinary walks of life, but not so frequently as in those who have the care of the tuberculous.

THE PURIFICATION OF SURFACE WATER-SUPPLIES.

The Committee on the District of Columbia of the United States Senate is investigating the relative merits of slow filtration through sand beds and rapid filtration in connection with the use of coagulants as applied to surface waters for their purification. The Engineer Department of the Army made experiments on the Potomac river water during the past year and recommended for the water-supply of Washington the adoption of a system of mechanical filtration with alum as a coagulant. The District Medical Society took exception to this recommendation and urged the construction of sand beds for slow filtration as giving better sanitary results.

From the hygienic standpoint the subject before the senate committee is not a difficult one. There is no question as to the efficiency of slow sand-bed filtration in removing bacteria from a polluted water and lessening the prevalence of typhoid fever among the communities using the filtered water. There is, on the contrary, a question as to the efficiency of mechanical filtration, particularly as to the removal of typhoid bacilli, for the installation of mechanical filtration plants in cities has not been followed by that marked diminution in the mortality from this disease which has been recorded in communities which have adopted the sand-bed filters. The mechanical filter is still in the experimental stage so far as concerns typhoid fever. Its effluent is clear and transparent, but this, from the sanitary point of view, is relatively a minor consideration, the object being to prevent disease and lessen the death-rate.

---

[1] Medical Record, Aug. 25, 1900, xlviii, 285-289.

The efficiency of the sand-bed depends on a slow and regulated filtration; that of the mechanical filter on the addition of alum to the water to clarify it. Carbonates in the water decompose the alum, precipitating the gelatinous aluminum hydrate which entangles clay and other particles constituting the turbidity, together with the bacteria which may be present. These are strained off by the passage of the water through the mechanical filter. It is the alum, not the filtration, which is actively concerned in the removal of the bacteria. If enough alum is added the effluent is clear and gives satisfactory results on bacteriological examination. If an insufficient quantity is added the effluent may be turbid and charged with bacteria. If too much is added or more than can be decomposed by the carbonates present, alum will remain in solution in the effluent as a most undesirable accidental constituent. With care at the water-works alum may no doubt be added to effect its purpose without a trace of it appearing in the effluent, but it will be conceded by all medical men that chemicals which would be injurious in excess should not be added to a water-supply if a satisfactory purification can be effected without their use; and the experiments of the Engineer Department on turbid Potomac river water have shown that such purification can be accomplished by slow sand-bed filtration.

A BAD SUPERSTITION.

According to a Toledo (Ohio) physician, some people in that city have a superstition against paying doctors' bills. They think if they pay him in full they will have to pay him again. "It may be all right," he says, "as a superstition but it is pretty tough on the doctors." This must be a very widespread superstition, and its existence must have been in the mind of the celebrated medical writer who dedicated his works "to all men who are free from superstition." A certain amount of superstition is excusable, in fact it seems almost unavoidable, and the above dedication hits a very limited number of individuals, if indeed any at all, if the term is taken in its widest sense. But the particular form of superstition mentioned above will not be encouraged by the medical profession.

THE SMALLPOX EPIDEMIC.

One of the most afflicted places in the United States appears to be the town of Decatur, Neb., with a population of 625, in which, and its near vicinity, there were reported in the health reports of the Marine-Hospital Bureau, 451 cases of smallpox between April 1 and December 14, 1900. It would seem that the antivaccinationists must have had full sway there, at least as regards revaccination. The small mortality—only four in all—reported would indicate a mild type of the disease, what is usually called varioloid, but does not lessen the peculiarity of the situation. It is a pity that so salutary a hygienic resource as vaccination has to be defended at the present time, and the epidemic of smallpox the country is now experiencing may have a good effect in reinstating it in popular favor. With "Christian Science" and Dowieism in the field, and with individual and organized antivaccinationists, there is still "chance for a pretty fight" in some communities before the public health is fully protected by compulsory vaccination.

TOO MUCH QUALIFIED.

It appears from an editorial note in the *Medical Press and Circular* that it is possible to be too well fitted for a medical position in Great Britain. In a recent competition for the position of resident house physician at Cardiff, Wales, the rejected candidate showed higher qualifications than his successful rival. When the selection was challenged it was argued on the part of the medical board who made the choice, "that when a man who was head and shoulders above his commanding officer was appointed to a subordinate post there could be no discipline." In other words, the lack of medical qualification of the superior officer should deprive the institution of the services of any better-qualified employees, the better qualified the worse fitted for the place. The plea that discipline would suffer under such conditions is an admission of executive incompetency or a slur on the loyalty and good faith of the better-qualified candidate, and is contemptible in either case. The fact that the resignation of the medical board was threatened when the directors overruled their rejection of the candidate does not speak well for their professional or scientific morals. Moderation in all things is sometimes good advice, but we never knew it applied especially to professional qualifications before.

A NEW YORK "AUNTIE."

A Brooklyn (N. Y.) homeopath, one Dr. Montague Leverson, is reported to have advised antivaccinationists to shoot down any one trying to vaccinate them or any member of their families. While the individual seems to be a general "auntie," and his influence is lessened to some extent as this fact is commonly appreciated, yet such advice is liable to create trouble when given to ignorant and fanatical people and can not therefore be condoned on any claims of the giver's irresponsibility. A still more serious matter, if true, is his statement publicly made that he had attended thirty cases of smallpox, some of them of the most virulent nature, without reporting them to the board of health. If he did this he is more than a blatant nuisance, he is a living danger to the community and needs the earliest possible attention on the part of the criminal courts. A man who goes about endangering the lives of those who come in contact with him by carrying the infection of a loathsome and fatal disease, who by his concealment of facts prevents the individuals and the community from protecting themselves from the same, and who further does all he can to advocate the neglect of all precautions, is a public enemy. We may perhaps try to consider him a fanatic and therefore only a dangerous fool, but if the criminal law can not touch him the lunacy law should; in any case, his mischief-making should be stopped. There are too many such individuals extant and it is possible that a dose of the criminal law would be the best prophylactic, if not cure, for this kind of lunacy.

THE EPIDEMIC OF INFLUENZA.

The epidemic of influenza that is now spreading over the country rivals, if it does not exceed, in extent and virulence that of 1890 and 1891. Indeed, there are some reasons to think that it may be attended with even a greater increase over the average mortality than was observed in that epidemic. The bacillus was detected by the Chicago Health Department as early as October, but it is only lately that the disease has taken on an especially severe type and it is probable that the same is true in other cities. In New York it was reported that the number of cases during the second week in January exceeded a hundred thousand, and similar reports of its frequency come from other sections all the way from the Atlantic to the Pacific. Cases of grip pneumonia seem to be particularly frequent with this epidemic and a very perceptible figure of direct mortality from influenza is noticeable in the death statistics. The mortality from other diseases following and directly induced or prepared for by influenza can hardly be calculated, but is likely to seriously affect the death figures, especially in the large cities. There will, in all probability, be very much lessening in the dividends of life-insurance companies for the present year on account of the epidemic. The infectiousness of grip does not appear to be thoroughly realized by the public and the chances of exposure are so great that it is possible that if it were, the spread of the disorder would be very little affected. This is no reason, however, why unnecessary chances should be taken and it might be well if people were generally warned that there are possibilities of its communicability. It is of still more importance that they should be instructed as to the risks of exposure during and shortly after an attack. Influenza is the young David among epidemics; while cholera and ordinary pestilences slay their thousands, it slays its tens of thousands through the other disorders it directly favors and incites.

AGGLUTINATION OF THE TUBERCLE BACILLUS BY TUBERCULOUS EXUDATES.

As previously noted in these columns considerable work is being done on the value in diagnosis of the agglutination of the tubercle bacillus by the serum of tuberculous patients. Arloing and Courmont have been interested especially in this subject, and Arloing has developed a special method for obtaining homogeneous cultures of the bacillus suitable for the agglutination test. Recently Courmont[1] published a summary of his observations during the past two years on the agglutination of the tubercle bacillus by various exudates, tuberculous as well as non-tuberculous. He believes that this method of serum diagnosis may be of great practical importance. The reaction is easily and rapidly obtained in the positive cases. Non-tuberculous exudates do not agglutinate the tubercle bacillus when diluted 1:5, while the majority of tuberculous exudates agglutinate the bacillus in dilutions of from 1:5 to 1:20. Exudates in especially virulent cases of tuberculosis sometimes do not give the reaction, and in certain benign cases of tuberculous pleuritis the reaction may be absent in the beginning but it may appear later on toward the period for recovery. There is no constant relationship between the agglutinating power of the blood-serum and the exudate in these cases—the serum may be agglutinating while the exudate is not, and vice versa. The agglutinating properties of tuberculous exudates of experimental origin correspond closely to those observed in human serosities. Hence a serous fluid that gives the reaction at a dilution of 1:5 is in all probability of tuberculous origin; absence of the serum reaction is merely presumptive evidence against tuberculosis. Further studies are desirable in order that material may accumulate from which desirable conclusions may be drawn. A comparative study of the agglutinating powers of the blood-serum and of the pleural tuberculous exudates would probably be of considerable value.

OCCURRENCE OF TYPHOID BACILLI IN EXUDATIVE AND SUPPURATIVE PROCESSES AND IN THE FETUS.

The careful study by modern exact methods of the various inflammatory complications and sequelæ of typhoid fever has shown that bacillus typhosus may be the only micro-organism present. Its etiologic relationship in some of the processes here referred to seems firmly established. Pleurisy, a not common complication of typhoid fever, has been shown to occasionally depend upon the presence of the typhoid bacillus. Gordinier and Lartigau[1] describe a case of this kind. A purulent exudate had to be removed from the right pleural cavity by aspiration on three conditions. This fluid contained the bacillus in pure culture. The third week seems to be the favorite time of onset of typhoid pleuritis, the fluid in the majority of cases being purulent. Hemorrhagic and serofibrinous exudates also occur. Oscar Richardson[2] describes an instance of typhoid abscess of the mammary gland, developing during convalescence from typhoid fever; also a typhoid suppurative periostitis of the tibia under similar circumstances. He furthermore describes typhoid suppurative prostatitis and a pelvic abscess containing typhoid bacilli in two cases which came to autopsy. The typhoid pelvic abscess occurred in a tuberculous woman who had both typhoid and tuberculous ulcers in the intestines and also tuberculous salpingitis. These examples show that the pyogenic activities of the typhoid bacillus may unfold themselves in all possible localities. Richardson also describes two fetuses expelled prematurely in the course of typhoid fever in the mothers; in one typhoid bacilli were found in the liver, in the second they were more widely distributed. In all the cases mentioned in the foregoing the bacilli were agglutinated by typhoid serum in marked dilutions.

THE BACTERIOLOGY OF ACUTE APPENDICITIS.

It has long been the general opinion that the colon bacillus is the essential micro-organism in acute appendicitis. The presence of this bacillus in the intestinal contents and the frequency with which it has been found in acute appendicitis in pure culture have left little room for any other opinion. There has been an idea current for a long time, however, that possibly the colon bacillus is the result of a secondary infection and that its profuse growth rapidly kills off the principal pathogenic bacteria, namely the pyogenic cocci. This idea receives strong support in the recent study of the bacteriology of 100 cases of acute appendicitis by H. C. Low.[1] He made his cultures on Löffler's blood-serum. Agar plates, commonly used by many previous investigators, were found to be unreliable because they did not show cultures of all the organisms present. Streptococcus pyogenes or micrococcus lanceolatus was present in 79 per cent. of the cases, the colon bacillus occurred in 81 per cent. In cases under three days' duration the streptococcus was present in 81 per cent. and the colon bacillus in 62 per cent. In chronic cases the colon bacillus becomes more common, suggesting that its presence means secondary infection. It therefore seems probable that the streptococcus and allied pyogenic organisms are the essential factor in acute appendicular abscess and that the profuse growth of colon bacilli and other intestinal bacilli outgrow the cocci. One reason why other observers have found colon bacilli only in such large percentages of the cases is very likely the exclusive use of agar and bouillon media, which do not permit the growth of streptococci as well, by far, as blood-serum.

THE TONSILS AS A PORTAL FOR RHEUMATIC INFECTION.

Although a specific etiologic factor has not yet been isolated, it is generally agreed that acute rheumatism is an infectious disease, and it has of late more especially been pointed out that the tonsils often constitute the portal of entry. Whether any etiologic relation exists between acute, subacute and chronic rheumatism is a matter concerning which more doubt exists. It is possible that acute rheumatism proper, apart from various forms of infective arthritis, is a specific disease of uniform etiology, although it is held by some that it is really a variety of mild, attenuated pyemia. The other varieties of so-called rheumatism, it is suggested, may be due to a modification of the same infective process; or, at times, at least, they may not be rheumatic at all in the specific sense. The tonsils seem to have been the portal of entry not only for the articular infection, but also for myocardial infection; and possibly other apparently cryptogenetic processes owe their origin to this source. Nor is it necessary, as it appears, for the intermediating tonsils to be the seat of macroscopic or even microscopic disease. Further, the tonsillar affection may be some days old, and even recovered from, before the secondary complicating conditions make their appearance. At times the rheumatic manifestations proper may be so slight or transient as not especially to attract attention. Bruck[2] points out that an analogous mechanism may explain some of the cutaneous exanthems believed to be of rheumatic character, such as nodose erythema, multiform exudative erythema, and rheumatic purpura or peliosis, and he reports four cases in which rheumatic purpura was observed in association with tonsillitis. In all, the symptoms of the former followed almost imediately on those of the latter, although the difficulty in swallowing in three was so slight as to be almost unnoticed. In the remaining case the anginal symptoms were pronounced and articular effusion and petechiæ were observed to develop as the former subsided. In two cases there was also articular and muscular pain in the neck, the back and the upper extremities.

[2] Berliner Klin. Woch., 1900, No. 45, p. 1005.

THE RELATIONS BETWEEN ACUTE AND CHRONIC ARTICULAR RHEUMATISM.

While arthritis confined to a single joint, or involving a greater or lesser number of joints in varying distribution, may be due to a number of causes, acute articular rheumatism is to be looked on as a specific infectious arthritis whose etiologic factor, however, has not yet been positively identified. In the same way chronic rheumatism may be due to a multiplicity of causes and the question has been raised whether there is really any relation between the acute and the chronic articular disorder. Finally, subacute rheumatism occupies a scarcely less anomalous position. There seems to be a growing belief that often the three disorders named are unrelated, although agreeing clinically in some respects. Weisz,[1] on the other hand, contends not only that the acute and chronic articular forms possess certain features in common, but also that there is no material anatomic, clinical or etiologic distinction between chronic articular rheumatism and deforming arthritis. In the opinion of this observer, the commencement of chronic articular rheumatism can often be traced to an attack of acute polyarthritis. Although bacteria have been found in the joints in cases of both acute and chronic articular rheumatism, no one has, as yet, been agreed on as the exciting agent in either disease. Further, while fever is more commonly present and is more marked in cases of acute than in cases of chronic rheumatism, exceptions to and reversals of this rule occur. In addition, acute rheumatism is the more frequent in the young, chronic rheumatism in the old, and the former are the more susceptible to influences that cause elevation of temperature. As a rule, there is no essential difference between the anatomic alterations attending acute and chronic rheumatism. It appears that in the young, in whom acute rheumatism is the more common, the endocardium especially exhibits a tendency to permanent disease; while in the old, in whom chronic rheumatism is the more common, the articular capsule exhibits such a tendency; and the opinion is expressed that such differences as exist between acute and chronic rheumatism are of degree and not of kind, and are related in part to variations in age. This fact may explain the greater frequency with which chorea is associated with acute rheumatism. Among less common symptoms it is pointed out that cutaneous edema, rheumatic nodules, rheumatic perineuritis, changes in the cartilages and bones, attend both the acute and the chronic disease.

CURABILITY OF SCOLIOSIS.—K. Port says that when the growth of the bones has ceased any attempt at correction of curvature of the spine is absolutely hopeless.

Medical News.

ALABAMA.

DR. J. W. WILLIAMS, of the Wooley Springs region, was shot and seriously wounded December 10, but is now expected to recover.

THE BILL appropriating $25,000 to the Alabama-Bryce Insane Hospital at Tuscaloosa for the purpose of completing the department for negroes at Mount Vernon, referred to in a recent issue of THE JOURNAL, was passed by the senate without a dissenting vote.

SIX MOBILE PHYSICIANS, Drs. Charles A. Mohr, James G. Thomas, Vivian P. Gaines, Rhett Goode, city health officer; Paul J. M. Acker, county health officer, and L. Van Es, memmers of the board of health, at the request of the Mobile city council, have visited New Orleans and investigated the methods employed in that city for the inspection of meats and milk.

REPRESENTATIVE S. J. GRIFFIN, of Cullman county, has introduced in the Legislature a bill which seeks to regulate the practice of medicine in the state. The bill makes it a misdemeanor for any person to treat disease without having a license from a board of medical examiners authorized by law, and fixes the penalty at not less than $100 nor more than $500.

CALIFORNIA.

IN BAKERSFIELD, 8 new cases of smallpox from two foci were discovered December 31.

DR. WILLIAM B. LEWITT has been named as member of the San Francisco Board of Health, vice Dr. Louis Bazet, resigned.

THE CLASS TOWEL in schools has been tabooed by Health Officer Todd, of Oakland, who insists on individual towels for school children.

DR. LELAND E. COFER, U. S. M.-H. Service, who has served as quarantine officer at Port Los Angeles for some time, has been assigned to the charge of the marine-hospital at Honolulu, H. I.

ASSISTANT SURGEON-GENERAL J. H. WHITE, U. S. M.-H. Service, is in San Francisco investigating the charges made by certain newspapers of the city against Quarantine Officer Kinyoun.

DR. H. B. STEHMAN, Los Angeles, has received a handsomely engrossed, morocco bound, copy of resolutions recently adopted by the board of managers of the Presbyterian Hospital, Chicago, in accepting his resignation as superintendent after fourteen years' service in that position.

GEORGIA.

THE DEATH-RATE of Atlanta for 1900 was 14.73 per 1000; for 1899, 17.13 per 1000. Violence caused 8.57 per cent. of the 1930 deaths during the year.

"DR." C. R. KING, of the "New Medicine Company" of Atlanta, has been fined $100 and costs by Judge W. T. Newman, of the United States Court for sending obscene matter through the mails.

COUNCILMAN DR. THOMAS D. LONGINO, Atlanta, proposes to substitute for the present system of seven ward physicians at a salary of $50 per month each, a health officer with the requisite number of assistants.

ILLINOIS.

THE CITY PHYSICIAN of Springfield, Dr. Archie W. Barker, reports that during the last year he had prescribed for more than 1500 patients and had made more than 600 visits.

AN INFERNAL MACHINE addressed to Dr. Sylvester A. Coffman, Hume, was received by his brother a few days ago. Fortunately the mechanism had become disarranged and no explosion occurred when the box was opened.

THE GOVERNOR in his message recommends the enactment of a law making boards of county commissioners boards of health in their respective counties. He also recommends legislation for the establishment of a sanitarium for the treatment of tuberculosis.

SMALLPOX is reported at Fountain Green, Hancock county, 3 cases; Granite City, Madison county, 12 cases with 3 deaths: Collinsville, Madison county, 3 cases; and Bellaire, Crawford county, 1 case. Bloomington is combating an invasion of the disease, which is said to have been brought to the city from Missouri by the colored crew of a work-train.

Chicago.

SECRETARY GAGE has sent to Congress a request for $20,000 to be used for improvements at the United States Marine-Hospital.

BY THE WILL of Mrs. Aurelia R. King, relict of Henry W. King, which was filed for probate, January 7, the Presbyterian Hospital receives $1000.

ABOUT 75 applicants for certificates to practice medicine or midwifery in Illinois were examined by the State Board of Health, January 9, 10, 11 and 12 at the Great Northern Hotel.

THE Commissioner of Health desires to secure reports of the Chicago Health Department for the following years: 1870-3, 1876, 1877, 1879, 1880, 1886, 1889, 1890. Address Dr. Arthur R. Reynolds, Room 2, City Hall, Chicago.

INVESTIGATION by the health department has disclosed that St. Anthony's Hospital, a private institution on Frankfort street, is being operated without a license. It was at this place that two patients died January 3 from asphyxiation by gas.

DR. CHARLES EBERLEIN, of the county asylum at Dunning, was fined $10 for contempt of court by Judge Baker, January 12, because he did not remain in court as a witness. He gave as reason that he had already been away from his duty two days, that he could not longer neglect his patients, and furthermore, that Superintendent Lange had ordered him not to appear. He was released after filing a bond for $500.

THE HEALTH DEPARTMENT states that pneumonia is reported as the cause of 161 out of the total 551 deaths recorded last week—an increase of 32 over the previous week's record and an excess of nearly 43 per cent. over that of the corresponding week last year. Never before in the history of the city has this disease been so prevalent and so fatal. The highest previous reported number of pneumonia deaths was in the week of Feb. 25, 1899. when 140 were recorded. The year 1899 was marked by a serious increase in the mortality from pneumonia. During the five years, 1894 to 1898, inclusive, the average yearly deaths from this disease numbered 2130; in 1899 there were 3438, and in 1900 there were 3389 such deaths—an average increase of 37.6 per cent. and the first twelve days of 1901 show an even higher rate of increase.

AN ANTI-SPITTING ORDINANCE, the second in the history of the city, was passed in the City Council, January 14. It is as follows: Whereas, Spitting on sidewalks, in public places and in public conveyances is detrimental to health, by reason of the danger of spreading contagious disease, and is also a public nuisance which should be abated, therefore, Be it ordained by the City Council of the city of Chicago, that no person shall spit on any public sidewalk or on the floor of any public conveyance, or on the floors of any theater, hall, assembly room or public building; that any person violating the provisions of this ordinance shall on conviction be fined in a sum of not less than $1 nor more than $5; that this ordinance shall be in effect from and after its passage and approval by the mayor.

THE SMALLPOX SITUATION is substantially unchanged. The 19 new cases discovered during the week were, without exception, persons who have never been vaccinated or at some period so remote that the vaccination had lost its protective power. Susceptibility to the contagion of smallpox differs in individuals, and the same is true as to the protection of vaccination. As a rule, a successful vaccination in infancy or early childhood, followed by a successful revaccination at 14 or 15 years of age, confers an absolute immunity from smallpox during life. In a certain number of cases, however, probably 2 per cent., the vaccinal protection is exhausted sooner and the individual is then liable to contract smallpox on exposure. There is no other known method of determining when this occurs or who these susceptibles are except by the test of re-vaccination; if this "takes" in a given individual it is certain that such individual would have "taken" smallpox or varioloid, if exposed to the contagion.

INDIANA.

ELKHART COUNTY pays $100 a year for the care of the sick in its asylum to Dr. Metius M. Eckelmann.

ST. EDWARD'S HOSPITAL, New Albany, is to be paid $625 a year for two years by order of the city council.

SIXTEEN APPLICANTS for licenses to practice medicine appeared before the State Board of Medical Registration and Examination, at Indianapolis, January 8.

DR. I. WRIGHT SHORT has been appointed surgeon of the Lake Shore and Michigan Southern Railroad at Elkhart, vice Dr. William E. Bowman, resigned.

A BILL, inspired by the spread of the "Dowie" heresy in Lake county, will be introduced in the state legislature. It is designed to protect young children from the fanaticism of their parents who may desire to have them treated by "faith-cure" methods. The bill provides that every parent shall employ a registered physician for children under the age of 16, and also provides serious penalties for negligence or violation of the law.

IOWA.

Dr. G. Allen Staples and wife, Dubuque, have returned from Europe.

Dr. Fred W. Powers, Reinbeck, has been appointed a member of the State Board of Health to succeed Dr. Joseph A. Scruggs, Keokuk, whose term has expired.

The Faculty of the medical department of the State University at Iowa City has voted to increase the length of the college term from six to nine months, the new provision to become effective September 1.

The State Board of Health, believing that the wide spread of smallpox in the state is due, in part at least, to the failure of physicians to make diagnoses and to enforce quarantine, has promulgated an order that physicians who fail to comply with the regulations will be cited to appear before the State Board of Medical Examiners and show cause why their certificates should not be revoked for incompetence or wilful violation of the rules of the board.

KENTUCKY.

Dr. Melvin H. Wheeler, Falmouth, had a paralytic seizure, January 1.

Dr. W. E. Clark, Sturgis, has been found guilty of performing criminal abortion, and has been sentenced to imprisonment for ten years.

Louisville.

Dr. William R. Blue, Louisville, has recently returned from a several months' visit to Europe, accompanied by Mrs. Blue.

The Gray Street Infirmary, Louisville, has made large additions to its building, increasing the number of rooms and adding a new operating room.

The medical department of Kentucky University has built two large lecture amphitheaters adjoining the main building, giving needed laboratory room in the main building.

The annual session of the three spring and summer medical schools began January 1 with large classes. The four years' course has not seemed to diminish the attendance at any of the colleges.

The Home for Friendless Women has elected the following medical staff: Dr. Ewing Marshall, chairman; Dr. Henry E. Tuley, secretary, and Drs. Walter F. Boggess, Philip F. Barbour, R. Lindsey Ireland, and Hugh N. Leavell. Drs. Frank C. Simpson and Louis Frank have resigned from the staff.

Dr. J. E. Cashin has been selected by the Louisville General Council special committee on sanitary affairs to make a chemical and bacteriological examination and report whether or not the water-supply of Louisville is contaminated by sewage from the Lakeland Asylum, which flows into the river via Goose Creek. The city will pay $500 for the work.

The apportionment of service at the City Hospital was made January 1: January and February, the faculty of Kentucky University Medical Department; March and April, Hospital College of Medicine; May and June, Kentucky School of Medicine, July and August, non-school members of the profession; September and October, University of Louisville, Medical Department, and November and December, Louisville Medical College.

Dr. Dudley S. Reynolds, Louisville, according to the *Louisville Monthly Journal of Med. and Surgery*, has obtained a verdict of $9,166.66 damages against the Louisville & Nashville railroad for injuries sustained from a lump of coal which fell from a coal car of an express train, as it passed the platform on which he was standing, striking him in the abdomen, just above the pubes, and inflicting injuries from which he is still suffering.

LOUISIANA.

Dr. C. Pearl Munday has been appointed assistant local surgeon of the Southern Pacific Railroad at Westlake.

Dr. Cyriaque J. Gremillion, shot and killed Dr. S. D. Beville, at Alexandria, January 7, as a result of a quarrel over a patient.

James Gibbons, an interne at the Charity Hospital, New Orleans, died January 1 from hemorrhage and shock resulting from a gunshot wound received in a fight with footpads.

The suit against Dr. Oscar Lanng, New Orleans, for $10,106 damages for "negligence and want of skill" whereby Oscar Stern lost the sight of an eye, has been decided in favor of the defendant, the court finding that the loss of sight in the eye was not proved to have resulted from any fault of Dr. Lanng.

In spite of its poor supply of funds from the city budget, the New Orleans Board of Health continues its work. With the help of a temporary 20 per cent. reduction in the official salaries and a residue of $300 from last year's funds, nine inspectors will be retained for the time being on full pay.

MASSACHUSETTS.

Lowell General Hospital is to receive $5000 from the estate of Mrs. Julia A. Simpson, of Lowell, the income from which is to be used for the maintenance of a free bed.

The Boston City Council has approved the following appropriations for the hospital department; $100,000 for a surgical out-patient department building; $120,000 for a new isolation ward and $46,500 for sundry repairs and improvements.

The new building of the Boston Medical Library, which is exceeded in size only by the College of Physicians, Philadelphia, and the New York Academy of Medicine, was dedicated January 12. It is attractive in architecture, and is finely appointed, the cost thus far being $140,000.

MICHIGAN.

Attorney-General Oren has decided that townships must erect contagious-disease hospitals.

Dr. Frederick B. Woolsey shot and seriously wounded A. L. Manly, Peamwell, during a quarrel, January 10.

Smallpox has been stamped out at Saginaw. The last patient has been discharged from the isolation hospital.

A rumor is prevalent that Dr. Jacob S. Shoemaker, of New Lothrop, who left there several months ago for South America, contracted yellow fever at Panama, and died there.

Dr. Victor C. Vaughan, Ann Arbor, has been appointed a member of the State Board of Health, vice Prof. Delos Fall, Albion, resigned, and was present at the meeting, January 11.

During the last three months of 1900, cholera morbus, typhoid fever and scarlet fever were more prevalent, and erysipelas, intermittent fever, remittent fever, pneumonia and whooping-cough less prevalent than usual in the state, as compared with the corresponding periods of the last decade.

MISSISSIPPI.

The Tom Franklin Hospital, connected with the Industrial Institute and College, Columbus, was formally opened December 20.

Dr. Thomas D. Isom, Oxford, the oldest practicing physician in Mississippi, has resigned his position as surgeon of the Illinois Central Railroad.

Dr. Joseph T. Ware, Starkville, shot and killed J. B. Hull, at Ackerman, January 1. Dr. Ware has been bound over under a bond of $2000, to await the action of the grand jury.

Dr. John E. Hunter, secretary of the state board of health, reports that county health officers complain that it is impossible to prevail upon the county boards of supervisors to make adequate provision for handling the smallpox epidemics in certain localities. A report from Holmes county shows a total of 12 deaths out of 18 cases, all of them being negroes.

MISSOURI.

The St. Joseph City Council has authorized the erection of a new isolation hospital.

Dr. David R. Porter, Kansas City, has been appointed a member of the board of pension examiners, vice Dr. Chett McDonald resigned.

Smallpox is reported in more than 100 counties in the state, and the quarantine measures thus far taken have failed to stop the spread of the disease.

Dr. James C. Smith, Agency, has been appointed second assistant at the State Hospital for the Insane, No. 2, St. Joseph, to succeed Dr. Charles B. Simcoe, who resigned December 31, to take charge of the Missouri colony for the feebleminded and epileptic at Marshall.

Dr. Edwin E. Hunter, St. Joseph, assistant city physician, has addressed a communication to the Board of Health urging that all children attending the public schools be vaccinated, as a precautionary measure, because smallpox is epidemic in several neighboring cities.

The State Board of Health has elected Dr. C. B. Elkins, Ozark, president; Dr. J. T. McClanahan, vice-president, and Dr. E. C. McElwee, secretary. Dr. S. C. James, Kansas City, introduced a resolution rescinding the action of the July meeting of the board in Kansas City in 1899, thus making it necessary for the board to recognize the diplomas of all colleges who matriculated students in 1898, and who graduated at the end of the scholastic year of 1901 and to register or license those graduates of any college having a three-year course.

A systematic crusade of compulsory vaccination was begun in Kansas City, January 10, by physicians in the employ of the city. Dr. G. O. Coffin, city physician, has divided the business part of the city into six districts, and a physician has been detained to have charge of each district. Each physician is to make a house-to-house canvass, and every person who can not show a good scar must be inoculated. Smallpox continues to gain headway in spite of the precaution, and more than 100 cases are now said to exist in the city.

AN AMENDMENT to the law regulating the practice of medicine will be introduced by Senator Rollins of St. Louis, which provides that "any person holding himself or herself out to the public as maintaining an office at any given place in this state where he or she will treat the sick, and it shall be shown that said person does not actually, and in person, do so at the place represented; or that he or she is a non-resident of this state and does not in person practice the profession of medicine at the place represented, shall be by the board adjudged guilty of unprofessional and dishonorable conduct in the meaning of the preceding section, and it shall be the duty of the State Board of Health to revoke the certificate or certificates held by any and all such persons."

MARYLAND.

DR. W. E. GRIMM, Patterson's Creek, W. Va., was arrested in Cumberland, January 3, on the charge of practicing medicine in Maryland without license and was bailed for a subsequent hearing. Dr. Grimm was the first physician to attend the smallpox patients at Pinto, Allegheny county, being constantly on the scene when another physician could not be obtained.

Baltimore.

DURING 1900, 10,700 persons died in Baltimore. This represents a mortality of 21.2 per 1000.

THE BOARD OF SUPERVISORS of City Charities has appointed Dr. Lindsay Peters resident physician of the insane department of Bayview Hospital, the city almshouse.

DR. WILLIAM RUFFNER STOVER, resident physician of the Baltimore University Hospital, has resigned to commence private practice, and Dr. William D. Bacon, assistant physician, succeeds him.

THE FLINT CLUB, named in honor of Prof. Austin Flint, held its annual banquet on the evening of January 3, Sheriff John B. Schwatka, M.D., being the presiding officer and toastmaster. The club was organized sixteen years ago by five physicians of this city.

NEBRASKA.

OMAHA has two cases of smallpox, and Lincoln one case.

DECATUR, a town of 600 inhabitants, is reported to have 416 cases of smallpox.

DR. ALEXANDER YOUNG, Arcadia, has been appointed by the governor, assistant physician at the State Hospital for the Insane, Norfolk.

THE SUPREME COURT of the state having decided adversely to the appeal of C. W. Little, a practitioner of osteopathy, he threatens now to carry the case to the United States Supreme Court for redress. His attorneys claim that by the decision the appellant has been deprived of his rights under the fourteenth amendment.

NEW JERSEY.

DR. CHARLES B. SMITH has been appointed surgeon of the Lackawanna railroad at Washington.

NOW THAT the danger of an epidemic of diphtheria is over, the health committee of the Elizabeth City Council boldly refuses to approve the bills for the expense incurred by the board of health in checking the disease.

DR. CHARLES V. BURKE, Newark, who sued Justice James J. Brylan, to recover $210, the amount agreed upon by telephone for an operation on the defendant's brother, was non-suited, the court holding that a telephone agreement was not binding.

IT IS CLAIMED that at the present time there are no funds available for the payment of current expenses of the Burlington County Hospital, Mt. Joy, in consequence of which this institution may be closed; $2000 is needed to continue the work.

THE TRADE COUNCIL of Bridgeton has decided to make a donation of $10,000 to the Bridgeton Hospital. It has been decided to raise this amount by having every member of the federation, mechanics, sales-people, and laborers, give half a day's wages toward the fund.

SCARLET FEVER is prevalent at Vineland, Swainton and Court House, Cape May County, where the schools have been closed and services at the churches have been suspended, and diphtheria at Folsom, where all churches and schools are to remain closed until all danger is over. La grippe is epidemic at Princeton, where 200 cases are reported.

THE FOLLOWING PHYSICIANS were elected by the board of trustees of the Cooper Hospital of Camden, January 8: Medical staff, Drs. William A. Davis, E. L. B. Godfrey, William R. Powell and H. Genet Taylor; surgical staff, Drs. Daniel Strock, Joseph L. Nicholson, Paul M. Mecray, and Edward A. Schellenger; ophthalmologist, Dr. William R. Powell; gynecologists, Drs. Dowling Benjamin and Joseph S. Baer; pathologist, Dr. Walter S. Bray; laryngologist, Dr. Ernest S. Ramsdell. During the past year 644 patients were admitted to the hospital; of this number 63 died and 251 were discharged, cured.

NEW YORK.

HEALTH OFFICER MOORE, of Syracuse, has issued an order for the compulsory vaccination of scholars in the public, private and parochial schools of the city.

ELMIRA has 1500 cases of grip, Binghamton 2000 cases, with 50 of typhoid, Albany 500, and cities and towns throughout the state are equally affected.

THE BEAHAN HOSPITAL has been incorporated at Canandaigua, with a capital stock of $10,000 and the following board of directors: Drs. Albert L. Beahan, Matthew R. Carson, Orlando J. Hallenbeck, John H. Jewett, Frederick E. McClellan and Harry C. Buell.

A MOVEMENT is on foot to establish, through private subscriptions, a sanatorium in the Adirondacks for working women, young married women and children suffering from consumption. A committee has been organized, of which Mrs. George F. Shrady is president. The sanatorium is to be located at Lake Kushaqua.

A NEW LUNACY BILL has been drawn up by Drs. Nelson H. Henry and John H. Girdner for presentation to the legislature, which provides that every judge to whom application is made for the examination of a supposedly insane person, shall designate a referee, and that it shall be the duty of the latter to be present at the examination conducted by the medical experts and certify as to its regularity. The bill also provides that to be eligible for the position of medical examiner in lunacy one must have had at least two years' experience in the care of the insane.

THE STATE FOREST PRESERVE BOARD and the State Board of Health have at last agreed and approved the site already recommended by the trustees for the State Hospital for the Treatment of Incipient Tuberculosis, at Raybrook, three miles southeast of Saranac village, on the side of a hill, where the hospital will be well protected from the prevailing winter winds. There are in all 525 acres, the cost of which to the state has been fixed at $7500. Most of the adjoining property already belongs to the state. There is an ample water-supply, and the place is accessible by the New York Central railroad, and by the Chateaugay branch of the Delaware and Hudson railroad. Only $1000 of the $50,000 appropriated last winter has been expended. It is intended that the hospital shall accommodate 200 patients.

Buffalo.

WORD HAS been received by Dr. Jacob S. Otto, superintendent of the sanitary exhibit of the Pan-American Exposition that all the exhibits made by the United States in the department of hygiene at the Paris Exposition will be sent to Buffalo.

AT THE annual meeting of the active members of the Sisters Hospital the following officers were elected for the ensuing year: Dr. Lawrence G. Hanley, president; Dr. Henry C. Buswell, vice-president, and Dr. Nelson W. Wilson, secretary.

THE CENSORS of the Erie County Medical Society have singled out the case of William Carpenter, who was acquitted by the grand jury of illegally practicing medicine and recommended that in consequence of this acquittal it would be advisable for the society to favor an amendment to the law relating to fines, whereby they shall be paid hereafter to the county treasurer instead of to the treasurer of the society. The censors understood that the existing arrangements concerning fines had been conducive to Carpenter's acquittal. They also asked for authority to employ detectives to continue the work of collecting evidence in the cases of illegal practitioners.

New York City.

A TUBERCULOUS PAVILION, capable of accommodating 200 patients, was opened at Bellevue Hospital, January 1. It is in charge of three graduate nurses and the house staff.

DR. HERMANN KNAPP has given to the New York Ophthalmic and Aural Institute, with which he has been long prominently connected, an adjoining plot of valuable land, with a commodious building.

AT THE annual meeting of the Beth Israel Hospital it was stated that the new building is nearly completed, and that when finished it will represent an expenditure of about $200,000. The total donations to the building fund so far amount to $40,000. During the past year 531 patients have been received into the hospital, and 282 have been refused for lack of accommodation.

THE FRENCH CONSUL-GENERAL has returned from Europe after making application to the French government for $50,000 to assist in providing more extensive accommodations in the French Hospital of this city. The changes contemplated will cost about $200,000, the hospital now having room for only 60 patients. The French government has paid a certain amount annually to the hospital, but the increase in the French population has made the proposed changes necessary.

The monthly bulletin of the State Board of Health shows that there are outbreaks of smallpox in 17 places in the State. There had been no smallpox for three months prior to the close of November, and then a traveling troupe of colored minstrels exhibited at eight places in the eastern part of the state before it was discovered that there was smallpox among them. They touched the locality in which the smallpox made its appearance recently in New York City, and smallpox followed in their trail at Albany, Schenectady and Gloversville.

Nine more cases of smallpox have developed in the city in the past week. Two of them were inmates of a lodging-house, and were the only ones there who had positively refused to allow the public vaccinators to vaccinate them. One of these, a man named Joyce, has probably been the means of spreading the disease quite extensively, for, he says that feeling ill and not knowing what ailed him, he went to Bellevue Hospital early in the morning, and was told that he had erysipelas. After receiving some medicine he was allowed to depart, and after wandering around for some time he walked across the Brooklyn bridge and into the office of the department of charities.

Grip is very prevalent, and it is the opinion of the health authorities that a severe epidemic of this disease is imminent. Reports show that since the first death from grip was reported, Nov. 10, 1900, there has been a steady weekly increase, the total number of deaths to date being 62. Including the first and very fatal epidemic of grip, which occurred in the winter of 1890-91 there have been altogether up to the present time 3796 deaths from this disease in the Borough of Manhattan. At the present time it is estimated that not less than 4 per cent. of the population is suffering from grip, and the records of the police department show that about 10 per cent. of the police force is ill, for the most part with the grip. For the week ending Jan. 6, 1900, there were 8 deaths from the grip, while the corresponding week this year showed 36 deaths from grip in Manhattan and Brooklyn. Since that date more than 25 deaths from grip have already been reported.

OHIO.

Dr. Frank S. Merwin, Youngstown, is seriously ill with typhoid fever.

Dr. Seth W. Beckwith, Toledo, ex-coroner of Lucas county, is seriously ill.

Dr. Byron C. Hendershott, New Philadelphia, has been appointed surgeon of the C. & M. railroad.

Four members of the staff of the Mahoning Valley Hospital at Youngstown, Drs. Albert L. King, Charles D. Hauser, Albert E. Warren and Charles H. Slosson, have resigned, no reason being assigned.

The State Board of Medical Examination and Registration held its annual meeting at Columbus, January 3, granted certificates to 7 applicants and elected Dr. Nathaniel R. Coleman, Columbus, president; Dr. H. E. Beebe, Sidney, vice-president; Dr. Frank Winders, Columbus, secretary, and Dr. D. Williams, Columbus, treasurer.

PENNSYLVANIA.

The trustees of the Pennsylvania Medical College at Chester, have commenced the erection of a hospital for the use of the college.

Dr. Oliver J. Bennett, Allegheny, has been appointed physician to the Western Penitentiary, vice Dr. David N. Rankin, deceased.

The sixth accounting of the estate of the late Asa Packer has been rendered and shows that the sum of $300,000 has been paid St. Luke's Hospital, Bethlehem.

A bill is to be introduced in the state legislature, providing for the appropriation of $60,000 for improvements at the Allegheny General Hospital. The improvements contemplate the rebuilding, enlarging and modernizing of the institution.

Senator Wentz and Assemblymen Barker, McGlathery and DeHaven have visited the State Hospital for the Insane and the Charity Hospital, Norristown, for the purpose of determining the needs of these institutions. The former has asked for an appropriation from the state of $90,000, and the latter for $35,000.

The results obtained by applicants at the last examination of the Pennsylvania State Board of Medical Examiners, held on December 17, 18 and 19, have been forwarded to the Secretary of Internal Affairs at Harrisburg, and shows that out of 80 applicants for license to practise medicine 41 were qualified and 39 rejected. It is said that in past years the number of failures was not much above 15 per cent., and the rate of failures reported above means a higher standard imposed upon the candidate than was formerly the case.

Philadelphia.

Dr. Henry Cattell, who for several years has been pathologist to the Pennsylvania Hospital, has resigned.

Dr. John W. Kroskey, attending surgeon to the Wills Eye Hospital, has resigned and Dr. McCluney Radcliffe has been appointed his successor.

On account of a death from smallpox in the neighborhood of Forty-first street and Girard avenue, considerable anxiety is shown lest a further spread of the disease will ensue. As a preventive measure a large number of persons in that locality have been vaccinated and the police have been called in to guard the infected house. This was the only case of the disease in the city.

The annual meeting of the Germantown Hospital was held January 12, and the following officers were elected: Elliston P. Morris, president; Thomas B. Homey. secretary; William H. Haines, treasurer; Williston P. Morris, William H. Haines. Frank J. Firth, Frances Stokes, Reed A. Williams, Jr., Alexander W. Wister, William H. Scott, Thomas B. Homer, Dr. Norton Downs, Thomas H. Shoemaker, Henry L. Davis. N. Penrose Allen. Edward H. Vance. Dr. George Woodward and James Mape Dodge, board of managers.

Owing to the existence of a number of cases of smallpox in New York the Philadelphia Board of Health is taking unusual precautions to prevent its transmission here.

About the last week of December there was a great increase in the number of cases of "colds" in this city, which was later followed by an epidemic of grippe In private practice and at the public dispensaries an increase in this disease has been noted. The weather conditions at the time of the onset of the malady did not seem to be what might be termed favorable. since the days were clear, and the temperature did not change to any marked degree. An increase in the number of cases of pneumonia has been also observed.

WASHINGTON.

Dr. Elmer E. Heg has been appointed a member of the board of health of Seattle.

Dr. Cal. M. Boswell, the pioneer physician of Colfax, was serious injured in a runaway accident recently.

Dr. Thomas E. Hoxie, Spangle, has been appointed assistant physician at the Eastern Hospital for the Insane at Medical Lake.

Dr. George W. Ingham, Olympia, has been appointed a member of the State Board of Medical Examiners.

The State Board of Medical Examiners met at Seattle, January 2 and 3, and examined 52 men and 6 women applicants for license to practice medicine in the state.

GENERAL.

Dr. Eduardo Wilde, Argentine minister at Washington, will be a delegate to the Pan-American Medical Congress at Havana.

The physicians at Havana tendered a banquet recently to Dr. Carlos Finlay in token of congratulation that his theory of the transmissibility of yellow fever by the mosquito, which he has been proclaiming for many years in the face of opposition and ridicule, has at last received scientific recognition and acceptance.

Dr. W. C. Gorgas, chief sanitary officer of Havana, states that a continuous improvement in the health of Havana is taking place. The little yellow fever they had in December was among the recently arrived Spanish immigrants. The general death-rate for December was the lowest for that month during the decade. In the report of the Marine-Hospital Service for the week ended Jan. 11, 1901, we find no deaths nor cases of yellow fever in Havana, 1 death at Cienfuegos, and 1 case at Matanzas, Cuba. Smallpox appears to be entirely absent.

The following named asst.-surgeons in the army have been ordered to San Francisco for assignment to duty with troops destined to the Philippines: John H. Allen, Washington, D. C.; H. D. Brown, Denver, Colo.; W. F. Graham, Summerville, S. C.; Lawrence Mac McEvoi, St. Louis, Mo.; F. H. Mills, Buffalo, N. Y.; Joseph Pettyjohn, Augusta, Ga.; R. J. Price, Wilmington, N. C.; J. W. Reddy, Boston, Mass.; Shannon Richmond, St. Joseph, Mo.; A. R. Schier, Burlington, Ia.; A. T. Short, Montrose, Colo.; Robert S. Spilman, Washington. D. C., and T. H. Weisenburg, Philadelphia, Pa.

DISPUTE OVER PHILIPPINE MEDICAL COLLEGE.

The decision of the Philippine Commission in the San Jose Medical College case unanimously refers the settlement of the questions involved to the courts and provides trustees who, with the assistance of the attorney-general of the Philippines, will inaugurate and prosecute the litigation. The sum of $5000 is the appropriation for the expenses of the suit. A bill has been passed carrying out the terms of the decision. It appoints five physicians as trustees, who are required to begin suit within a month in the supreme court of the Philippines to determine whether the ownership of the college is in the church or the government. The Dominican rector of St. Thomas' University and Archbishop Chappelle are required to defend the suit on the part of the church. Judge Taft's opinion says: "A case involving the construction of the Treaty of Paris and the effect upon public trusts of the transfer of sovereignty from a kingdom in which church and state are united and inseparable to one in which church and state are entirely separated is of such import that it ought to be submitted to the highest tribunal."

TO PREVENT SMALLPOX.

The spread of smallpox in the logging regions of Northern Wisconsin and Minnesota has resulted in a meeting in Duluth of members of boards of health of both states, with Secretary Bracken, of the Minnesota State Board of Health. The purpose was to decide, if possible, upon some uniform action best calculated to prevent the spread of the disease. It was decided that the only sure means of stamping out the disease is to encourage vaccination, force quarantine regulations and provide isolated hospitals at such points as may seem desirable under the circumstances. The shooting of the young woodsman at a lumber camp near Sparta, Minn., recently while trying to escape from a smallpox quarantine, had much to do with stirring the people to action. A number of the loggers who have camps on the Mesaba range were invited to attend the meeting, and they agreed to endeavor to have the men in their respective camps vaccinated. The physicians are working on some plan for allowing men in quarantine to work under special conditions. They would, under the plan proposed, be allowed to work during the quarantine period isolated from the other men in camp. The counties in which it is necessary to go to a great expense to restrict and stamp out the contagious disease will be asked to assist the towns in which the disease is being coped with.

PAN-AMERICAN MEDICAL CONGRESS.

Up to the present time—January 8—the best rates we have been able to secure for delegates attending the above congress are the regular winter tourist rates from all parts of the country to Havana and return, which from New York City is $98; Philadelphia, $94; Baltimore, $90; Washington, $88; correspondingly low rates from all other points in the United States. If my continued efforts result in lower rates, due advice will be given through THE JOURNAL. Delegates will have the option of traveling through Jacksonville, thence Florida East Coast Railway to Miami, and steamer to Havana and return; or through Jacksonville, thence Plant System to Port Tampa, and steamer to Havana and return. Steamers sail from Miami Sundays and Wednesdays at 11 p. m., arriving Havana 3 p. m. the following day. Steamers leave Port Tampa Tuesdays, Fridays and Sundays at 6.30 a. m., arriving Havana at 8 o'clock, the following morning. Inasmuch as the sessions of the congress open in Havana February 4, at 10 a. m., it seems that the route through Port Tampa, and the steamer leaving that port at 6.30 a. m., February 3, arriving Havana 8 o'clock following morning, is the best for the delegates to use. Having in mind, therefore, the comforts of the delegates, I would suggest that they arrange their trip so as to take the steamer leaving Port Tampa, 6.30 a. m., February 3. The train leaving New York at 3.25 p. m., February 1, over Pennsylvania Railroad; Philadelphia, 6.05 p. m.; Baltimore 8.27 p. m., and Washington 9:55 p. m., thence over Southern Railway through Charlotte, Columbia, Savannah and Jacksonville, which carries through sleeping cars to Port Tampa, and has dining car service, arriving Port Tampa 6. a. m., February 3, connecting with the 6.30 a. m. steamer for Havana. Through sleeping cars are also operated from Chicago and Cincinnati, through Chattanooga, Atlanta and Jacksonville, thence Plant System to Port Tampa, making the above connection. The steamer connection leaving Miami Sunday, February 3, reaches Port Tampa at 3 o'clock the following afternoon—too late for the opening session of the congress. The steamer *Seguranza* of the Ward Line leaves New York, January 30, arriving in Cuba on February 3, the day before the beginning of the congress. The new Ward Line steamer *Morro Castle*, holding 135 cabin passengers, leaves Havana on February 9, reaching New York February 11. The round trip is $70. Any one going via this route will be absent from New York twelve days. As these pages are going to press, the I. C. R.R., C. & N. W. Ry., and C. & E. I. R.R. companies consent to a reduction on rate to Havana and return; from Chicago, $86, and from other points in proportion.

FOREIGN.

SMALLPOX in Paris is gradually disappearing; there were 58 cases on January 5, compared with 105 the week previous.

PROF. V. SNEGUIREFF, of Moscow, completed thirty years of professional activity December 1. The anniversary was celebrated by his friends in many ways, among them being the founding of some scholarships and prizes in his name by funds collected by his pupils.

THE recently remodeled ophthalmic clinic at the Berlin university was reopened December 12, and bronze busts of Albrecht von Graefe and Carl Schweigger were unveiled with much ceremony.

DR. VELDE, the German physician at Pekin during the siege of the legations, has been presented with the cross of the French legion of honor, as also has his French companion, Dr. Matignon.

THE SAXON MINISTRY has issued a decree requesting physicians, boarding-house keepers and undertakers to report all cases of pulmonary tuberculosis. The decree requires also the disinfection of rooms in which persons die from that disease.

THE *Tidsskrift f. d. Norske Laegefor.* announces that a marble portrait bust is to be presented to the great Norwegian leprologist, Dr. G. Arnauer Hansen, on his 60th birthday, July 29, 1901.

A MONUMENT is to be erected by subscription to the eminent French surgeon, L. Ollier, whose death in his 76th year was recently mentioned in these columns. His international fame is chiefly due to his demonstration that experimentation on living animals is the most puissant element of progress in scientific surgery. He practically revolutionized conservative surgery by his studies of the growth and regeneration of bones and the artificial production of bone tissue by the preservation and transplantation of periosteum. Subscriptions for the monument are received by the French lay press and also by the *Revue de Chirurgie*, Paris, of which he was editor-in-chief, although he resided and practiced in Lyons.

DR. PIERRE CARL-EDOUARD POTAIN, one of the most prominent and popular physicians of Paris, died suddenly on the night of January 7, after pursuing his usual day's work and dining quietly with a few friends. He had long been professor of internal medicine and his occasional contributions to medical literature on the heart and other branches of internal medicine were accepted by authority, but his extensive practice interfered with much literary work. He was one of the founders of the *Bibliographia Medica*. His extreme kindness and gentleness won for him in the hospitals the title of "Saint Potain."

CANADA.

DR. T. M. FENWICK, Kingston, died January 3 as a result of blood poisoning engendered through paring a corn. He was graduated from Queen's University in 1866.

DRS. G. S. RYERSON and E. E. King, Toronto, succeeded in locating by the aid of a skiagraph and extracted a piece of steel chisel from a workman's eye, at the inner side of the optic nerve.

DURING the past summer a Philadelphia gentleman was taken ill while touring the Thousand Islands, and was brought to the Brockville General Hospital. He recovered, and the other day he showed his appreciation of the treatment received at the hospital by forwarding a check for $1000. The money will be used for the establishment of a nurse's home and children's ward in connection with the hospital.

THE *Bulletin Méd. de Quebec* publishes the following communication: "A little sister to the Quebec Medical Society has just been born in Portneuf county. The accouchement was long, tedious and difficult. Nine physicians were present when the child was born. It is feeble and delicate, but apparently viable. For fear of accidents it was baptized at once: 'The Medical Society of Portneuf County,' with Dr. G. Paquin as the godfather."

NATIONAL CONFERENCE ON CONSUMPTION.

The governor general and the Countess of Minto are calling a meeting in Ottawa of representative medical men and laymen from all parts of Canada for the purpose of discussing measures for limiting the ravages of consumption in the Dominion. Among other projects to be discussed is the formation of a

Dominion Association with branches in each city or province for dealing with the question; then grants by the Dominion government will also be taken up for providing sanatoria or suitable homes for the cure of persons afflicted with tuberculosis. All the provincial governments will be asked to send representatives, as well as the mayors of the larger cities, and the secretaries of the provincial boards of health. Canada is losing eight or nine thousand lives every year by consumption; and according to the general accepted estimate of statisticians, the country is paying a cash tribute of eight or nine million dollars to tuberculosis.

M'GILL'S ANNUAL LECTURE.

"A Century of Chemistry" was the title of the annual lecture at McGill, which this year was recently delivered by Dr. J. Wallace Walker. He traced the development of chemistry during the past one hundred years. At the beginning of the nineteenth century a controversy was going on as to the importance of the laws of equivalent weights. When experiment finally confirmed this law, the science took a position second to none in the world of science. Dalton's great atomic theory was also enunciated at that time and with slight modifications remains the same at the present day. The biological world had also supplied the chemist with a store of material; and the substances obtained as products of vital processes were referred to. Heating by chemistry was dealt with and one of the interesting features of the lecture was the reference to the work of a Canadian, Willson, in this line. Willson has brought on the market a new product of great value—calcium carbide. This is a gray stony-looking substance made from lime and charcoal, and possesses the remarkable property of reacting chemically with water and giving off acetylene gas, which burns with a very brilliant flame.

MEDICAL DEFENSE.

The St. Francis District Medical Association of the Eastern Townships of the Province of Quebec has recently elected the following officers: President, Dr. Brown, Richmond; vice-president, Dr. Stevenson, Coaticook; second vice-president, Dr. Rioux, Sherbrooke; secretary-treasurer, Dr. W. Russell Thomas, Lennoxville. These officers have been elected *pro tempore* by the parent association, and are to conduct the medical defense part of the association. This union is now endeavoring to gain the support of the medical profession throughout the length and breadth of Canada. Dr. Roddick, M.P., is being approached to secure a Dominion incorporation for it; and physicians will be admitted from every province at a small annual fee. The objects of this defense association are to support and protect the character and interests of medical practitioners practicing in the Dominion of Canada; to promote honorable practice, and to suppress or prosecute unauthorized practitioners; to advise or defend or assist in defending members of the union in cases where proceedings involving questions of professional principle or otherwise are brought against them; and to originate legislation likely to benefit the medical profession. A determined effort will be made to acquire legal powers for these objects.

LONDON LETTER.

AN IMPERIAL PHARMACOPEIA.

The general medical council who issue the British Pharmacopeia have taken a step which is not only of medical but political importance. They have converted the British into an imperial pharmacopeia. At one time there were three pharmacopeias in the United Kingdom which were issued by the Colleges of Physicians of London, Edinburgh and Glasgow respectively. They each constituted a legal standard, according to which, in the corresponding division of the kingdom, all preparations had to be made. Obviously considerable inconvenience arose when, say, an English pharmacist had to make up a Scotch prescription, for the preparation varied in strength in the different countries. The formation of the British Pharmacopeia by the fusion of the three local pharmacopeias was thus a great reform. The council usually issue every 10 years a new edition of the Pharmacopeias introducing new drugs and preparations of sufficient importance and rejecting others, which have fallen into desuetude. Now, many medicinal plants and other substances are considered valuable in the colonies and India, but are unknown in England. These are often equivalent to substances in the British Pharmacopeia which are very expensive or difficult to obtain in the particular locality. For example, in India there are several native vegetable oils which may be used in place of olive-oil, and there are plants which can replace others which it would be expensive to import. Hence the importance of ensuring that these substances should be prepared in a proper manner and made to conform to a uniform standard. A committee has been engaged with the assistance of the Indian and Colonial governments in procuring from all parts of the empire the necessary information from medical practitioners and scientific societies. The first result has been the publication of an Indian and Colonial addendum containing the necessary details with regard to plants or substances which in the country yielding them may be employed as stubstitutes for others in the British Pharmacopeia.

LONDON'S VITAL STATISTICS—THE LOWEST BIRTH-RATE ON RECORD.

A declining birth-rate which furnishes a chronic theme for lamentation to French politicians, appears to be becoming a phenomenon of every civilized nation. The report of the medical officer of health for London for the year 1899, which has just been issued, shows that a diminished birth-rate is a feature not only of London but of the whole of England and Wales. The number of births in London in the year 1899 was 133,585, giving a birth-rate of 29.3 per 1000, the lowest on record. From 1851 till 1860 the birth-rate was 33.6; 1861-70, 35.4; 1871-80, 35.4; 1881-90, 33.2; 1897, 30; 1898, 29.4; 1899, 29.3. Thus an almost steady decline is shown in the last 50 years. The marriage-rate during this period shows an almost parallel decline. From 20.6 in 1851-60 it has steadily fallen to 17 in 1894; it then rose slightly, reaching 18.7 in 1898, but again fell to 18.4 in 1899. The death-rate in the last half century has also shown a similar diminution. In the successive decennial periods from 1841 till 1890 the death-rates were 24.8, 23.7, 24.4, 22.5, and 20.5. In the successive years from 1891 till 1899 they were 21, 20.3, 21, 17.4, 19.5, 18.1, 17.7, 18.2, and 19.3.

NEPHRITIS WITHOUT ALBUMINURIA.

At the Clinical Society Dr. W. P. Herringham described a case of this rare condition, the first on record, in which the existence of nephritis without albuminuria in the absence of scarlatina of nephritis has been proved by necropsy. Several cases are recorded of nephritis without albuminuria following scarlatina, and the existence of albuminuria without nephritis in the absence of scarlatina has been suspected. A boy aged 4 was admitted to hospital for diarrhea and vomiting on March 29. After he was supposed to be cured he was sent to a convalescent home. The urine was examined three times and found normal. There was no history of scarlatina. From May 5 till July 14 he was in good health at the convalescent home and was under constant medical supervision. On July 14 dropsy began in the feet and spread to the legs. The urine was not albuminous. He was sent back to the hospital and for the next six weeks he looked a picture of subacute nephritis, but there was never albumin in the urine, which was exceedingly scanty. No formed elements were ever visible under the microscope. On August 29, he died. At the necropsy the viscera, including the kidneys, appeared natural. But microscopic examination of the kidneys showed cloudy swelling in a few of the convoluted tubes, and albuminous plugs in many; in some of the collecting tubes similar plugs were seen. An exudation apparently of serum or albumin was found in almost all the glomeruli.

INDENTATIONS IN THE SKULL OF THE NEWBORN.

At the Edinburgh Obstetrical Society Dr. Munro Kerr, of Glasgow, read an important paper on this subject and described a new method for the relief of the condition. The subject has received very little attention in this country, but in France it has been the subject of numerous treatises ever since Ambrose Paré first described the deformity. Indentations of the fetal skull may be spoon- or furrow-shaped. The latter are much the less serious and seldom cause much immediate trouble. Dr. Kerr, therefore, considered exclusively the spoon-shaped depressions. The injury is usually situated on one or other of the parietal or frontal bones near the anterior fontanelle. It occurs with few exceptions when there is deformity of the maternal pelvis, and generally in cases of flat rachitic pelves. The extent of the deformity need not be extreme; most commonly it is just sufficient to cause a moderate degree of obstruction to the passage of the head. In the great majority of the reported cases delivery was completed by traction either on the head by forceps or on the trunks in breech presentations. But in a small proportion labor terminated spontaneously. When deformity is present the indentation is usually caused by the head being pressed against the projecting sacral promontory. Occasionally the anterior pelvic wall, an undue prominence of the iliopectineal eminence, an osseous tumor, is the cause. Defective ossification of the fetal skull predisposes to it. In most cases the indentations disappear in a week or two and give rise to no symptoms. In some, permanent depressions result which may produce no disturbance or may give rise to minor nervous storms. Some cases terminate fatally.

with twitchings, convulsions and paralysis. In others the child is born asphyxiated and dies unless the depression is removed. Schroeder in 65 cases found that 34 per cent. of the infants were stillborn and that 15 per cent. subsequently died. In treatment air-pumps and cupping glasses have been advocated. Trephining has been successfully performed. But surgical influence is not always practicable. Dr. Kerr has treated three cases successfully by the following method. The fetal bones are very resilient and by experiments he found that artificially produced depressions can be raised by firm antero-posterior compression of the head. On the living child the indentation came out with a sound as when a dent in a felt hat is removed. In one case the seriously impaired respiration was at once relieved.

Book Notices.

TREATMENT OF FRACTURES. By Charles Locke Scudder, M.D., Surgeon to the Massachusetts General Hospital. Assisted by Frederick J. Cotton, M. D. With 585 Illustrations. Cloth; pp. 433. Price, $4.50. Philadelphia: W. B. Saunders & Co. 1900.

Although the title of this work is "The Treatment of Fractures," it will be found that the text is by no means so limited as the title, but deals in general with fractures, as the causation, pathology, diagnosis and prognosis are all discussed and often more extensively than is the treatment.

In the opening chapter on fractures of the skull are found a number of short, but valuable points on head injuries in general and on injuries to the brain complicating fractures of the bone. Under the treatment of skull fractures, he says: "In fracture of the base with pronounced symptoms, drainage of the fossa involved, whether anterior, middle or posterior, should be considered." No mention is made, however, of the symptoms which would warrant or indicate such a procedure, nor of the method of executing it nor of the probabilities of it doing any good if attempted. The danger in these cases lies in the injury done to the brain tissue and not in the fact that the fracture extends to the base of he skull.

Under the examination of injuries of the elbow, he says: "In the absence of positive signs of dislocation, subluxation and fracture, the lesion is a sprain or contusion. In the absence of positive signs of dislocation and radical subluxation a fracture will be present." The latter statement, particularly, is not only peculiar reasoning, but also incorrect. In fracture of both bones of the forearm the danger of lateral compression of the bones by the immediate application of a roller plaster cast is too great to advise this as the usual mode of treatment. In fractures of the upper third of the radius the advisability of dressing the arm in supination to prevent the loss of this motion is not mentioned.

The work is voluminously illustrated, and this fact adds materially to its value. The illustrations frequently show conditions much better than the text describes them. A chapter on "The Roentgen Ray and Its Relations to Fractures," by E. A. Codman, is excellent. It deals with the practical value of the rays in the diagnosis of fractures, the interpretation of skiagraphs and the errors of judgment into which one may be led by them. A chapter on the ambulatory treatment of fractures, which is somewhat historical in character, closes the work. While there are many good points in the work, it can not be said that the subject of fractures has been thoroughly covered, not even in treatment. The publisher's work has been unusually well done.

APPENDICITIS AND ITS SURGICAL TREATMENT: *With a Report of One Hundred and Eighty-five Cases.* By Herman Mynter, M. D. (Copenhagen), Professor of Clinical Surgery in University of Buffalo, Buffalo, N. Y. Third revised edition. Cloth. Pp. 231. Price. $2.00. Philadelphia: J. B. Lippincott Co. 1900.

This monograph was originally submitted to the University of Copenhagen in order to obtain the degree of Doctor of Medicine. It was accepted by the university in 1897, and was published in this country in 1898 as the first edition. The second edition was partly burned in the fire which destroyed the Lippincott Publishing Company in 1899. This, the third edition, has been revised and considerably enlarged by the addition of new material. The work is largely historical in character. The gradual development of modern ideas of appendicitis is traced from the earliest records. As the major portion of the work is made up of extracts from the opinions of others, it can not be criticised as coming from the author.

The author's statement, however, that he does "not consider cases of appendicitis with strictures, dilatations, coprolites, hydrops, ulcerations and the chronic and obliterating forms necessarily infectious" is not in accord with modern views of inflammation. An appendicitis not due to the action of microbes, which is the meaning of infectious here, can not be admitted.

The author's attempt to classify the cases pathologically into simple catarrhal appendicitis, ulcerative appendicitis and infectious appendicitis is open to the same objection.

Under his clinical classification he separates gangrenous appendicitis without perforation from gangrenous appendicitis with perforation. As every case of gangrenous appendicitis is certain to perforate if given time enough, there is not sufficient ground for subdivision of gangrenous cases on this basis.

Under treatment, the methods adopted by the leading men of Europe and America are considered. Much of this already has only an historical value, as opinions in regard to the treatment of appendicitis have changed so rapidly during the past few years. The author's views are decidedly in favor of early operation in acute cases and will, therefore, meet with the approval of all experienced surgeons.

Regarding chronic appendicitis, he states (page 117): "An operation is not indicated unless we feel the thickened and swollen appendix." That this is not a sound rule to follow the author himself makes very clear, for a few lines farther down he says: "I have, nevertheless, in several cases, where I was sure of feeling a hard, indurated appendix extending downward, found it in a diametrically opposite direction. What I felt was the flat tendon of the psoas minor muscle."

The work is an excellent review of the literature of the subject, and an extensive bibliography is appended. There are no illustrations.

ULCERS OF THE STOMACH AND DUODENUM AND ITS CONSEQUENCES. By Samuel Fenwick, M.D., F.R.C.P., Consulting Physician to the London Hospital, and W. Soltan Fenwick, M.D., M.R.C.P., Senior Physician to the London Temperance Hospital. Cloth; pp. 392. Price, $3.50. Philadelphia: P. Blakiston's Son & Co. 1900.

This volume is divided into four parts, the first dealing with the pathology and anatomy of gastric and duodenal ulcer, while the other three are devoted to the clinical aspects of the disease and its sequelæ. The data as regards the morbid anatomy were obtained from the results of over 1000 cases of gastric ulcer, and between 100 and 200 of ulcer of the duodenum taken exclusively from hospital records. The authors find the disease may occur either idiopathically or follow the course of some other malady. In the former case it is most common in young women, while in the latter it is not infrequently the cause of death in certain infective complaints in connection with heart and liver diseases. The book is very fully illustrated, especially in its earlier portion, and is an excellent monograph of its special subject. The illustrations are largely

Dominion Association with branches in each city or province for dealing with the question; then grants by the Dominion government will also be taken up for providing sanatoria or suitable homes for the cure of persons afflicted with tuberculosis. All the provincial governments will be asked to send representatives, as well as the mayors of the larger cities, and the secretaries of the provincial boards of health. Canada is losing eight or nine thousand lives every year by consumption; and according to the general accepted estimate of statisticians, the country is paying a cash tribute of eight or nine million dollars to tuberculosis.

M'GILL'S ANNUAL LECTURE.

"A Century of Chemistry" was the title of the annual lecture at McGill, which this year was recently delivered by Dr. J. Wallace Walker. He traced the development of chemistry during the past one hundred years. At the beginning of the nineteenth century a controversy was going on as to the importance of the laws of equivalent weights. When experiment finally confirmed this law, the science took a position second to none in the world of science. Dalton's great atomic theory was also enunciated at that time and with slight modifications remains the same at the present day. The biological world had also supplied the chemist with a store of material; and the substances obtained as products of vital processes were referred to. Heating by chemistry was dealt with and one of the interesting features of the lecture was the reference to the work of a Canadian, Willson, in this line. Willson has brought on the market a new product of great value—calcium carbide. This is a gray stony-looking substance made from lime and charcoal, and possesses the remarkable property of reacting chemically with water and giving off acetylene gas, which burns with a very brilliant flame.

MEDICAL DEFENSE.

The St. Francis District Medical Association of the Eastern Townships of the Province of Quebec has recently elected the following officers: President, Dr. Brown, Richmond; vice-president, Dr. Stevenson, Coaticook; second vice-president, Dr. Rioux, Sherbrooke; secretary-treasurer, Dr. W. Russell Thomas, Lennoxville. These officers have been elected *pro tempore* by the parent association, and are to conduct the medical defense part of the association. This union is now endeavoring to gain the support of the medical profession throughout the length and breadth of Canada. Dr. Roddick, M.P., is being approached to secure a Dominion incorporation for it; and physicians will be admitted from every province at a small annual fee. The objects of this defense association are to support and protect the character and interests of medical practitioners practicing in the Dominion of Canada; to promote honorable practice, and to suppress or prosecute unauthorized practitioners; to advise or defend or assist in defending members of the union in cases where proceedings involving questions of professional principle or otherwise are brought against them; and to originate legislation likely to benefit the medical profession. A determined effort will be made to acquire legal powers for these objects.

LONDON LETTER.

AN IMPERIAL PHARMACOPEIA.

The general medical council who issue the British Pharmacopeia have taken a step which is not only of medical but political importance. They have converted the British into an imperial pharmacopeia. At one time there were three pharmacopeias in the United Kingdom which were issued by the Colleges of Physicians of London, Edinburgh and Glasgow respectively. They each constituted a legal standard, according to which, in the corresponding division of the kingdom, all preparations had to be made. Obviously considerable inconvenience arose when, say, an English pharmacist had to make up a Scotch prescription, for the preparation varied in strength in the different countries. The formation of the British Pharmacopeia by the fusion of the three local pharmacopeias was thus a great reform. The council usually issue every 10 years a new edition of the Pharmacopeias introducing new drugs and preparations of sufficient importance and rejecting others, which have fallen into desuetude. Now, many medicinal plants and other substances are considered valuable in the colonies and India, but are unknown in England. These are often equivalent to substances in the British Pharmacopeia which are very expensive or difficult to obtain in the particular locality. For example, in India there are several native vegetable oils which may be used in place of olive-oil, and there are plants which can replace others which it would be expensive to import. Hence the importance of ensuring that these substances should be prepared in a proper manner and made to conform to a uniform standard. A committee has been engaged with the assistance of the Indian and Colonial governments in procuring from all parts of the empire the necessary information from medical practitioners and scientific societies. The first result has been the publication of an Indian and Colonial addendum containing the necessary details with regard to plants or substances which in the country yielding them may be employed as stubstitutes for others in the British Pharmacopeia.

LONDON'S VITAL STATISTICS—THE LOWEST BIRTH-RATE ON RECORD.

A declining birth-rate which furnishes a chronic theme for lamentation to French politicians, appears to be becoming a phenomenon of every civilized nation. The report of the medical officer of health for London for the year 1899, which has just been issued, shows that a diminished birth-rate is a feature not only of London but of the whole of England and Wales. The number of births in London in the year 1899 was 133,585, giving a birth-rate of 29.3 per 1000, the lowest on record. From 1851 till 1860 the birth-rate was 33.6; 1861-70, 35.4; 1871-80, 35.4; 1881-90, 33.2; 1897, 30; 1898, 29.4; 1899, 29.3. Thus an almost steady decline is shown in the last 50 years. The marriage-rate during this period shows an almost parallel decline. From 20.6 in 1851-60 it has steadily fallen to 17 in 1894; it then rose slightly, reaching 18.7 in 1898, but again fell to 18.4 in 1899. The death-rate in the last half century has also shown a similar diminution. In the successive decennial periods from 1841 till 1890 the death-rates were 24.8, 23.7, 24.4, 22.5, and 20.5. In the successive years from 1891 till 1899 they were 21, 20.3, 21, 17.4, 19.5, 18.1, 17.7, 18.2, and 19.3.

NEPHRITIS WITHOUT ALBUMINURIA.

At the Clinical Society Dr. W. P. Herringham described a case of this rare condition, the first on record, in which the existence of nephritis without albuminuria in the absence of scarlatina of nephritis has been proved by necropsy. Several cases are recorded of nephritis without albuminuria following scarlatina, and the existence of albuminuria without nephritis in the absence of scarlatina has been suspected. A boy aged 4 was admitted to hospital for diarrhea and vomiting on March 29. After he was supposed to be cured he was sent to a convalescent home. The urine was examined three times and found normal. There was no history of scarlatina. From May 5 till July 14 he was in good health at the convalescent home and was under constant medical supervision. On July 14 dropsy began in the feet and spread to the legs. The urine was not albuminous. He was sent back to the hospital and for the next six weeks he looked a picture of subacute nephritis, but there was never albumin in the urine, which was exceedingly scanty. No formed elements were ever visible under the microscope. On August 29, he died. At the necropsy the viscera, including the kidneys, appeared natural. But microscopic examination of the kidneys showed cloudy swelling in a few of the convoluted tubes, and albuminous plugs in many; in some of the collecting tubes similar plugs were seen. An exudation apparently of serum or albumin was found in almost all the glomeruli.

INDENTATIONS IN THE SKULL OF THE NEWBORN.

At the Edinburgh Obstetrical Society Dr. Munro Kerr, of Glasgow, read an important paper on this subject and described a new method for the relief of the condition. The subject has received very little attention in this country, but in France it has been the subject of numerous treatises ever since Ambrose Paré first described the deformity. Indentations of the fetal skull may be spoon- or furrow-shaped. The latter are much the less serious and seldom cause much immediate trouble. Dr. Kerr, therefore, considered exclusively the spoon-shaped depressions. The injury is usually situated on one or other of the parietal or frontal bones near the anterior fontanelle. It occurs with few exceptions when there is deformity of the maternal pelvis, and generally in cases of flat rachitic pelves. The extent of the deformity need not be extreme; most commonly it is just sufficient to cause a moderate degree of obstruction to the passage of the head. In the great majority of the reported cases delivery was completed by traction either on the head by forceps or on the trunks in breech presentations. But in a small proportion labor terminated spontaneously. When deformity is present the indentation is usually caused by the head being pressed against the projecting sacral promontory. Occasionally the anterior pelvic wall, an undue prominence of the iliopectineal eminence, an osseous tumor, is the cause. Defective ossification of the fetal skull predisposes to it. In most cases the indentations disappear in a week or two and give rise to no symptoms. In some, permanent depressions result which may produce no disturbance or may give rise to minor nervous storms. Some cases terminate fatally.

with twitchings, convulsions and paralysis. In others the child is born asphyxiated and dies unless the depression is removed. Schroeder in 65 cases found that 34 per cent. of the infants were stillborn and that 15 per cent. subsequently died. In treatment air-pumps and cupping glasses have been advocated. Trephining has been successfully performed. But surgical influence is not always practicable. Dr. Kerr has treated three cases successfully by the following method. The fetal bones are very resilient and by experiments he found that artificially produced depressions can be raised by firm antero-posterior compression of the head. On the living child the indentation came out with a sound as when a dent in a felt hat is removed. In one case the seriously impaired respiration was at once relieved.

TREATMENT OF FRACTURES. By Charles Locke Scudder, M.D., Surgeon to the Massachusetts General Hospital. Assisted by Frederick J. Cotton, M. D. With 585 Illustrations. Cloth; pp. 433. Price, $4.50. Philadelphia: W. B. Saunders & Co. 1900.

Although the title of this work is "The Treatment of Fractures," it will be found that the text is by no means so limited as the title, but deals in general with fractures, as the causation, pathology, diagnosis and prognosis are all discussed and often more extensively than is the treatment.

In the opening chapter on fractures of the skull are found a number of short, but valuable points on head injuries in general and on injuries to the brain complicating fractures of the bone. Under the treatment of skull fractures, he says: "In fracture of the base with pronounced symptoms, drainage of the fossa involved, whether anterior, middle or posterior, should be considered." No mention is made, however, of the symptoms which would warrant or indicate such a procedure, nor of the method of executing it nor of the probabilities of it doing any good if attempted. The danger in these cases lies in the injury done to the brain tissue and not in the fact that the fracture extends to the base of he skull.

Under the examination of injuries of the elbow, he says: "In the absence of positive signs of dislocation, subluxation and fracture, the lesion is a sprain or contusion. In the absence of positive signs of dislocation and radical subluxation a fracture will be present." The latter statement, particularly, is not only peculiar reasoning, but also incorrect. In fracture of both bones of the forearm the danger of lateral compression of the bones by the immediate application of a roller plaster cast is too great to advise this as the usual mode of treatment. In fractures of the upper third of the radius the advisability of dressing the arm in supination to prevent the loss of this motion is not mentioned.

The work is voluminously illustrated, and this fact adds materially to its value. The illustrations frequently show conditions much better than the text describes them. A chapter on "The Roentgen Ray and Its Relations to Fractures," by E. A. Codman, is excellent. It deals with the practical value of the rays in the diagnosis of fractures, the interpretation of skiagraphs and the errors of judgment into which one may be led by them. A chapter on the ambulatory treatment of fractures, which is somewhat historical in character, closes the work. While there are many good points in the work, it can not be said that the subject of fractures has been thoroughly covered, not even in treatment. The publisher's work has been unusually well done.

APPENDICITIS AND ITS SURGICAL TREATMENT: With a Report of One Hundred and Eighty-five Cases. By Herman Mynter, M. D. (Copenhagen), Professor of Clinical Surgery in University of Buffalo, Buffalo, N. Y. Third revised edition. Cloth. Pp. 231. Price, $2.00. Philadelphia: J. B. Lippincott Co. 1900.

This monograph was originally submitted to the University of Copenhagen in order to obtain the degree of Doctor of Medicine. It was accepted by the university in 1897, and was published in this country in 1898 as the first edition. The second edition was partly burned in the fire which destroyed the Lippincott Publishing Company in 1899. This, the third edition, has been revised and considerably enlarged by the addition of new material. The work is largely historical in character. The gradual development of modern ideas of appendicitis is traced from the earliest records. As the major portion of the work is made up of extracts from the opinions of others, it can not be criticised as coming from the author.

The author's statement, however, that he does "not consider cases of appendicitis with strictures, dilatations, coprolites, hydrops, ulcerations and the chronic and obliterating forms necessarily infectious" is not in accord with modern views of inflammation. An appendicitis not due to the action of microbes, which is the meaning of infectious here, can not be admitted.

The author's attempt to classify the cases pathologically into simple catarrhal appendicitis, ulcerative appendicitis and infectious appendicitis is open to the same objection.

Under his clinical classification he separates gangrenous appendicitis without perforation from gangrenous appendicitis with perforation. As every case of gangrenous appendicitis is certain to perforate if given time enough, there is not sufficient ground for subdivision of gangrenous cases on this basis.

Under treatment, the methods adopted by the leading men of Europe and America are considered. Much of this already has only an historical value, as opinions in regard to the treatment of appendicitis have changed so rapidly during the past few years. The author's views are decidedly in favor of early operation in acute cases and will, therefore, meet with the approval of all experienced surgeons.

Regarding chronic appendicitis, he states (page 117): "An operation is not indicated unless we feel the thickened and swollen appendix." That this is not a sound rule to follow the author himself makes very clear, for a few lines farther down he says: "I have, nevertheless, in several cases, where I was sure of feeling a hard, indurated appendix extending downward, found it in a diametrically opposite direction. What I felt was the flat tendon of the psoas minor muscle."

The work is an excellent review of the literature of the subject, and an extensive bibliography is appended. There are no illustrations.

ULCERS OF THE STOMACH AND DUODENUM AND ITS CONSEQUENCES. By Samuel Fenwick, M.D., F.R.C.P., Consulting Physician to the London Hospital, and W. Soltan Fenwick, M.D., M.R.C.P., Senior Physician to the London Temperance Hospital. Cloth; pp. 392. Price, $3.50. Philadelphia: P. Blakiston's Son & Co. 1900.

This volume is divided into four parts, the first dealing with the pathology and anatomy of gastric and duodenal ulcer, while the other three are devoted to the clinical aspects of the disease and its sequelæ. The data as regards the morbid anatomy were obtained from the results of over 1000 cases of gastric ulcer, and between 100 and 200 of ulcer of the duodenum taken exclusively from hospital records. The authors find the disease may occur either idiopathically or follow the course of some other malady. In the former case it is most common in young women, while in the latter it is not infrequently the cause of death in certain infective complaints in connection with heart and liver diseases. The book is very fully illustrated, especially in its earlier portion, and is an excellent monograph of its special subject. The illustrations are largely from photographs and are better than is sometimes the case with such reproductions. While several of the leading subjects have their own brief bibliography, quite a lengthy general bibliography is given between pages 254 and 267. The absence of reference to certain comparatively recent American papers probably ought to be expected. The book is an addition to our literature on a subject which has not been too much treated of late years.

The Tale of a Field Hospital. By Frederick Treves, Surgeon Extraordinary to H. M. the Queen. With 14 illustrations from Original Photographs. Leather. Pp. 109. Price $2.50. London, Paris, New York and Melbourne: Cassell & Co., Ltd. 1900.

Mr. Treves gives some excellent word-pictures of life in a field hospital on the desolate veldt of South Africa during the Boer war. The horror of war is seen by the army surgeon as by no one else, and this little book contains many vivid descriptions of ghastly experiences. Some of these are pathetic in the extreme, and others are amusing, though sad. The book is not written especially for medical readers, but these will be most interested in it. The author shows no mean ability as a descriptive writer, and his account of how a surgeon won the Victoria Cross is given in a way that few novelists could equal. The book is beautifully gotten up, with flexible morocco cover.

The Practice of Medicine: A Text-Book for Practitioners and Students. With Special Reference to Diagnosis and Treatment. By James Tyson, M.D., Professor of Medicine in the University of Pennsylvania and Physician to the Hospital of the University. Second edition thoroughly revised and in parts rewritten. With 127 illustrations, including colored plates. Cloth. Pp. 1222. Price, $5.50. Philadelphia: P. Blakiston's Son & Co. 1900.

This edition has given the author opportunity to bring the work up to date. The principal changes have been made in the sections on the infectious and nervous diseases; considerable attention has likewise been given to those of the circulatory system. The proofreading, however, particularly in the foreign quotations, is not always above criticism; we notice, for instance, on page 70, "anopheles claviges." New illustrations have been introduced. We have no hesitation in recommending this admirable text-book to students and practitioners.

A Handbook of the Diseases of the Eye and Their Treatment. By Henry R. Swanzy, A.M., M.B., F.R.C.S.I., Examiner in Ophthalmology to the University of Dublin. Seventh edition. With 165 Illustrations. Cloth. Pp. 607. Price, $2.50. Philadelphia: P. Blakiston's Son & Co. 1900.

This excellent text-book has been enlarged by the description of a method of employing the Roentgen rays for the detection and localization of foreign bodies within the eye. Minor alterations and improvements have been made, and several illustrations are added to the text. The different operations for cataract extraction are made plain to the beginner.

Physical Diagnosis of Diseases of the Chest. By Richard C. Cabot, M.D., Physician to Out-Patients, Massachusetts General Hospital. With 142 illustrations. Cloth. Pp. 310. Price, $2.50. New York: Wm. Wood & Co. 1900.

This volume will fill a very useful place in the student's library. It will be the more valuable for its well-selected and numerous illustrations, which serve admirably to assist the comprehension of the text.

Deaths and Obituaries.

Dr. Richard Beverly Cole, ex-president of the American Medical Association, whose death is announced as we go to press, was born Aug. 12, 1829, at Manchester, Va. He received his academic education at the Delaware Collegiate Institute, Newark, Del., and his medical studies were carried on at the medical department of Transylvania University and Jefferson Medical College, from which last institution he received his degree of M.D., in 1848. He subsequently continued his studies in Germany, France, and Great Britain. After a short residence in Philadelphia he removed to San Francisco in 1852, where he had since resided, and has been one of the most prominent members of the medical profession of the Pacific coast. He was surgeon-general of the celebrated vigilance committee of 1856, was surgeon-general of the state of California from 1868 till 1872 and again 1874 till 1876, and has held other official positions of note. He was one of the early movers in medical education on the coast, having held the chair of obstetrics and gynecology in the medical department of the University of the Pacific from 1858 till 1864, and since 1870 in the medical department of the University of California. Besides his presidency of the Association, 1895-6, he was its first vice-president in 1873, and the similar positions held by him in other societies and his honorary membership and fellowship are too many to enumerate. His specialty was surgery, and more particularly gynecology, and he held a high position among his fellow-workers in the field. We have no particulars of his latest illness, but there has passed away full of honors and years one of the most prominent figures in the medical profession of the western section of our country.

John Mason Gaston, M.D., New York University, 1848, a charter member of the Marion County Medical Society and for nearly half a century an esteemed practitioner of Indianapolis, at his home in that city, January 11, after a short illness, aged 82.

Edward Farrell, M.D., College of Physicians and Surgeons, New York, 1864, professor of surgery in the Halifax School of Medicine and president of the Nova Scotia Medical Society, at his home in Halifax, N.S., from pneumonia followed by typhoid fever, January 1, aged 57.

John F. Mahoney, M.D., Harvard University Medical School, 1887, of Chelsea, Mass., in California, aged 37. He was an esteemed member of the staff of the Rufus E. Frost General Hospital, which met January 1 and passed resolutions of respect, sorrow and sympathy.

Abram Claude, M.D., University of Maryland, 1838, for eight terms mayor of Annapolis, professor of chemistry at St. John's College, and during the Civil War a surgeon in the U. S. army, at his home in Annapolis, January 10, aged 82.

Herman Baer, M.D., Medical College of the State of South Carolina, Charleston, 1861, prominent alike as a scholar, pharmacist, physician and citizen, at his home in Charleston, January 2, from apoplexy, aged 70.

David D. Benedict, M.D., Western Reserve University, Cleveland, 1861, surgeon of the 17th Ohio Infantry in the Civil War, at his home, Norwalk, Ohio, from heart disease, January 5, aged 67.

Richard J. Linderman, M.D., Pennsylvania Medical College, Philadelphia, 1858, at one time State Senator from Bucks county, at his home in Philadelphia, January 6, aged 65 years, after a prolonged illness from heart disease.

Smith Howell Mapes, M.D., New York University, 1863, at his home in Indianapolis, January 10, after a long illness, aged 60.

Robert L. Brooks, M.D., Tulane University, New Orleans, of Calhoun, suddenly, from heart disease at Monroe, La., January 9.

S. W. Dean, M.D., University of Minnesota, an interne at the City Hospital, Minneapolis, from diphtheria, January 7, aged 25.

Edwin Boggs Johnston, M.D., Western Pennsylvania Medical College, Pittsburg, 1895, at his home in Allegheny, January 1, aged 29.

Sidney Allen Conkwright, M.D., Jefferson Medical College, Philadelphia, 1892, at his home in West Sedalia, Mo., January 8, aged 31.

John H. Clark, M.D., Starling Medical College, Columbus, Ohio, 1853, suddenly, at his home in Mechanicsburg, Ohio, January 7.

Edward H. Kress, M.D., Jefferson Medical College, Philadelphia, 1897, from typhoid fever, at his home in Johnstown, Pa., January 8, aged 27.

S. B. Bevill, M.D., Vanderbilt University, Nashville, Tenn., 1892, from gunshot wound received in a dispute, at Alexandria, La., January 7, aged 32.

Willis M. Perkins, M.D., Jefferson Medical College, Philadelphia, 1854, suddenly from heart disease, at his home in Aurelian Springs, N. C., January 2.

William Campbell Dodge, M.D., Jefferson Medical College, Philadelphia, 1864, of Adrian, Mich., from pneumonia in Chicago, January 12, aged 58.

Richard E. Christian, M.D., Vanderbilt University, Nashville, Tenn., 1886, from pneumonia, at his home in Rowlandtown, near Paducah, Ky., January 1, aged 45.

Thomas Bohannon, M.D., University of Louisville, one of the oldest and best citizens of Jefferson county, Ky., at his home near Louisville, January 7, aged 85.

D. Proctor Campbell, M.D., Cincinnati College of Medicine and Surgery, 1877, suddenly from heart failure, at his home, Green Springs, Ohio, January 7, aged 65.

Wade H. Jones, M.D., Medical College of the State of South Carolina, Charleston, 1858, at his residence in Tampa, Fla., after a long illness, January 5, aged 65.

Abijah W. Butt, M.D., Jefferson Medical College, Philadelphia, 1886, at his home in Paoli, Pa., after an illness of two weeks, from rheumatism, December 31, aged 38.

J. N. Huffaker, M.D., Southern Medical College, Atlanta, 1882, of Plainville, Ga., at the Erlanger Hospital, Chattanooga, Tenn., December 30, after an operation for tumor.

H. A. De Chesne, M.D., College of Physicians and Surgeons of Lower Canada, 1848, at his home in Oakland, Cal., from complications following operation for hernia, December 21.

James Richard Morison, M.D., Northwestern University, 1899, of Traer, Iowa, from typhoid fever at St. Luke's Hospital, where he was a member of the house staff, January 6, aged 29.

John Nutt, M.D., Rush Medical College, 1849, at San Diego, Cal., January 8, aged 78.

Joseph A. Garvin, M.D., Bellevue Hospital Medical College, 1894, at New York, January 11.

Jacob S. Herries, M.D., University of Michigan, 1878, recently, at his home in Waterloo, Iowa.

Walter L. Keirn, M.D., University of Pennsylvania, 1852, at his home in Lexington, Miss., January 5.

Edward L. Pardee, M.D., New York University, 1870, at his home in New York City, January 11, aged 58 years.

Francis Grafton Connolly, M.D., University of Maryland, 1871, at his home in Baltimore, January 10, aged 80.

Alexander Shaw Porter, M.D., a surgeon on the retired list of the Army, at Redlands, Cal., January 6, aged 33.

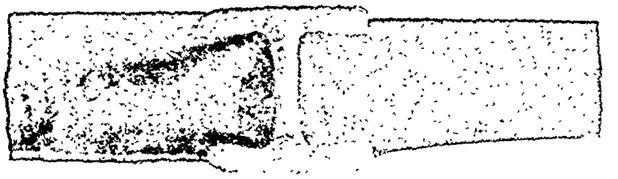
William Wood Lesley, M.D., University of Pennsylvania, 1857, at his home in Philadelphia, January 5, aged 73.

New Instrument.

A New Laparotomy Pad.

J. HENRY BARBAT, M.D.
SAN FRANCISCO.

The ordinary Kelly pad, when used for abdominal operations, allows all the solutions used in the final preparation of the abdomen to flow under the patient's back, thus keeping it in a chemical bath during the entire operation. If the Trendelenburg position is used the pad will probably overflow and the solutions will gravitate toward the patient's neck. If irrigation is necessary, part of the irrigating material will flow on the side which has no apron, and wet the table and floor. These conditions may appear of trifling importance, but those in whose charge the patient is placed after the performance of the operation will hail with delight any device which will avoid these inconveniences.



I have devised a pad which consists essentially of two Kelly pads joined back to back. The pad when in position has an apron hanging down on each side of the table. The patient's spine is in contact with the center cushion, which holds the back up from the table, and keeps it from contact with any fluids which may be in the pad.

I have further arranged the operating-table so that the center is slightly higher than the sides, thus allowing all fluids to run outward instead of under the patient, leaving the pad dry at the completion of the operation.

Miscellany.

Viability of the Plague Bacillus.—In his "Preliminary Note on the Viability of the Plague Bacillus," published as a *bulletin* of the Hygienic Laboratory of the Marine-Hospital service P.A. Surgeon M. J. Rosenau gave the result of his observations on the viability of the plague bacillus on various fabrics and substances and under varying conditions of temperature and exposure to light, presence of moisture, etc. He arrived at the conclusion that the prolonged existence of the organism was dependent upon the presence of moisture, more than upon any other one factor. He showed, for instance, that at room temperature (20 to 27 C.) the organism lived in the presence of moisture for 60 days on crash, linen, woolen or silk fabrics; that it lived 96 days in distilled water; 97 days in ordinary tap water, and for the remarkable period of 125 days upon bone dust, where the presence of moisture was assured by wetting the substance with bouillon, and carefully stoppering the container to prevent evaporation. Since the time of publication of the preliminary note, the experiments have been continued in the laboratory for a period of over a year, and have only recently been concluded. Certain food stuffs were experimented on, but the fact developed that symbiosis with saprophytic organisms was prejudicial to the prolonged life of the bacillus, and that the substances must be subjected to a preliminary sterilization, in order to favor the growth of the plague bacillus. On cheese thus prepared, it lived for 13 to 17 days; on sterilized rice for only 3 days; on dried salt beef, 3 days; on orange peel there was *no growth*: there was no growth on dried figs and raisins, though this aws subsequently proved to be due to the amount of grape or fruit sugar contained. In many of the cases of prolonged survival, however, the virulence of the organism was lost at a comparatively early period, 62 days being the longest period after which the organism was fatal to mice. Rosenau also quotes Yokote, of Tokio, as to the effect of the presence of organisms of decomposition on the existence of plague, showing in the case of the bodies of mice dead of plague that the higher the temperature, the more the decomposition and the greater the number of saprophytes, and that with lower temperatures the reverse obtained.

Prizes Offered by the Paris Academie de Medecine.—Every year the Paris Académie de Médecine distributes about $11,000 in endowed prizes, all but five open to the competition of foreigners. The total offered this year is 851,400 francs, which includes the great Audiffred prize representing an annual income of $4800 for the discovery of a sovereign remedy against tuberculosis. Manuscripts or published works are eligible for a number of the prizes, marked with an asterisk (*) in the list we give below, in which the prizes reserved for Frenchmen are omitted. Those not marked with an asterisk require the identity of the applicant to be concealed—name in separate sealed envelope—until after the awards. All competing articles must be received by February of the year in question. The Académie prize of 1000 francs or $200, for 1902, is offered for the best work on "Toxins in Pathology": for 1903, "Means of Determining the Eliminating Activity of the Kidney"; Alvarenga, 800fr., 1902 and 1905, best monograph or unpublished work on any branch of medicine; Amussat* t. 1000 fr.; 1902, for work or research which has realized or prepared the most important progress in surgical therapeutics; Baillarger*, b., 2000fr., "Treatment of Mental Diseases and Organization of Public and Private Asylums for the Insane": Barbier*, 2000fr., 1902 and 1903, for complete cure for dis-from photographs and are better than is sometimes the case with such reproductions. While several of the leading subjects have their own brief bibliography, quite a lengthy general bibliography is given between pages 254 and 267. The absence of reference to certain comparatively recent American papers probably ought to be expected. The book is an addition to our literature on a subject which has not been too much treated of late years.

The Tale of a Field Hospital. By Frederick Treves, Surgeon Extraordinary to H. M. the Queen. With 14 illustrations from Original Photographs. Leather. Pp. 109. Price $2.50. London, Paris, New York and Melbourne: Cassell & Co., Ltd. 1900.

Mr. Treves gives some excellent word-pictures of life in a field hospital on the desolate veldt of South Africa during the Boer war. The horror of war is seen by the army surgeon as by no one else, and this little book contains many vivid descriptions of ghastly experiences. Some of these are pathetic in the extreme, and others are amusing, though sad. The book is not written especially for medical readers, but these will be most interested in it. The author shows no mean ability as a descriptive writer, and his account of how a surgeon won the Victoria Cross is given in a way that few novelists could equal. The book is beautifully gotten up, with flexible morocco cover.

The Practice of Medicine: A Text-Book for Practitioners and Students, With Special Reference to Diagnosis and Treatment. By James Tyson, M.D., Professor of Medicine in the University of Pennsylvania and Physician to the Hospital of the University. Second edition thoroughly revised and in parts rewritten. With 127 illustrations, including colored plates. Cloth. Pp. 1222. Price, $5.50. Philadelphia: P. Blakiston's Son & Co. 1900.

This edition has given the author opportunity to bring the work up to date. The principal changes have been made in the sections on the infectious and nervous diseases; considerable attention has likewise been given to those of the circulatory system. The proofreading, however, particularly in the foreign quotations, is not always above criticism; we notice, for instance, on page 70, "anopheles claviges." New illustrations have been introduced. We have no hesitation in recommending this admirable text-book to students and practitioners.

A Handbook of the Diseases of the Eye and Their Treatment. By Henry R. Swanzy, A.M., M.B., F.R.C.S.I., Examiner in Ophthalmology to the University of Dublin. Seventh edition. With 165 Illustrations. Cloth. Pp. 607. Price, $2.50. Philadelphia: P. Blakiston's Son & Co. 1900.

This excellent text-book has been enlarged by the description of a method of employing the Roentgen rays for the detection and localization of foreign bodies within the eye. Minor alterations and improvements have been made, and several illustrations are added to the text. The different operations for cataract extraction are made plain to the beginner.

Physical Diagnosis of Diseases of the Chest. By Richard C. Cabot, M.D., Physician to Out-Patients, Massachusetts General Hospital. With 142 illustrations. Cloth. Pp. 310. Price, $2.50. New York: Wm. Wood & Co. 1900.

This volume will fill a very useful place in the student's library. It will be the more valuable for its well-selected and numerous illustrations, which serve admirably to assist the comprehension of the text.

Deaths and Obituaries.

Dr. Richard Beverly Cole, ex-president of the American Medical Association, whose death is announced as we go to press, was born Aug. 12, 1829, at Manchester, Va. He received his academic education at the Delaware Collegiate Institute, Newark, Del., and his medical studies were carried on at the medical department of Transylvania University and Jefferson Medical College, from which last institution he received his degree of M.D., in 1848. He subsequently continued his studies in Germany, France, and Great Britain. After a short residence in Philadelphia he removed to San Francisco in 1852, where he had since resided, and has been one of the most prominent members of the medical profession of the Pacific coast. He was surgeon-general of the celebrated vigilance committee of 1856, was surgeon-general of the state of California from 1868 till 1872 and again 1874 till 1876, and has held other official positions of note. He was one of the early movers in medical education on the coast, having held the chair of obstetrics and gynecology in the medical department of the University of the Pacific from 1858 till 1864, and since 1870 in the medical department of the University of California. Besides his presidency of the Association, 1895-6, he was its first vice-president in 1873, and the similar positions held by him in other societies and his honorary membership and fellowship are too many to enumerate. His specialty was surgery, and more particularly gynecology, and he held a high position among his fellow-workers in the field. We have no particulars of his latest illness, but there has passed away full of honors and years one of the most prominent figures in the medical profession of the western section of our country.

John Mason Gaston, M.D., New York University, 1848, a charter member of the Marion County Medical Society and for nearly half a century an esteemed practitioner of Indianapolis, at his home in that city, January 11, after a short illness, aged 82.

Edward Farrell, M.D., College of Physicians and Surgeons, New York, 1864, professor of surgery in the Halifax School of Medicine and president of the Nova Scotia Medical Society, at his home in Halifax, N.S., from pneumonia followed by typhoid fever, January 1, aged 57.

John F. Mahoney, M.D., Harvard University Medical School, 1887, of Chelsea, Mass., in California, aged 37. He was an esteemed member of the staff of the Rufus E. Frost General Hospital, which met January 1 and passed resolutions of respect, sorrow and sympathy.

Abram Claude, M.D., University of Maryland, 1838, for eight terms mayor of Annapolis, professor of chemistry at St. John's College, and during the Civil War a surgeon in the U. S. army, at his home in Annapolis, January 10, aged 82.

Herman Baer, M.D., Medical College of the State of South Carolina, Charleston, 1861, prominent alike as a scholar, pharmacist, physician and citizen, at his home in Charleston, January 2, from apoplexy, aged 70.

David D. Benedict, M.D., Western Reserve University, Cleveland, 1861, surgeon of the 17th Ohio Infantry in the Civil War, at his home, Norwalk, Ohio, from heart disease, January 5, aged 67.

Richard J. Linderman, M.D., Pennsylvania Medical College, Philadelphia, 1858, at one time State Senator from Bucks county, at his home in Philadelphia, January 6, aged 65 years, after a prolonged illness from heart disease.

Smith Howell Mapes, M.D., New York University, 1863, at his home in Indianapolis, January 10, after a long illness, aged 60.

Robert L. Brooks, M.D., Tulane University, New Orleans, of Calhoun, suddenly, from heart disease at Monroe, La., January 9.

S. W. Dean, M.D., University of Minnesota, an interne at the City Hospital, Minneapolis, from diphtheria, January 7, aged 25.

Edwin Boggs Johnston, M.D., Western Pennsylvania Medical College, Pittsburg, 1895, at his home in Allegheny, January 1, aged 29.

Sidney Allen Conkwright, M.D., Jefferson Medical College, Philadelphia, 1892, at his home in West Sedalia, Mo., January 8, aged 31.

John H. Clark, M.D., Starling Medical College, Columbus, Ohio, 1853, suddenly, at his home in Mechanicsburg, Ohio, January 7.

Edward H. Kress, M.D., Jefferson Medical College, Philadelphia, 1897, from typhoid fever, at his home in Johnstown, Pa., January 8, aged 27.

S. B. Bevill, M.D., Vanderbilt University, Nashville, Tenn., 1892, from gunshot wound received in a dispute, at Alexandria, La., January 7, aged 32.

Willis M. Perkins, M.D., Jefferson Medical College, Philadelphia, 1854, suddenly from heart disease, at his home in Aurelian Springs, N. C., January 2.

William Campbell Dodge, M.D., Jefferson Medical College, Philadelphia, 1864, of Adrian, Mich., from pneumonia in Chicago, January 12, aged 58.

Richard E. Christian, M.D., Vanderbilt University, Nashville, Tenn., 1886, from pneumonia, at his home in Rowlandtown, near Paducah, Ky., January 1, aged 45.

Thomas Bohannon, M.D., University of Louisville, one of the oldest and best citizens of Jefferson county, Ky., at his home near Louisville, January 7, aged 85.

D. Proctor Campbell, M.D., Cincinnati College of Medicine and Surgery, 1877, suddenly from heart failure, at his home, Green Springs, Ohio, January 7, aged 65.

Wade H. Jones, M.D., Medical College of the State of South Carolina, Charleston, 1858, at his residence in Tampa, Fla., after a long illness, January 5, aged 65.

Abijah W. Butt, M.D., Jefferson Medical College, Philadelphia, 1886, at his home in Paoli, Pa., after an illness of two weeks, from rheumatism, December 31, aged 38.

J. N. Huffaker, M.D., Southern Medical College, Atlanta, 1882, of Plainville, Ga., at the Erlanger Hospital, Chattanooga, Tenn., December 30, after an operation for tumor.

H. A. De Chesne, M.D., College of Physicians and Surgeons of Lower Canada, 1848, at his home in Oakland, Cal., from complications following operation for hernia, December 21.

James Richard Morison, M.D., Northwestern University, 1899, of Traer, Iowa, from typhoid fever at St. Luke's Hospital, where he was a member of the house staff, January 6, aged 29.

John Nutt, M.D., Rush Medical College, 1849, at San Diego, Cal., January 8, aged 78.

Joseph A. Garvin, M.D., Bellevue Hospital Medical College, 1894, at New York, January 11.

Jacob S. Herries, M.D., University of Michigan, 1878, recently, at his home in Waterloo, Iowa.

Walter L. Keirn, M.D., University of Pennsylvania, 1852, at his home in Lexington, Miss., January 5.

Edward L. Pardee, M.D., New York University, 1870, at his home in New York City, January 11. aged 58 years.

Francis Grafton Connolly, M.D., University of Maryland, 1871, at his home in Baltimore, January 10, aged 80.

Alexander Shaw Porter, M.D., a surgeon on the retired list of the Army, at Redlands, Cal., January 6, aged 33.

William Wood Lesley, M.D., University of Pennsylvania, 1857. at his home in Philadelphia. January 5, aged 73.

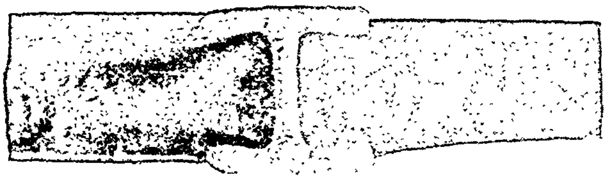
New Instrument.

A New Laparotomy Pad.

J. HENRY BARBAT, M.D.

SAN FRANCISCO.

The ordinary Kelly pad, when used for abdominal operations, allows all the solutions used in the final preparation of the abdomen to flow under the patient's back, thus keeping it in a chemical bath during the entire operation. If the Trendelenburg position is used the pad will probably overflow and the solutions will gravitate toward the patient's neck. If irrigation is necessary, part of the irrigating material will flow on the side which has no apron, and wet the table and floor. These conditions may appear of trifling importance, but those in whose charge the patient is placed after the performance of the operation will hail with delight any device which will avoid these inconveniences.



I have devised a pad which consists essentially of two Kelly pads joined back to back. The pad when in position has an apron hanging down on each side of the table. The patient's spine is in contact with the center cushion, which holds the back up from the table, and keeps it from contact with any fluids which may be in the pad.

I have further arranged the operating-table so that the center is slightly higher than the sides, thus allowing all fluids to run outward instead of under the patient, leaving the pad dry at the completion of the operation.

Miscellany.

Viability of the Plague Bacillus.—In his "Preliminary Note on the Viability of the Plague Bacillus," published as a bulletin of the Hygienic Laboratory of the Marine-Hospital service P.A. Surgeon M. J. Rosenau gave the result of his observations on the viability of the plague bacillus on various fabrics and substances and under varying conditions of temperature and exposure to light, presence of moisture, etc. He arrived at the conclusion that the prolonged existence of the organism was dependent upon the presence of moisture, more than upon any other one factor. He showed, for instance, that at room temperature (20 to 27 C.) the organism lived in the presence of moisture for 60 days on crash, linen, woolen or silk fabrics; that it lived 96 days in distilled water; 97 days in ordinary tap water, and for the remarkable period of 125 days upon bone dust, where the presence of moisture was assured by wetting the substance with bouillon, and carefully stoppering the container to prevent evaporation. Since the time of publication of the preliminary note, the experiments have been continued in the laboratory for a period of over a year, and have only recently been concluded. Certain food stuffs were experimented on, but the fact developed that symbiosis with saprophytic organisms was prejudicial to the prolonged life of the bacillus, and that the substances must be subjected to a preliminary sterilization, in order to favor the growth of the plague bacillus. On cheese thus prepared, it lived for 13 to 17 days; on sterilized rice for only 3 days; on dried salt beef, 3 days; on orange peel there was no growth: there was no growth on dried figs and raisins, though this aws subsequently proved to be due to the amount of grape or fruit sugar contained. In many of the cases of prolonged survival, however, the virulence of the organism was lost at a comparatively early period, 62 days being the longest period after which the organism was fatal to mice. Rosenau also quotes Yokote, of Tokio, as to the effect of the presence of organisms of decomposition on the existence of plague, showing in the case of the bodies of mice dead of plague that the higher the temperature, the more the decomposition and the greater the number of saprophytes, and that with lower temperatures the reverse obtained.

Prizes Offered by the Paris Academie de Medecine.—Every year the Paris Académie de Médecine distributes about $11,000 in endowed prizes, all but five open to the competition of foreigners. The total offered this year is 851,400 francs, which includes the great Audiffred prize representing an annual income of $4800 for the discovery of a sovereign remedy against tuberculosis. Manuscripts or published works are eligible for a number of the prizes, marked with an asterisk (*) in the list we give below, in which the prizes reserved for Frenchmen are omitted. Those not marked with an asterisk require the identity of the applicant to be concealed—name in separate sealed envelope—until after the awards. All competing articles must be received by February of the year in question. The Académie prize of 1000 francs or $200, for 1902, is offered for the best work on "Toxins in Pathology"; for 1903, "Means of Determining the Eliminating Activity of the Kidney"; Alvarenga, 800fr., 1902 and 1903, best monograph or unpublished work on any branch of medicine; Amussat* t. 1000 fr.; 1902, for work or research which has realized or prepared the most important progress in surgical therapeutics; Baillarger*, b., 2000fr., "Treatment of Mental Diseases and Organization of Public and Private Asylums for the Insane"; Barbier*, 2000fr., 1902 and 1903, for complete cure for dis-cases now considered incurable, such as cancer, epilepsy, scrofulas, typhus or cholera morbus, etc.; Boullard*, b. 1200fr., 1902, for best work or best curative results in mental diseases; Bourceret*, 1200fr., 1902 and 1903, best work or research on circulation of the blood; Dupierris*, b. 24000fr., 1902, for best work on "Anesthesia or Diseases of the Urinary Passages"; Capuron, 1000fr., 1902, "Relations Between Fibrous Tumors of the Uterus and Pregnancy"; Chevillon*, 1500fr., 1902 and 1903, "Treatment of Cancerous Affections"; Civrieux, 800fr., 1902 and 1903, "Various Forms of Dementia"; Clarens*, 400fr., 1902 and 1903, for best work on hygiene; Daudet, 1000fr., 1902 and 1903, for best work on so-called incurable diseases, especially tumors; Desportes*, 1300fr., 1902 and 1903, for best work on "Practical Medical Therapeutics"; Falret b. 700fr., 1902, "Somnambulisms"; E. Godard*, 1000fr., 1902 and 1903, for best work on "Internal Pathology"; Herpin, of Metz, qd., 1200fr., 1902, "Abortive Treatment of Tetanus"; Herpin, of Geneva*, 3000 fr., 1902 and 1903, for best work on epilepsy and nervous diseases; Laborie*, 5000fr., 1902 and 1903, for the work that has "Notably Advanced the Science of Surgery," awarded in 1900 to Quenu and Hartmann's book on the "Surgery of the Rectum"; Larrey*, 500fr., 1902 and 1903, best work on medical statistics; Lefèvre t., 1800fr., 1902, "Melancholia"; Lorquet*, 300fr., 1902 and 1903, "Mental Diseases"; Meynot*, 2600fr., 1902 and 1903, "Diseases of the Ear"; Nativelle*, 300fr., 1902 and 1903, for best work on the extraction of the definite principle of a medicinal substance never before isolated; Orfila, b. 4000fr., 1902, "Alkaloids of Belladonna, Hyoscyamus and Datura, considered each from the point of view of Pathology, Therapeutics, Legal Medicine and Pathologic Anatomy"; Portal, 600fr., 1902 and 1903, "Experimental Study of Inoculation and Contagion of Cancer"; Pourat, 700fr., "Study of the Destination of Albuminoid Foods"; Ricord*, b. 600fr., 1903, for best work that has appeared in two years on venereal diseases; Saintlager*, 1500fr., to be awarded to the first person who produces a tumor of the thyroid in animals by administration of substances extracted from the water or soil of places where goiter is endemic; Saintour*, b. 440fr., 1902, for best work in any branch of medicine; Stanski*, b. 1400fr., 1902, for the person who best demonstrates the existence or non-existence of miasmatic contagion by infection or contagion at a distance. If no work fulfills these conditions the prize may be awarded for the best work on any question relating to contagion of inoculable diseases. Vernois* offers 700fr., "Hygiene"; Itard*, t. 2400fr. for best book on practical medicine or applied therapeutics, published at least two years; Lefort*; qq. 300 fr., 1903, for best original research on mineral and drinking waters; Tremblay*, qq., 7200 fr., 1903, for best work on "Diseases of the Urinary Passages, Especially Affections of the Prostate and Catarrh of the Bladder." All the above are annual prizes except those marked b., biennial; t., triennial; qd., quadriennial; qq., quinquennial.

Representation in the American Medical Association.—The Association is the second largest body of medical men in the world, numbering about 10,000 and rapidly increasing. It was organized 53 years ago, when the population of the United States was less than 20,000,000 and when there were probably not more than 40 medical societies of all kinds in the country. The founders recognized the necessity of limiting the number of those who should manage its affairs, and therefore limited the number of those who should have a right to vote. Even at that time the probability was realized that the number might soon be too large to give each one a right to a voice in the management of the affairs of the association, and so the delegate system was adopted. The plan upon which it was organized is the plan upon which the Association is working to-day, with a few minor modifications. It is a delegate body and all the business appertaining thereto is managed by delegates who are supposed to be elected by affiliated societies. These have a right to vote, and only these. The plan is an ideal one. It provides for a democratic form of representation looking to a limited number of representatives who shall act for the whole. It is the adoption of the general plan of the government of our country, by which delegates are elected to represent the many and to meet in congress to legislate for all. But every ten years a reapportionment is made by the government for the purpose of equalizing representation without increasing the size of the working body—the house of representatives. The American Medical Association, however, has made no reapportionment. The delegates are elected on the same basis now as in 1846; that is, one delegate for every ten members, every society being entitled to elect delegates in this proportion. As above stated, in 1847 there were less than 40 medical societies in the country; today there are nearly 1300. The number of delegates to the American Medical Association is not based on the number of members in that body, but on the number of members of the affiliated organization sending delegates. Thus one society may have 100 members, not ten of whom belong to the national body, and yet it is entitled to send ten delegates. One person may belong to several societies and be counted several times. Again, one State, Illinois, according to the list of affiliated societies printed in The Journal A. M. A. last spring, has 96 affiliated county societies, and as one of these has nearly 1000 members it may be presumed that the combined membership of these bodies in this one state, including the state society, represent at least 4000, entitling the state to send 400 delegates. It can readily be seen, therefore, that the number of delegates from the country at large necessarily makes a body too unwieldy for any deliberative legislative work. However, it is not necessary to present these figures in order to demonstrate that the number of delegates is too large, as this is quite evident at each annual meeting and is becoming more plain each year as the number in attendance increases. Under the present ratio of apportionment practically all who desire can receive a delegate certificate. It seems strange that in all these years, with the rapid increase in the number of physicians and in the number of societies in the country, not to mention the increase in population and in territory, no change has been made in this apportionment. If important questions are to be acted on deliberatively the body which acts on them must not be an unwieldy mass but must be composed of a limited number, elected in such a way as to fairly represent the profession in all parts of the country. It would seem desirable for the American Medical Association to consider whether the time has not come for a radical change in the basis of representation to its working body. The change must be radical now, for the reason that it has been delayed so long. If a change had been made each ten years, as is done in Congress, it would not have been considered radical at any time. Now it must be, if the result is to be a deliberative body that can act in a deliberate manner on the vital questions that must come before the Association.—*N. Y. State Jour. of Medicine*, January.

Societies.

COMING MEETINGS.

Pan-American Medical Congress, Havana, Cuba, Feb. 4, 1901.

Tri-State Medical Association of the Carolinas and Virginia, Richmond, Va., Feb. 26, 1901.

The Associated Health Authorities and Sanitarians of Pennsylvania, Harrisburg, Feb. 6-7, 1901.

The Etowah County (Ala.) Medical Society met at Gadsden, January 2, for its annual session, and elected Dr. John P. Ralls, of that place, president.

The Jacksonville (Ill.) Medical Club, on December 22, elected Dr. Henry C. Campbell, president; Dr. Albyn L. Adams, vice-president; Dr. David W. Reid, secretary.

The New Britain (Conn.) Medical Society met January 2 and elected Dr. George J. Holmes, president; Dr. Harris L. Paige, vice-president, and Dr. Joseph B. Brocksieper, secretary and treasurer.

The Yakima County (Wash.) Medical Society was organized in North Yakima, December 28, with Dr. Thomas B. Gunn, president, and Dr. David Rosser, secretary pro tem, both of North Yakima.

The Arizona Academy of Medicine met at Phoenix, December 31, and elected Dr. J. Capsely McIntyre, president; Dr.

Ancil Martin, vice-president, and Dr. Payne Palmer, secretary and treasurer, all of Phoenix.

The Manhattan Dermatological Society, of New York City, has been organized with the following officers: Dr. William S. Gottheil, president; Dr. Ludwig Weiss, vice-president, and Dr. Jacob Sobel, secretary.

The Hancock County (Ind.) Medical Society met January 1, at Greenfield, and elected Dr. James W. Larimore, Greenfield, president; Dr. E. R. Sisson, Maxwell, vice-president, and Dr. Milo Gibbs, Greenfield, secretary and treasurer.

The Wapello County (Iowa) Medical Society met at Ottumwa, January 2, and elected the following officers: Dr. Lewis J. Baker, president; Dr. Frank W. Mills, vice-president, and Dr. Charles R. Russell, secretary and treasurer, all of Ottumwa.

The Orange (N. J.) Practitioners' Society held it first annual meeting January 4, at which the following officers were elected: Dr. Edgar Calvin Seibert, president; Dr. J. Minor Maghee, vice-president, and Dr. Stephen G. Lee, secretary and treasurer.

The Academy of Medicine, of Los Angeles, Cal., at its meeting December 28, elected the following officers: Dr. Benjamin F. Church, president; Dr. Charles W. Bryson, vice-president; Dr. William W. Apple, secretary, and Dr. Charles E. Bacon, treasurer.

The Fayette County (Pa.) Medical Society has elected Dr. Robert S. McKee, New Haven, president; Dr. Levi S. Gaddis, Uniontown, secretary and treasurer; Dr. John D. Sturgeon, Uniontown, assistant secretary, and Dr. Jacob S. Hackney, Uniontown, censor.

The Madison County (Ind.) Medical Society met at Anderson and elected Dr. J. W. Coverston, Frankton, president; Dr. Edward W. Chittenden, Anderson, vice-president; Dr. Oscar E. McWilliams, Anderson, secretary, and Dr. William W. Kneale, Anderson, treasurer.

The Weber County (Utah) Medical Society met December 27 and elected the following officers: Dr. Edward M. Conroy, president; Dr. Chester E. Coulter, vice-president; Dr. James M. Harris, treasurer; Dr. Hayward Powers, librarian; and Dr. Harry B. Forbes, secretary, all of Ogden.

The Belmont County (Ohio) Medical Society, at its recent meeting at Bellaire, elected Dr. John A. Heinlein, Bridgeport, president; Dr. Samuel L. West, St. Clairsville, vice-president; Dr. Alfred C. Beetham, Bellaire, treasurer, and Dr. James S. McClellan, Bellaire, secretary.

The St. Louis Medical Society held its annual meeting December 29 and elected Dr. Lewis E. Newman, president; Dr. William W. Graves, vice-president; Dr. Clifton R. Dudley, recording secretary; Dr. Alonzo R. Kieffer, treasurer, and Dr. William B. Shields, corresponding secretary.

The Hancock County (Ohio) Medical Society held its annual meeting at Findlay, January 3, at which Dr. John M. Firmin was elected president; Dr. Norman L. McLachlan, vice-president; Dr. Don C. Hughes, secretary-treasurer, and Dr. Theron S. Wilson, assistant secretary, all of Findlay.

The Northwestern (Iowa) Medical Association met at Sac City, December 27, and elected the following officers: Dr. Bernard C. Kelly, Carroll, president; Dr. M. L. Le Duc, Breda, vice-president; Dr. Daniel W. Wheelwright, Wall Lake, secretary, and Dr. Daniel J. Townsend, Lohrville, treasurer.

The York County (Pa.) Medical Society held its annual meeting January 3, and elected Dr. Roland Jessop, York, president; Drs. Nathan C. Wallace, Dover, and Jerry C. Murphey, York Haven, vice-presidents; Dr. Ralph A. Harding, York, secretary, and Dr. J. Ferdinand Klinedinst, York, treasurer.

The Jasper County (Mo.) Medical Society held its annual election of officers at Joplin, January 2, with the following result: Dr. D. V. Wale, Carthage, president; Dr. L. C. Chenoweth, Webb City, vice-president; Dr. Elizabeth L. Hull, Carthage, secretary, and Dr. Luther I. Matthews, Joplin, treasurer.

The Altoona (Pa.) Academy of Medicine and Surgery, at its meeting January 2, elected Dr. J. Herbert Hogue, president; Drs. Frederick H. Bloomhardt and Henry H. Brotherlin, vice-presidents; Dr. J. Wesley Rowe, recording secretary; Dr. Mary Irvin Thompson, corresponding secretary, and Dr. Joseph U. Blose, treasurer.

The Lancaster City and County (Pa.) Medical Society, on January 3, elected the following officers: Dr. John J. Newpher, Mt. Joy, president; Drs. Milton U. Gerhard, Lancaster, and Edwin J. Miller, Intercourse, vice-presidents; Dr. Park P. Breneman, Lancaster, secretary; Dr. George R. Rohrer, Lancaster, treasurer, and Dr. Jacob R. Lehman, Mountville, corresponding secretary.

The Medical Science Club of Topeka (Kas.) was organized January 5, its object being the advancement of medical knowledge among its members, the investigation and study of all subjects pertaining to the science of medicine, and the furtherance of fraternal unity in the profession. The following officers were elected: Dr. William E. McVey, president; Dr. O. Portis Davis, vice-president, and Dr. Corban E. Judd, secretary and treasurer.

The Toledo Medical Association met Jan. 11 and elected Dr. William H. Fisher for president; Dr. John North, vice-president; Dr. Charles P. Wagar, recording secretary; Dr. A. C. Schnetzler, corresponding secretary; Dr. F. E. Klauser, treasurer; Drs. J. C. Reinhart, A. C. Schnetzler, F. Jacobi, A. F. McVety and J. D. Ely, executive committee; Drs. H. A. Root, W. V. Anderson, K. M. Bainbridge, H. E. Smead and F. A. Leslie, examining committee; Dr. H. Hathaway, member of library board for 5 years; Drs. W. C. Chapman, H. Hathaway and W. D. Stewart, legislative and sanitary committee.

The Columbia (S. C.) Medical Society met January 1, the vice-president, Dr. William Weston, in the chair. Dr. Benjamin W. Taylor, the senior member of the society, read a paper on "Appendicitis," after which Dr. James Woods, Babcock, superintendent of the State Hospital for the Insane, presented a handsome silver pitcher, suitably engraved, to Dr. Taylor on behalf of the society. In closing his remarks, Dr. Babcock said: "He has been our guide and friend in many of those trying ordeals which all physicians are called on to pass through. While we admit with Stevenson that gratitude is a lame sentiment and that thanks when expressed are often more embarrassing than welcome, yet, as members of the Columbia Medical Society, I ask you one and all to rise while I present this token of our fealty, love and admiration." Dr. Taylor made an appropriate and feeling response, and the society then adjourned and participated in the banquet prepared for the occasion.

New York Neurological Society.

Stated Meeting, Dec. 4, 1900.

President Dr. Frederick Peterson, in the chair.

TERMINAL CONDITION IN A CASE OF DIPLEGIA.

Dr. William M. Leszynsky presented a man, 21 years of age, in whom the chief feature of interest was a trembling of the hands, existing as long as he could remember. The trembling, which was growing worse, had always been more marked on the left side. No disturbance of sensibility could be detected. There was excellent muscular development on the left side and a spinal curvature, probably arising from the use of one side more than the other. There were no signs of atrophy. There was some asymmetry of the cranium. There was no disturbance of vision, but concentric contraction of the visual field. There was no nystagmus, and the pupils and fundi were normal. There was a positive tremor when at rest, increased on motion. The elbow-jerk was elicited only on the right side. Both knee-jerks were exaggerated. Ankle clonus had been demonstrated on both sides, though much more marked on the left. The man had probably recovered from a paralysis that he had had at one time, and was now suffering from a terminal condition of an infantile palsy. Undoubtedly there was a good deal of functional disturbance added to the organic trouble.

Dr. M. Allen Starr thought the case was an athetosis on the left side, and that probably the same lesion, to a minor degree, was present on the opposite side. It was apparently a post-diplegic condition.

Dr. E. D. Fisher also looked upon the case as one of cerebral diplegia most marked on the left side, and with the athetoid movements often seen in such cases. This extreme muscular development seemed to him not at all uncommon in this class of cases.

Dr. B. Sachs said that there could be no doubt that the left side was the center of disturbance, and it was also probable that a part of the tremor was functional. The condition of the muscles in the scapular region seemed to him fully accounted for by the spinal curvature present.

Dr. F. Peterson agreed with the diagnosis of post-paralytic athetoid form of movement. Where the paralysis was small he thought these finer movements were more apt to be present.

TWO CASES OF SPINAL TUMOR, WITH OPERATION.

Dr. M. Allen Starr said that five years ago he had been able to collect 145 cases of spinal tumor, in 22 of which operation had been undertaken. In the cases forming the subject of the paper pain had been very prominent, and this, together with the symptoms of pressure on the cord had allowed of the diagnosis being made. Two cases were reported in full, the first being operated on Oct. 22. On dividing the dura an extremely edematous state of the pia was observed, with one white plaque lying upon it. The cord was smaller and whiter than normal, and was not pulsating. No tumor was found. Three days later the wound was enlarged upward and the dura found to pulsate freely at the upper level, but not lower down. A tumor, 1⅛ inches in length, lay upon the cord. It was oval, had a distinct capsule, and was removed en masse without difficulty. Subsequent examination showed it to be a fibroma. The cord had been reduced to about one-half of its diameter beneath the tumor. No attempt was made by Nature to heal the first operation-wound, and in spite of great care an extensive bed-sore developed over the hip. In the second week after operation the constricted feeling became less marked. The operation-wound healed very slowly. In the fourth week after the operation she had constant fever, probably because of the extensive bed-sores. The spinal incision healed about this time, but she died a few days later. The autopsy showed a softened condition of the cord opposite the exit of the second dorsal nerve from the dura, and the fifth and fourth dorsal nerves could be traced into this area. Owing to the rudimentary condition of the spine of the third cervical vertebra an error of one vertebra had been made in the count at the time of operation. The case seemed to emphasize the fact that there should be no delay in operating for spinal tumor after the diagnosis had been reached. In this case the delay had arisen from an effort to try the effect of antisyphilitic treatment, the husband being known to be syphilitic. Gumma of the spinal cord is quite rare, only 26 such cases having been found in a series of 400 cases. The tumor had been found about two inches higher than had been anticipated. Reed's table had been used as a guide at the first operation, but according to Bruns the operation should be done two segments above the upper limit of pain. This advice was nearer the truth in the present case. The level of the pain was about eight inches lower than the level of the tumor; hence in operating for spinal tumor the level of the cord should be exposed at least four inches higher than the level of the spinal nerve in which pain is found. The operation was done by Dr. McCosh.

The second case was also operated on by the same surgeon. He removed the spines and arches of the second, third and fourth lumbar vertebræ. Dissection showed a tumor involving both the soft and hard tissues of this region. The spines and arches had been eroded by the tumor, which subsequently proved to be an endothelioma. This tumor had invaded the spinal canal and produced pressure on the dura. The patient was in a critical condition for two days after operation, but since then had improved rapidly, and had had no pain since the operation. A considerable degree of atrophy had developed in both peronei. The wound had healed perfectly and there was no evidence of recurrence. It was reasonable to hope for recovery unless there should be speedy recurrence. Out of 145 cases of spinal tumor that he had collected, the history had been fairly clear in 122. Of 76 cases an operation should have been feasible, and according to the pathological report in 75 per cent. the tumors could have been removed.

Dr. A. J. McCosh said that he had found spinal surgery much more satisfactory than brain surgery; certainly the localization of the lesions had been more satisfactory. It was difficult to say, however, that a lesion is situated at any one segment of the spinal cord, but as a portion of the cord equal to three or four vertebræ must be exposed a slight error in localization is not of great importance. He had had recently a case presenting symptoms almost exactly like those of the first case reported in the paper. The line of anesthesia had been almost the same, but there had been no paralysis of the arms. The autopsy showed a crushing injury of the cord between the fourth and sixth cervical vertebræ. The ordinary rules laid down had indicated a lesion much lower down, and he had in this way been misled at the operation. He had not found laminectomy a very serious operation as a rule, most of the patients having exhibited comparatively little shock; hence, one should not hesitate in advising the operation when the diagnosis was sufficiently clear. He agreed thoroughly with what Dr. Starr had said about the inadvisability of delaying the operation for weeks in order to give antisyphilitic treatment a trial. He had met with a number of cases in which he believed the fatal result was attributable to such delay. When bed-sores were already present the case was practically hopeless, the patient almost invariably dying from sepsis. It was well to remember that tumors of the cord are usually found higher up than the estimated level. By beginning above and working downward, it seemed to him that the healing process would be favored. He was not of the opinion that there was any good ground for believing that the operation of laminectomy so weakens the spine as to lead to disability. Mention was made of one of his cases in which a man was engaged at an occupation requiring the frequent lifting of heavy weights, yet he had felt no inconvenience as a result of the operation on his spinal column.

Dr. Pearce Bailey reported the case of a man, 41 years of age, who had been treated for some time previously for a variety of troubles. When seen in May he had stated that about fifteen months previously he had begun to have intense pain on the inner side of the left thigh. There had been an interval of a few months in which this pain had almost subsided. There was slight atrophy in the left leg; the left knee-jerk was absent; there was very slight anesthesia. The case was diagnosticated as one of tumor of the cauda equina. Dr. McCosh had operated upon him on May 22. He had removed the last dorsal and the first and second lumbar vertebræ, and had exposed what had looked at first like a blood-clot, but microscopical examination had proved this to be a round-celled sarcoma. Although it was probable that all of this sarcoma had not been removed, the man had done extremely well all these months, was free from pain and had resumed his occupation.

ANALYSIS OF SYMPTOMS OBSERVED IN TUBERCULAR MENINGITIS AT THE BABIES' HOSPITAL.

Dr. C. A. Herter made an analysis of 24 cases of tubercular meningitis, and in 15 of these there were autopsies. In these 15 cases, 6 were at the age of eight months; 7 were one year old or under. In 9 cases of tubercular meningitis without autopsy, 6 were five months old. These figures showed that the disease was not so rare in the first year of life as had been supposed by some writers. Nineteen of the cases had run their course in less than one month. The fontanelle had been markedly distended in 7 of the 24 cases, and in 3 there had been a marked excess of fluid found at autopsy. In one case the fontanelle had been depressed—a case sick for four or five months. In six cases there had been a delay in the closure of the fontanelle. Vomiting had been noted in 19 of the 24 cases, and had been the first symptom in 14 cases. In five in which there was vomiting, the autopsy showed nothing different from the cases that had presented vomiting. In 11 cases there had been marked constipation. In cases coming to autopsy there had also been tuberculous lesions in the intestine. In several of the cases there were tubercular ulcers of the colon, and yet constipation instead of diarrhea had been present. The pupils were unequal in 12 of the 24 cases, and dilated in the others. The pupils were contracted in only two cases. Nystagmus was observed in four cases, and strabismus in ten cases. In the cases showing strabismus there were marked lesions at the base and in the interpeduncular space. There were general convulsions in 50 per cent. There was no case which did not present either rigidity or convulsions. In cases without meningitis but with tubercles in the brain, convulsions were not so common. Paralysis was noted in 10 of the 24 cases, and was monoplegic in a number. The variability of these palsies was a rather notable feature. In the cases without meningitis but with tubercles in the brain, no palsies or paralyses were noted. The tache cérébrale was noted in 7 cases, and flushing of the face in 10 cases. All the fatal cases had presented stupor or coma, or more or less irregularity of respiration, while these had not been observed in any of the cases with tubercles, but without meningitis. Hyperesthesia had been noted in only one case, and in only one had there been a well-developed cephalic cry. Retraction of the abdomen had been noted to a greater or less degree in 15 of the cases, but not at all in the other cases. The fever had not been high in the uncomplicated cases, and the pulse had shown nothing distinctive. In the cases without meningitis marked opisthotonos and convulsions had been the rule, and early vomiting had been much less frequent than where meningitis was present. Only two or three of the cases had presented solitary tubercles. In all of the autopsy cases the cerebral tuberculosis had been clearly secondary. The intestine was the seat of tuberculous lesions in 11 of the 12 cases in which the intestine was examined. The knee-jerks were increased in a large proportion of cases, and absent in only two. An interesting feature was that at times the knee-jerks would be alternately exaggerated and absent.

California Academy of Medicine.

Monthly Meeting, Dec. 18, 1900.

President Dr. D. O. Montgomery in the chair.

TUBERCULAR JOINTS.

DR. H. M. SHERMAN presented a case which had already been before the Academy. At that time he showed the result of an excision of the elbow, and called attention to the hip of the same side, which was swollen and tender in places; on one day the boy could walk well, and on another he would be lame. Some time before there had been a fluctuant swelling in the upper part of the thigh, and, for the sake of exploration this had been emptied by the aspirator, the contents being clinically tuberculous pus. This particular abscess had not refilled, and its emptying had caused entire disappearance of the symptoms which accompanied it. The symptoms noted at the time the case was in the Academy developed later, and were not the same as those of the abscess. The case very strongly suggested hip-joint tuberculosis, but an analysis of the symptoms prevented that diagnosis. After being shown at the Academy the boy got steadily worse, and the general swelling softened in one part above the trochanter, and fluctuation was palpable. The opening of this fluctuant place let out tubercular pus, and the cavity led down to the rim of the acetabulum, at its upper part, where was found a sequestrum, wedge-shaped, and quite free. It was removed; its bed was scraped out, and the cavity joint, which was already open into the abscess, was thoroughly washed out. The femoral head appeared normal. The wound was closed with temporary drainage and healed very kindly. Very shortly it broke down again and formed a sinus leading into the joint and always discharging. A formal excision of the hip was done and considerable of the ilium, the seat of a tuberculosis that had spread from the site of the sequestrum, was removed. The wound was packed with serile gauze, and made to heal from the bottom. By this time the elbow had again broken down, and it was again laid open and thoroughly scraped out and washed. It too was packed and healed. Since these operations the general health of the patient has been perfect and there had been much increase in weight. The elbow is especially satisfactory; flexion is efficient and of normal range; extension is not so strong; the hand can be put on the head, and is commonly used for all ordinary purposes. The use of the hip has not yet begun.

In this case it seems likely that the elbow was the primary lesion, and the hip secondary to it, for no other lesion, skeletal, glandular or visceral, can now be found; and his health and general development do not suggest the idea of a latent lesion, though they may not be absolutely incompatible with the existence of one. Section of the femoral head after removal showed that the tuberculosis was invading its upper half, that which had been in contact with the sequestrum in the lip of the acetabulum.

HYDROCELE.

DR. DUDLEY TAIT exhibited a patient 79 years of age, on whom he had operated three months ago, and read a paper on the treatment of hydroceles. He said that the essentials of a radical cure are that it shall be devoid of danger and pain, prevent recurrences, and finally that it shall permit the patient to resume his ordinary business in the shortest possible time. He condemned the treatment by the injection of irritating fluids for the purpose of producing adhesive inflammation between the layers of the serosa, also Volkmann's operation of incision, followed by suture of the edges of the serosa to the skin, with or without drainage, as being very uncertain in their results. In twelve of his cases operated by the latter method, he noted relapse in two, and called attention to the fact that German authors acknowledged 12 to 15 per cent. of recurrences after Volkmann's operation. Partial excision of the parietal tunica vaginalis, by which an incision is made down to the fibroserous layer; the tumor, still unopened, is then dissected by means of gauze, or the finger, until the mass is free from the cellular layer, especially posteriorly. A long incision is then made in the sac, from which the liquid escapes. The tunica is then turned inside out, placing the endothelial surface outward and securing the cut edges of the serosa as high as possible around the cord by means of two or three catgut sutures. The testicle is then replaced in its normal position. It is covered by the skin, dartos and cellular tissue. Suture of the skin without drainage completes the operation, which requires generally from five to ten minutes.

He did not claim, however, the slightest priority for this measure, in as much as Longuet published a description recently, and stated having treated 22 cases by this plan, the majority as early as 1898. Among the objections made to the method of inverting the tunica vaginalis, were the risk of injuring the cord, fixation of, and subsequent atrophy of, the testicle, and the possibility of relapse. All these points have been refuted by the experience of Longuet, who had not found a single instance of recurrence in his list of 22 cases. Dr. Tait's personal observations comprised two cases, one of which was the patient exhibited at this meeting, in which an examination of the patient at this time (three months after operation), showed the scrotal tissues freely movable over the surface of the testes. The inverted tunica undergoes atrophy.

DR. CHARLES P. THOMAS, Spokane, said that he could not quite see the advantage of the operation described by Dr. Tait over the one he usually performed, which is that of excising the tunica vaginalis. He believed that every clean surgeon is convinced that the open method is the right one. The diagnosis is not always easy, but is always cleared up by the incision method, which he thought was the proper one. In any form of closed treatment there is a danger of sepsis until the wound is healed.

DR. W. I. TERRY said that the method seemed to him irrational. He did not see the object of doubling up a mass of tunica, and fastening it up to the cord.

NEPHRECTOMY.

DR. DUDLEY TAIT also reported a case of nephrectomy in a patient aged 62. The trouble began 18 months ago with polyuria and pollakiuria. Diabetes was then diagnosed and a rigid diet enforced, causing a loss of 62 pounds. Four months later there was painful micturition and slight pyuria. Occasionally there was some tire on the right side. He was treated for cystitis by various physicians for 14 months with no benefit. Examination in the beginning of November, 1900, showed an adherent painful mass in the region of the right kidney, pus in large quantities in the urine, albumin, a few red corpuscles, numerous pelvic and a few vesical cells. The segregator (Harris) gave a decidedly purulent urine from the right side, and almost clear urine from the left. The amount from the left side was almost double that from the right side. Temperature at this time was almost invariably 37.2° C. in the morning, 39 at night; pulse, from 70 to 80. Diagnosis, pyelonephritis, possibly tuberculous, with a mild cystitis. Lumbar incision November 14 showed an extremely adherent kidney. With considerable difficulty and some hemorrhage the lower three-fourths of the kidney were freed. During this dissection two pockets of pus were opened in the lower third of the kidney. Further dissection being apparently impossible, clamps were applied and morcellation done. The wound was left open. The patient's condition immediately after the operation was very satisfactory; pulse, 98; temperature, 38. The dressing was removed on the third day; the wound had then the aspect seen when clamps are used. Healthy granulations were not noted on the surface of the entire cavity until the fifteenth day. The patient had no control of micturition; it was, however, no longer painful. The daily amount of urine passed could not, therefore, be estimated accurately. It varied between 900 and 1300 gm. It contained a small amount of pus in the beginning and became almost clear during the second week. On the seventeenth day the urine contained a few leucocytes, albumin and a few vesical, but no pelvic cells. The pulse showed a marked increase as early as the fourth day, 104, and rose gradually subsequently. The treatment was salt water subcutaneously, cardiac stimulants, diuretin and milk. On the twentieth day the condition of the wound was entirely satisfactory. The granulations were present in all directions. The pulse remained high, 118 to 120; temperature at night, 38.4. Urine was clearer and more abundant. Without apparent cause a sudden change occurred during the day, pulse 134, irregular; temperature, 38. Urine greatly diminished in quantity. Notwithstanding the use of stimulants and salt solution, the pulse increased in frequency, 180, and more intermittent. The patient died twelve hours later, the twentieth day after operation.

There were at least three points worthy of discussion in this case. 1. The mistake in diagnosis made by those who saw and treated the patient during the 18 months preceding the operation. Failure to make the usual examination of the urine and urinary system is the only possible explanation. 2. Whether in the presence of multiple purulent foci in the kidney it is safer to be contented with a nephrotomy and drainage. The French school almost unanimously advises incision and drainage in the common nodular infiltration of the kidney. In the case under discussion the kidney was very friable, extremely adherent in the upper third, and two pockets of pus had already ruptured during the dissection. Nephrotomy under these circumstances would have been very easily done, but the symptoms would probably not have cleared up with such incomplete drainage. However, the question still remains: would nephrotomy, with or without secondary nephrectomy, have given a better result? 3. The condition and function of the remaining kidney. The Doctor confessed to have neglected the proper study of the case from this all-important point of view. He failed to utilize any of the recent methods of determining the function of the kidneys. The methylene-blue test, the phloridzin test for artificial glycosuria, and cryoscopy were not resorted to.

Johns Hopkins Hospital Medical Society.

Meeting held Dec. 3, 1900.

Dr. H. Barton Jacobs, in the chair.

CIRRHOSIS VENTRICULI.

Dr. Thomas McCrae exhibited, in the absence of Dr. Osler, the specimen of this exceedingly rare affection, from a man aged 48. The previous history was unimportant, except that the patient was in the habit of drinking large quantities of cold beer. The symptoms began five years ago, with acute epigastric pain, followed by loss of weight. There was no nausea or vomiting, nor other symptoms pointing to ulcer. A slight epigastric ridge was felt, which, with the absence of free hydrochloric acid and presence of lactic acid, led to the diagnosis by Dr. W. S. Thayer of carcinoma. Later the patient was seen by prominent specialists in New York, who did not confirm this diagnosis. The case came recently under Dr, Osler's care, with the additional history of a gradually diminishing ability to ingest food and loss of 100 pounds weight during the past year. A test-meal gave 90 c.c. of fluid, with total absence of hydrochloric acid. There was no anemia. Dr. Osler made a diagnosis of cirrhosis of the stomach. Dr. Finney operated and found an hour-glass constriction at about the middle of the stomach. The opening was made on the pyloric side of the stricture, which admitted only one finger, and the stricture was then divided and the opening in the stomach closed in the usual way. The patient gradually sank and died four days later. On autopsy there was no evidence of peritonitis and the stitches held well. Death appeared due to exhaustion. Sections showed great overgrowth of fibrous tissue, and there was no sign of previous ulcer.

DERMOID CYST OF MESENTERY.

Dr. J. F. Mitchell stated that a man aged 34, a healthy, robust teacher, came into the hospital complaining of pain in back and abdomen. His trouble began ten years ago, with colicky pain recurring two or three times a year, with constipation, but no fever. Five years ago, the attacks had become more frequent, recurring five or six times a year. By last summer they recurred every six weeks. Constipation was the rule, and with relief of that came relief of the pain. Three years ago, a lump, 4x3 inches, appeared below the umbilicus in the median line. On entrance to hospital a lump was found just below the umbilicus, which disappeared altogether at times. In the knee-chest posture, it fell forward and was readily moved from side to side. On deep pressure there was pain. The urine was negative and there had been no hematuria. It was scanty and high-colored during the attacks, but there was no increase afterward. The tumor was thought to be a displaced kidney. An exploratory incision was made by Dr. Finney, and it was found to be a dermoid cyst between the folds of the mesentery, about 10 cm. in diameter, quite firm, with indefinite sense of fluctuation. On slitting up the mesentery, the tumor was easily peeled out. The abdominal cavity contained a large amount of fluid, which contained leucocytes but no other cells. Examination of the cyst contents shows fat globules and fatty-acid crystals, but no cholesterin.

Dr. T. B. Futcher said the diagnosis had been in doubt; Dr. Osler had been non-committal, spoke of mesenteric tumor and also intestinal tumor, but inclined more to a tumor of kidney. He himself had also inclined to the latter opinion. Dr. Young had made a cystoscopic examination and drawn the urine from either kidney; this was normal, which should have impressed them more than it had. The contents of the cyst resembled the stools in "fatty diarrhea."

ACUTE PANCREATITIS.

Dr. Jos. C. Bloodgood reported two cases. The affection is rare and the diagnosis not often made. Early diagnosis with operation may be followed by recovery. In 12,000 surgical admissions here, and perhaps an equal number on the medical side, there have been three cases, one of these being hemorrhagic and two of the suppurative form. There were only two cases of cysts of the pancreas and ten or twelve of carcinoma of the pancreas. The first case was one of acute hemorrhagic pancreatitis. There was no history of the case, but the patient came in with a diagnosis of acute intestinal obstruction, nausea and vomiting. Operation was done and areas of fat necrosis and small hemorrhages were found. The wound was closed and death was expected, but the patient recovered.

The second case was in a man 47 years of age, with a considerable excess of fatty tissue. The only evidence of previous illness was symptoms of indigestion for some years. Seven months before present attack he had had an attack of jaundice, lasting three weeks. Present attack began twenty-one days before operation; he was suddenly seized with nausea and vomiting and intense cramp-like pain. Five days later he still had great pain, with distension, nausea, vomiting; the temperature was 105 degrees, the first time it had been noted to be febrile. There was vomiting of pus at intervals. The seventh day his physician noticed a tender mass in the right lumbar region. Patient also noted swelling on right side. There was no marked rigidity. He had chills and fever. Tenderness developed in the mass, but there was no jaundice. On admission patient was a large man, with pulse 110-120, and a tumor more visible to the right side of abdomen, but more palpable to the left of the umbilicus and below it. The right lumbar curve was fuller than the left. There was distinct resistance in the site of the tumor. The surface of the tumor was irregular, but smooth. Its lower margin moved on inspiration; over it was doubtful tympany. The dulness of the tumor was continuous with that of the liver. There was continuous fever. Leucocytes numbered 20,000. He became slightly delirious and stupid. These symptoms continued, with dry and coated tongue, pulse of 130 and dorsal decubitus. The mass was distinctly outlined, occupying chiefly the umbilical and epigastric region and more toward the right side—a large immovable mass feeling like the omentum around an appendicitis. The dulness was less between the tumor and liver. He never had appendicitis in the middle line, although he had it to the right of the gall-bladder. So bad was the patient's condition that operation was done under cocain. On entering peritoneum the omentum was seen to be studded with areas of fat necrosis, making the diagnosis positive. There was an evident tendency to bleed. Pus was encountered, first yellow and gelatinous, later brown, with a distinct, sweety odor. The pus came out slowly, at least 250 c.c. draining out. Death followed within twelve hours with symptoms of infection. Gall-stones were found. The third case presented practically the same history. There was a distended stomach and a definite area of tympany between the tumor and liver. There was a history of morning nausea and vomiting of two year's duration. Patient was a stout man, an excessive user of beer and alcohol. There was an excess of subcutaneous fat. Patient had been sick four or five days before admission. There was a well-defined tumor, not moving on respiration. At the operation done by Dr. Finney the tumor was situated beneath the omentum. There was no improvement in the patient's condition. The wound was reopened and a large pancreatic abscess found; as soon as this was opened and drained nausea and fever ceased. The patient is living and well to-day, and is seen now and then. Six months ago he had only a suggestion of gall-stones. This patient has no recollection of coming to the hospital. Such patients look iller than those with appendicitis or cholecystitis. He has noticed in connection with gall-stones an induration of the head of the pancreas. It is well known, especially from the researches of Opie, that we get interstitial pancreatitis from obstruction of the pancreatic duct in this way.

Philadelphia County Medical Society.

Meeting, Dec. 12, 1900.

President Dr. J. H. Musser, in the chair.

RESECTION OF ULNAR NERVE.

DR. ERNEST LAPLACE presented a case of nerve severed for nearly one year and in which there had been paralysis and contracture of the fingers. The injury had resulted from a fall on a sharp object. He had made a dissection and found the two ends of the nerve separated a distance of about 1½ inches. The lower end was enveloped in cicatricial tissue. Both ends had been freed from the surrounding tissues and gradual traction made until the two ends were brought together, after which the nerve was united end to end by ten very small silk sutures inserted by means of the smallest needle possible. Before the operation there had been complete paralysis, but on the following day the patient could move the fingers, and on the fourth day he could move the hand; sensation is almost normal, thus showing that many of the severed fibers have found there fellows. From this fact the result might demonstrate the value of en-to-end union in severed nerves rather than splicing or overlapping.

DR. T. S. K. MORTON spoke of a similar case he had operated upon several years ago in which sensation had returned in the parts within two or three hours after the operation for union of a severed nerve.

LYMPHATIC AND PORTAL INFECTION FOLLOWING APPENDICITIS.

DR. JOHN C. MUNRO, of Boston, began by stating that infection of the retroperitoneal lymphatics is more common than is generally supposed. A continued temperature after operation for appendicitis should indicate infection of the retroperitoneal lymphatics. When there is a chill, high fever and jaundice, infection of the portal system should be suspected. When the former is found in any given case it should be looked on as of appendicular origin. The speaker then detailed a series of cases to illustrate the symptoms set up by infection of this character. The onset is not always sudden, but may occur several weeks after the operation and leading to the formation of abscess. In one case there had been a slight elevation of temperature for three months following an operation for appendicitis and later a retroperitoneal abscess was found. In another case subsequent to operation the patient developed chills and fever accompanied by jaundice, but aspiration—which is not a good procedure—failed to find pus in the hepatic region. In one case an abscess of liver was found which had resulted from appendicitis.

From the history of many cases he had made the following deductions: 1. In appendicitis there is nearly always infection of the retroperitoneal lymphatics. 2. This infection may date its origin previous to the onset of appendicitis. 3. Infection of the lymphatics is more common than pylephlebitis. 4. The infection shows a tendency to spread by way of the lymphatics. 5. These complications demonstrate the value of free openings and drainage following operations for appendicitis.

DR. H. A. HARE spoke of the venous and lymphatic vessels and their relationship in the region of the appendix. A study of these shows the readiness by which infection may reach the liver and contiguous regions. The relation existing between the blood-supply of the appendix and liver is a close one. The essayist had touched on the fact that symptoms often indicated the affection of distant organs such as the spleen, stomach or other viscera when the main fault might be located in the appendix. This fact might be due to the widespread infection resulting from this condition.

DR. JOHN B. ROBERTS believed that physicians as well as surgeons were too prone to look on appendicitis as only a local condition, but the symptoms presented should call for a more careful study of the question. He disapproved of introducing aspirating needles as a diagnostic sign of hepatic abscess.

DR. EDWARD MARTIN was afraid that perhaps too many cases of doubtful nature would now be attributed to this condition. In his opinion infection of the retroperitoneal lymphatics was somewhat rare. A free incision with drainage in appendicitis would usually prevent involvement of the lymphatics. As to the use of a trocar in making explorations for abscess, it might in some cases be better than an incision which might lead to fatal hemorrhage, as instanced by a case which he had seen.

DR. JOHN G. CLARK stated that within the past three or four months he had been making a series of experiments to determine the very point made plain by Dr. Munro. He had found that after carmin granules had been injected into the more dependent parts of the peritoneal cavity of rabbits and the animal subsequently kept in an upright position after the lapse of five hours carmin granules could be found in some of the lymphatics in the sternal region. This showed that they could easily make their way through the diaphragm. After the lapse of a longer period of time carmin granules could be found near the liver, kidneys or gastric regions. He had been able also to find these granules in the bone marrow. These results only seem to follow the injection of the granules into the more dependent portions of the peritoneal cavity or adjacent to the pelvis which might therefore go to confirm the clinical observations of Dr. Munro in regard to infection of the retroperitoneal lymphatics and venous circulation in cases of appendicitis.

DR. SIMON FLEXNER thought the condition might be allied to that seen in typhoid fever and other infectious diseases when thrombosis occurs. It requires only a very short time for bacteria to be distributed throughout the body. This had been demonstrated by an observer who, after injecting the bacillus prodigiosus, had, after five minutes, found it in the bile.

Chicago Pathological Society.

Meeting held Dec. 10, 1900.

URETERO-INTESTINAL ANASTOMOSIS.

Dr. F. R. Zeit discussed an experimental study of the pathology and bacteriology of ureteral implantation into the rectum as practiced on 120 dogs, and implantation of the trigonum into the rectum on 21 dogs.

The operations on the animals were done by Drs. Franklin H. Martin and Reuben Peterson with a view of devising an operation for cases of malignant disease of the bladder. The paper gave: 1. A complete résumé of the literature of bilateral uretero-intestinal anastomosis on man and animals, showing that no better results can be expected in man than those obtained in animal experiments. 2. The results of careful pathological and bacteriological examination of the operated animals. 3. The results of animal experiments with a view of producing immunity to the bacillus coli communis.

The conclusions reached are, that no matter what the operation employed with a view of preventing ascending renal infection, the pathology of ureteral implantation into the rectum is the pathology of pyelonephritis and its sequelæ. All the variations of this form of suppurative nephritis were observed in the operated dogs, from the earliest beginning of ascending infection a few days after the operation up to the healed process with induration and cicatrization and resulting granular contracted kidneys, which were found in all dogs that have recovered from the primary results of their pyelonephritis. Numerous microscopic specimens and photomicrographs were shown to prove that infection could have taken place only by way of the ureters, pelvis of kidney and uriniferous tubules, and that the pyelonephritis was caused by the bacillus coli communis.

Most of the dogs died of peritonitis due to leakage of urine and general sepsis and pyelonephritis during the first ten days, the primary mortality being 84 per cent. Dogs living a longer time died of pyelonephritis, pyelonephrosis and pyemia, or recovered from the pyelonephritis with contracted kidney. Specimens were shown of other dogs which appeared to be in perfect health 210, 300 and 405 days after operation. All had granular contracted kidneys, and still showed evidences of former pyelonephritis. The ureters are not much diseased, although usually dilated, no matter how severe a pyelitis or pyelonephritis was present. The bladder is always found to be infected by way of the urethra. In all cases where the bladder had not been removed, it was found to contain a purulent fluid teeming with bacteria, mostly staphylococcus albus and bacillus coli communis. A purulent cystitis was found also when the operator squeezed out the bladder thoroughly before closing up the abdominal wound after the operation.

Operative results on 21 dogs with implantation of trigonum into rectum were more favorable. Specimens from several dogs were shown, one of which was killed on the thirteenth day after operation. One ureter with trigonum implanted showed a normal kidney. The other ureter implanted without vesical mucosa resulted in a violent pyelonephritis.

Buffalo Academy of Medicine—Medical Section.

Meeting held Dec. 11, 1900.

PERIODIC VOMITING.

Dr. Charles G. Stockton reported a case of what was held to be characteristic cyclic or periodic vomiting in a child. It first appeared when the child was 3 years old, and occurred at intervals of six or twelve weeks, thereafter, for a period of five years, when the attacks declined in frequency and severity, and have now quite disappeared. The seizures were ushered in by a day or two of dulness with inactivity of the bowels: the appetite was usually good. The vomiting occurred suddenly and was repeated sometimes with severe retching at intervals of one-half or one hour. The ejecta appeared to be pure gastric juice, rich in hydrochloric acid, which acidity declined as the attacks passed off. After vomiting for about a week, during which there was very alarming prostration, constipation of the bowels and diminution of the urinary output, improvement appeared as suddenly as the onset. In forty-eight hours the child seemed as well as ever, and continued to be perfectly well in the interval. The affection was apparently in no way related to any other ascertainable condition, and was not precipitated by overeating or other faults in hygiene. The writed assigned this case to a group which he thinks differs from the cases reported by Leyden, which occurred in adults, and those reported by Boas, in which there was hypochlorhydria, and from other groups not answering to the description of pure cyclic vomiting in children. Hypodermoclysis and enteroclysis were recommended as means of averting the dangers of collapse. Several fatal cases were referred to.

TREATMENT OF DISEASES LOCALLY BY HOT-AIR.

Dr. Prescott Le Breton referred to the introduction of superheated dry air in England in 1893 as a remedy to alleviate pain and cure disease. A description of the apparatus which essentially consists of 1, an oven to enclose the affected parts; 2, a suitable covering for the skin to absorb perspiration and prevent blistering, and 3, some means of generating heat.

The treatments to any given part occupy from one-half to one hour, and the temperature reached in the bath varies from 250 to 340 F., the heat varying according to the sensation of the patient. Massage is indicated afterward, especially if there is any swelling or exudation. The effects of this extreme heat locally are a relaxation of the tissues, an increase in the circulation with dilation of the blood-vessels, a numbing of the sensory nerves, a marked perspiration and often a change from an unhealthy to a healthy metabolism. Swelling is diminished, pain is relieved, stiffened joints and muscles move more freely. The writer details the effect of this treatment in 12 selected cases, including Colles fracture, sciatica, muscular rheumatism, contusion to lumbar region, coccygodynia, rheumatoid arthritis, neurasthenia spinalis, old dislocation of hip, subacute rheumatism, and neuritis, in all of which much good was noted with oftentimes a cessation of all symptoms. A like result was also noted in 35 cases selected from other observers.

Therapeutics.

Vapor-Bath.

The following simple method for giving a vapor-bath to patients who have to be treated in the recumbent position is recommended by *La Presse Médicale*: Spread a blanket over the bed, upon which place the patient, dressed only in his gown: under each foot and at each side of the body place a well-corked stoneware jar of boiling water. Before being placed in position, each jar should be covered with a damp towel and afterward covered with a piece of flannel. After the jars are placed in position the blanket is folded over the patient and he is then covered with another blanket and an eiderdown quilt. In a few minutes a profuse perspiration is brought on, lasting for a time, varying according to circumstances. If it is advisable to increase the perspiration, warm drinks may be given. When the patient is taken out of his vapor-bath, the blankets on which he lies and the jars are withdrawn without uncovering him, and his body should be dried under the second blanket and the quilt, which are allowed to remain. After twenty or thirty minutes his linen may be changed.

Nephritis Following Scarlet Fever.

J. Lewis Smith recommends the following mixture in order to increase the elimination by the bowels, skin and kidneys:

℞.	Potassii acetatis		
	Potassii bicarb.		
	Potassii citratis, āā	ʒii	8
	Infusi tritici repentis, q. s. ad	℥viii	256

M. Sig. A teaspoonful every three or four hours in water, for a child of 5 years.

Treatment of Impetigo Contagiosa.

Engman, in *St. Louis Med. Review*, outlines the following treatment in impetigo: The bullæ should be opened and the contents caught in absorbent cotton and not permitted to run over the skin. Free the surface of the diseased epidermis by clipping it off close to the bullæ, and dust with an antiseptic powder. When the disease is widespread and there is much crust-formation, a bland oil, such as carron-oil, liquid albolene, or olive-oil, to which has been added 2 per cent. of salicylic acid, should be used. This should be well rubbed over the surface, the crust detached, and the following dusting-powder applied:

R.	Acidi salicylici	gr. xx	1|33
	Acidi borici		
	Zinci oxidi		
	Amyli, āā	ʒii	8

M. Sig. Apply locally.

Baths are contraindicated. Ointments seem to irritate, consequently the application of the bland oil to soften the crusts followed by the antiseptic dusting-powder is regarded by him as the most successful method of treatment.—*Med. Standard.*

H. H. Whitehouse, in "Twentieth Century Practice," recommends the removal of the crusts by washing with white castile soap in warm water, followed by the application of a mercurial preparation:

R.	Hydrargyr. ammoniati	gr. x	|66
	Adipis benzoinati	℥i	32

M. Sig. Apply locally twice daily; or

R.	Ichthyoli	gr. xv	1
	Ung. zinci oxidi q. s. ad	℥i	32

M. Sig. Rub in well *two or three times daily.*

The latter acts very well, especially when the crusts are adherent, in which case it should be spread thickly on lint and bound on. He states that in all cases, but particularly in the bullous form, ichthyol in 3 per cent. strength is very effective.

Removal of Warts and Moles.

W. C. Abbott applies the ethylate of sodium for this purpose in the following manner: The growth should be walled in with a piece of wax, vaselin or mutton tallow and then a drop of the above solution should be placed on the tip of the growth. After two or three minutes any remaining portion should be absorbed with a blotter. A caustic effect occurs which kills quite deeply; a scab is formed, which peels off, leaving the part normal.

[Sodium ethylate is formed by the combination of metallic sodium and pure alcohol. It forms a white powder, which is soluble in water or alcohol. It is generally used in an aqueous solution of 10 per cent. strength.]

Sweating of Feet—Hyperidrosis Pedis.

The *Pharmaceutical Post* publishes the following formulæ for treatment of excessive sweating of the feet:

R.	Balsami *peruviani*	m. xv	1
	Acidi formici	ʒi	4
	Chloralis hydratis	ʒi	4
	Alcoholis—absolute—q. s. ad	℥iii	96

M. Sig. Apply by means of a local pad of wool; or

R.	Acidi borici	gr. xv	1
	Sodii boratis		
	Acidi salicylici, āā	ʒvi	24
	Glycerini	℥iss	48
	Alcoholis, q. s. ad	℥iii	96

M. Ft. lotio. For local application.

Sajous' Annual contains reports of good results obtained by Legoux in treatment of cases of obstinate perspiration of the feet with offensive odor, of several years' duration. He first bathed the feet for several days in a weak infusion of walnut leaves and applied the following mixture twice daily:

R.	Liq. ferri chloridi	℥i	64
	Glycerini	ʒv	20
	Essentiæ bergamottæ	m. xl	2|66

M. Sig. Apply to the feet twice daily.

For Disinfecting the Mouth in Infectious Diseases.

R.	Acidi carbol	ʒi	4
	Glycerini	ʒvi	24
	Aquæ destil., q. s. ad	℥ii	64

M. Sig. Apply to the buccal mucous membrane with a pledget of cotton on an applicator; or

R.	Acidi carbol.	ʒi	4
	Spiritus camphoræ	ʒii	8
	Olei olivæ, q. s. ad	℥ii	64

M. Sig. To be applied locally by means of an applicator; or

R.	Acidi carbol	ʒi	4
	Alcoholis—pure	ʒii	8
	Glycerini	ʒvi	24
	Aquæ destil., q. s. ad	℥ii	64

M. Sig. For local application by means of a swab.

Care should be used that none of the solution drops into the larynx. This can be avoided by pressing the swab against the side of the bottle before applying it.

Thiocol in Tuberculous Cases.

Braun, in *Klin. Ther. Woch.*, has found that thiocol is better tolerated by the stomach than the other drugs of the creosote class. It has given considerable relief in tuberculous cases; to those suffering from chronic bronchitis especially.
—*Internat. Med. Mag.*

[Thiocol is the potassium salt of guaiacol-sulfonic acid. It contains about 60 per cent. of guaiacol. It is a fine white powder, which has a taste at first bitter then sweetish. It surpasses the other preparations in that it is free from odor, is very soluble in water, rapidly absorbed by the mucous membranes and is free from irritating action. The dose is eight grains, gradually increased to thirty or forty grains, three times a day.]

The following is the most preferable way of prescribing it:

R.	Thiocol	ʒiii to ʒiv	12-16
	Syr. aurantii, q. s. ad	℥iii	96

M. Sig. One *teaspoonful three times a day.*

Removal of Foreign Bodies in the Nose.

Children, while playing with small bodies, such as marbles, buttons, peas, beans, and grains of different kinds, very frequently place them in the nose, and they are removed with difficulty, as well as causing great fright to the child. Keating, in his treatise on "Diseases of Children," recommends that the *child, if old enough*, be instructed to blow hard or to cause sneezing by tickling the membrane of the nose or by the application of snuff. The body can frequently be dislodged by having the child take a full breath and then give him a smart blow on the back. If not dislodged then close the nostril which contains the body and blow into the other nostril through a rubber tube, instructing the patient to keep the mouth closed; suddenly release the closure of the side occupied by the body. If this does not accomplish the purpose then it will have to be drawn out by forceps or other surgical means resorted to.

Treatment of Gonorrhea.

The *following* prescriptions, recommended in treatment of gonorrhea are published in the *N. Y. Med. Journal.*

R.	Extracti zeæ fluidi—corn silk		
	Spts. etheris nitrosi, āā	ʒss	16
	Balsami copaibæ	℥i	32
	Mucilaginis	℥ss	16
	Aquæ destil, q. s. ad	℥vi	192

M. Sig. A dessertspoonful to be taken three times a day in water.

[The therapeutic agent in this prescription is the volatile contained in copaiba and it should be used more extensively in the subacute stage of gonorrhea. Zea and copaiba both contain resins which promote diuresis.]

FOR WATERY GLEET.

R.	Acidi tannici	gr. iv	|25
	Mucilaginis	ʒi	4
	Aquæ, q. s. ad	℥i	32

M. Sig. Use as an injection two or three times daily.

Psoriasis.

The *British Med. Journal* reports the treatment of psoriasis applied by Balzer and Mousseaux, by means of oil of cade baths. The following formulæ are prepared:

℞.	Saponis—soft	℥iii	96	
	Aquæ	℥vi	192	

To this emulsion oil of cade is added in the proportion of:

℞.	Olei cadini	℥iii	96	
	Emul. saponis	℥viii	256	

M. Sig. Add the entire amount to one bath—thirty gallons of water.

The patient is instructed to use plain soap and water to remove the scales before taking the bath. Although not stated, it is supposed that the temperature of the bath should be suited to the patient, as well as the length of time the patient is to remain in it.

Crocker recommends the following to reduce the hyperemia after the scales have been removed:

℞.	Calaminæ	℈ii	2	66
	Zinci oxidi	ʒss	2	
	Liq. calcis			
	Olei olivæ, āā	℥ss	16	

M. Sig. Apply locally after removing the scales by means of soap and water or by immersion in a warm alkaline solution.

Herpes Genitalis.

W. F. Robinson states that caustics should never be used. as grave ulceration may follow their use. He employs the simplest antiseptic washes and observes cleanliness by immersing the parts in a warm boric-acid solution or bathing with the same twice daily and dusting afterward with the following:

R.	Europhen			
	Acidi borici. āā	℥i	32	

M.

Duhring recommends the following:

R.	Zinci sulphatis			
	Potassii sulphidi. āā	ʒss	2	
	Spts. vini rectificati	ʒi	4	
	Aquæ	ʒvii	28	

M. Sig. Shake and apply frequently.

Eczema of Female Genitals.

The following is recommended by Von Sehlen:

R.	Ichthyoli	ʒiss	6	
	Pulveris amyli	℥i	32	
	Vaselini	℥ii	64	

M. Sig. Apply locally twice a day.

—*Encyc. Pract. Med.*

Tuberculosis.

Daly, in *The Medical Record*, recommends the following pill in tuberculosis:

℞.	Camphoræ	gr. ii		13
	Heroin	gr. 1/12		005
	Creosoti	mi		06

M. Ft. pil. No. i. Sig. One such pill three times a day and at midnight.

He reports six cases and says he has found this formula superior to any he has used in treatment of the cough. It is also of great benefit in the cases of nervous depression found in tuberculous subjects. The disorders of the stomach, which are sometimes difficult to combat in phthisical patients, may be indirectly due to cough and this remedy therefore gives relief. When the cause is a local one he has had the best results with the following formula:

℞.	Bismuthi subnitratis	gr. xv	1	
	Guaiacoli carbonatis	gr. i		06
	Heroin	gr. 1/32		002

M. Ft. tablet No. i. Sig. One tablet after each meal.

The guaiacol has been used in this formula in small doses because it has a tonic effect in the stomach. and the heroin because it has some analgesic power. In the use of this last tablet care must be taken to prevent the constipation which the bismuth may produce.

Ovarian Neuralgia.

℞.	Camphoræ monobromatæ	gr. iss		1
	Pulveris capsici	gr. ii		13
	Confectionis rosæ, q. s.			

Sig. One such pill every three or four hours.

—*N. Y. Med. Jour.*

Administration of Quinin to Children.

H. B. Sheffield, in Med. Times and Register, recommends euquinin, which is a perfected and practically tasteless preparation, to be given children, as it is a palatable preparation. It may be prescribed in simple syrup. It has the further advantage over quinin in being less apt to produce nausea and tinnitus. For grown-up children he prescribes the following:

℞.	Quininæ sulphatis	gr. xxx	2	
	Acidi sulphurici dil.			
	Ess. menthæ piperitæ, āā	ʒss	2	
	Syr. yerbæ santæ comp., q. s. ad	℥iii	96	

M. Sig. Two teaspoonfuls every three hours.

He gives iron in the following combinations:

R.	Vini ferri amari			
	Elixiris aurantii, āā	℥i	32	

M. Sig. One teaspoonful three or four times a day; or

R.	Ferri et ammon. citratis	gr. xv	1	
	Spts. vini gallici	℥ss	16	
	Essence pepsini	℥i	32	
	Syr. simplicis, q. s. ad	℥ii	64	

M. Sig. One teaspoonful three or four times a day; or

℞.	Tinct. ferri chloridi	ʒi	4	
	Glycerini	℥ss	16	
	Syr. zingiberis	℥i	32	
	Aquæ, q. s. ad	℥ii	64	

M. Sig. One teaspoonful three times a day after meals.

Medicolegal.

Knows the Sex That Commits Rape.—Section 4221 of the Revised Statutes of Utah of 1898 makes it a felony for any person to carnally and unlawfully know any female over the age of 13 years and under the age of 18 years. The word "male" does not appear in the statute, yet it is well known, the Supreme Court of Utah says, in the case of State vs. Williamson, that no one but a male person could be indicted for the specific offense of rape; and the court, it continues, would construe the statute to mean that a male person only could consummate the offense named therein. So it holds that the information in such a case need not specify the sex of the defendant. Or, more generally speaking, it holds that in a criminal prosecution, where the offense charged is such as only a male person could consummate, the information need not specify the sex of the defendant.

Physician Carelessly Accelerating Death.—When the case of Gray vs. Little was before the Supreme Court of North Carolina for the first time it held erroneous, as stated on page 162 of The Journal A. M. A., of July 21, 1900, an instruction to the effect that only nominal damages could be recovered for a death where it was only accelerated by the malpractice and negligence of the defendant. But it was sheer inadvertence on its part, it says, on the reappearance of the case before it, that it then referred to an instruction that was asked and not given in a way which led the lower court on the second trial to submit an issue as to punitive damages. The state statute which authorizes the recovery of such damages as are a fair and just compensation for the pecuniary loss resulting from a wrongful killing, which confers the right to recover in such cases, it holds, restricts the recovery to compensatory damages. But is says that it is difficult for it to comprehend how the jury could have returned a verdict of $100 as compensation for the death by malpractice, as was found, of a wife and mother 33 years of age, and it suggests that considerations of humanity would seem to require that the case should be investigated by the solicitor for the district, if the criminal arm of the law has not already been invoked.

Falsely Charging That One Has Leprosy.—To falsely say of one that he has leprosy is slander, and to publish it by writing is a libel, Mr. Justice Gaynor holds, in Simpson vs. Press Publishing Company, at a special term of the Supreme Court of New York, Kings County. Nor does he consider that it makes any difference in this regard if the progress of science has revealed, as was contended in this case, that leprosy was erroneously classed as infectious or contagious. It remains a term of slander, he holds, until the law is changed. Every disease that is infectious or contagious is not embraced within the definition of slander. The bane in the charge of leprosy which made the courts classify it as slanderous was its tendency to cause one to be shunned and excluded from society, and that still exists. But the definition of libel is much broader than that of slander, and any false publication by writing which exposes one to ridicule, hatred, contempt or obloquy, or causes him to be shunned or avoided, is a libel in and of itself, though if spoken it might be no slander. Hence, to falsely charge one in writing with having any repulsive disease or condition which would necessarily cause him to be shunned or avoided, the judge says, would be libel, but it would not be a slander if spoken unless it was one of the diseases embraced within the definition of slander. Moreover, the point that the complaint was insufficient for not stating that leprosy is contagious or infectious, he holds was not well taken, as such an allegation is neither usual nor necessary, any more than to formally plead that to steal is a crime, for the court takes notice of what words constitute slander per se.

Venue of Actions Against Trustees.—The Civil Code of Kansas, after specifying the venue of various classes of actions, local and transitory, provides that every other action must be brought in the county in which the defendant, or some one of the defendants, reside or may be summoned. Under such a provision the Supreme Court of Kansas holds, in State vs. Hornaday and others, a summons to a member of the board of trustees of the charitable institutions of the state may rightfully issue from the court of any county in which such member may be, whether resident there or not, and may be served upon him there; and, when so issued and served, process may rightfully issue from such court to other members of the board, and be served upon them in other counties. It says that the members of the board are possessed of an official character, which accompanies them throughout their respective terms. While, as individual members, apart from their fellows, they may not be able to transact public business, yet they do not take on and put off their official character as the exigencies of the public service require them to convene or separate. They are each of them public officers, liable at any time to be called to the discharge of some of their public duties, and liable at any time to receive notice of public interests requiring their convocation and attention. The duties performed by them do not require their assembly at any set time or at any particular place, but they may meet when and where, within the state, the public service may be best conserved; and they are therefore, the court holds, clothed, everywhere in the state and throughout their respective terms, with the responsibilities and official character of their positions.

Opinions as to Age.—The fourth appellate division of the Supreme Court of New York says, in the case of Hartshorn vs. the Metropolitan Life Insurance Company, that it is well settled that expert evidence is proper where the age of a child is at issue, and that it has often been received concerning the age of an absent adult. But, to entitle such evidence to any weight, the facts and circumstances upon which the opinion is based, the court holds, should be given, and the witness should first describe, as far as practicable, the appearance of the individual whose age is in question. It also remarks that it is common knowledge that an opinion is ordinarily of but little value as to the real age of a person between the ages of 30 and 60. Here, one of the principal defenses to an action to recover life insurance was an alleged breach of warranty on the part of the insured in representing herself to be many years younger than she really was. According to the undisputed testimony of a granddaughter of hers, the insured, if she gave her age correctly in her applications for this insurance, was a grandmother at the age of 27 years, which, although not impossible, the court holds would be sufficiently unusual and extraordinary to require further proof than a mere opinion as to her age, before the conclusion that such fact was established by the evidence would be warranted, and the presumption raised by the baptismal record would be fairly overcome. The opinion referred to was that of the physician who examined the woman on each of her two applications for insurance. He testified that he had known her for three or four years, had made calls in the family professionally, but not upon her, and had called at the house frequently to see others, perhaps two or three times a month, for some time; that she had black hair, was a strong, active woman, appeared in good health, and her occupation was that of a housekeeper. Upon this foundation, he was permitted to testify that he formed an opinion, in a general way, that she was at the time in question about 51 or 52 years of age. But the court says that it is not satisfied that a sufficient foundation was laid to render this evidence admissible, and, again, it declares that upon the facts disclosed by him the testimony of the physician was entitled to but little weight upon the question of the exact age of the insured.

Indictment and Dying Declarations in Abortion Case.—In State vs. Meyer, where the indictment charged an attempt, without lawful justification, to cause the miscarriage of a woman pregnant with child, the Supreme Court of New Jersey held that it was error to admit in evidence the dying declarations of the woman. The reason it assigned for this was that as the legislature, in the crimes act of 1898, declared the act of the accused to be high misdemeanor, whether the woman or child died in consequence thereof or not, the death of either was not an essential element of the crime, but was really a fact to be considered in fixing the penalty. But this reason the Court of Errors and Appeals of New Jersey does not think sound. It says that while it is true that the statute calls the prohibited conduct a high misdemeanor, whether the woman or child die in consequence thereof or not, yet, on due attention to all its provisions, it clearly appears to describe two high misdemeanors—one where the woman or child dies in consequence of the operation, and the other where death does not ensue. And it deems it indubitable that, to warrant the severer sentence, the indictment must charge all the statutory constituents of the more aggravated crime. Its distinguishing feature, the death of the woman or child as a consequence of the attempted abortion, must therefore be alleged in the indictment, and thus made the subject of investigation and proof at the trial. Then, when the death of the woman is thus charged as an element of the offense, necessary to be proved in order to establish against the accused the graver crime and subject him to the severer punishment, her dying declarations, the court holds, are legal evidence. It says that it is aware that the question whether dying declarations can be received when the indictment does not specifically charge either murder or manslaughter has been answered in the negative by some tribunals whose judgments are entitled to very great respect. Nevertheless, after due consideration of those decisions, it prefers to hold that, on the trial of an indictment charging the defendant with the statutory misdemeanor of attempting to cause the miscarriage of a woman pregnant with child, in consequence whereof the woman died, the dying declarations of the woman are legal evidence. Of course, under this decision, an accused person, the court goes on to say, may be exposed to the danger of having the dying declarations of a woman put in evidence when her death is charged as the consequence of an abortion, but is not fully proved to have resulted therefrom, and thus they may be used in the jury room as evidence to convict him of abortion merely, without resulting death. However, such a danger may always exist when evidence is legally received by the court for a purpose not ultimately accomplished, and must be guarded against, as far as possible, by appropriate instructions from the court.

Right of Applicant for Registration to Hearing.—Section 13 of chapter 63, of the New Hampshire Laws of 1897, provides that "every person who is a practitioner of medicine and surgery in this state prior to the passage of this act shall be, upon satisfactory proof thereof to the regent and upon the payment of a fee of one dollar, entitled to registration," and a certificate of the facts which shall entitle him to practice medicine. An applicant furnished statements of three residents to the effect that he attended them as a physician prior to the passage of the act, and a certificate of the city clerk that he had certified to a death in 1896. His application, however, was denied because he did not comply with a rule of the regent requiring the applicant to furnish certificates of a member of one of the medical societies mentioned in the act and of two well-known citizens that he was a practitioner of medicine and surgery. Now, a practitioner of medicine and surgery, the Supreme Court of New Hampshire says, in Hart vs. Folsom, is a physician and surgeon who habitually holds himself out for the practice of the profession. But the language quoted, it thinks, raises the question of whether it is enough for the applicant to show that he had been such a practitioner in the state at some time in the past, or whether he must show that he was one when the act was passed. The language, it says, seems to refer to the present time—"every person who is a practitioner"—and, although these words are qualified by the expression "prior to the passage of this act," it holds that they can not reasonably be held to refer to persons who had been practitioners, but had ceased to be such when the act was passed. So it thinks that a fair construction of the language is that only those physicians and surgeons who were in practice in the state when the act was passed are entitled to registration, a view which it believes is strengthened by a consideration of the purpose of the act. Then, it holds that it is the duty of the regent to issue a license to each applicant who comes within the provisions of the act. Whenever application is made under section 13, the regent must determine whether the applicant is a physician and surgeon, and whether he was engaged in practice when the act was passed. In performing this duty he acts in a judicial capacity, and is bound to receive and consider all evidence that legally bears upon the questions. If, for any reason, the applicant is unable to furnish such a certificate as the regent may require, the fact does not conclusively show that the applicant does not possess the necessary qualifications. Hence, in this case, while it denies that the applicant was entitled to a writ of mandamus to compel the regent to issue to him a certificate to practice medicine, the court holds that the regent should give the applicant a hearing, and admit all competent evidence bearing upon the questions at issue. If the evidence submitted amounted to satisfactory proof that the applicant was a physician and surgeon in practice in the state at the time of the passage of the act he should be registered; if not his application should be denied.

AMERICAN.

1. **Post-Operative Intestinal Obstruction.**—In this article the form of obstruction following abdominal section and indirectly due to it is referred to, not the adynamic type due to intestinal paralysis from peritonitis nor that due to opium, but to that caused by the plastic lymph given out from the peritoneum and favored by handling and by operative lesions of the bowels. The Trendelenburg posture, Cleveland claims, has an incalculably favorable influence in preventing this possibility. He thinks that before beginning to examine the pelvic contents after opening the abdomen it is wise to place the patient in the Trendelenburg posture and carefully cover the intestines with omentum when it is sufficiently developed, and with wet pads of gauze force them as much as possible into the upper abdominal cavity. It is necessary, as far as possible, to leave no raw surfaces, and to cover or cauterize every stump or particle of raw tissue. The use of decinormal salt solution to irrigate the abdominal cavity and leaving the cavity half filled on closing the incision is also commended, as the absorption stimulates the patient, lessens shock and may lessen also the amount of plastic lymph thrown out. The principal point, however, made by the author is the use of oxygen injections, and several cases are reported in which they were employed to advantage. Cleveland says he has been so much impressed with the efficiency of the insufflation of oxygen in every case where he has used it that he intends to always employ it hereafter after abdominal section whenever any obstructive symptoms begin to manifest themselves. It is easily obtainable, and its use is not attended with danger if ordinary care is observed. It not merely has the power to straighten out the intestines and open their lumen, but serves as a stimulant to the peristalsis. Four of the cases detailed were desperate, and in the last he is convinced that life was saved by this procedure. He also suggests that the gas may be absorbed to some degree and enter the general circulation in some form, possibly not as oxygen, and serve as a stimulant and tonic.

4. **Infantile Skin Disorders.**—Sherwell calls attention to the use of strong topical applications as the possible cause of skin eruptions in children, and thinks that the mercurial salves and preparations are especially sinned with in this way. They are usually far too strong for the ordinary use in infants. About 10 per cent. of the people, he thinks, have an idiosyncrasy which causes the milder salves and even pure vaselin to be irritating. Another cause, which he thinks is often responsible for the effect, is intestinal indigestion. Overfeeding is in many cases the primary cause of this trouble; also errors in diet, the use of coffee, tea, etc., in young children. Other points mentioned are the clothing, and he recommends for evacuations in children, mercury and chalk, in preference to rhubarb and soda, and possibly a little compound ipecac powder added.

5. **Heart Reflexes.**—Abrams calls attention to the fact that some years ago he described a phenomenon which he named the heart reflex, consisting in a contraction of the heart body from cutaneous irritation of the precardiac region. It can only be studied with the Roentgen ray. He also refers to another phenomenon which he calls the lung reflex, which can be observed without the aid of these rays. If the skin of the thorax is irritated, lung dilatation ensues. In a previous paper he has suggested the theory that the real factor involved in the Schott treatment was not due to baths and exercise as such, but to the cutaneous irritation provoked. and in accordance with this theory he has employed vigorous cutaneous friction with hand rubbing after immersions of fifteen minutes in a warm bath to increase the sensitiveness of the skin, and can claim results emulating those of the conventional Schott method. He sums up his conclusions in regard to this point as follows: 1. Lung dilatation follows the exercise and bath treatment, the lung acting as an excretory channel for the overburdened heart. 2. The cause of the lung dilatation is dependent on cutaneous irritation induced by the exercise and baths. 3. A decrease in the volume of the heart also ensues and is likewise provoked by cutaneous irritation. The physiology of the phenomenon is noticed, and he remarks that he regards the heart-reflex test as pathognomonic in differentiating dilatation of the heart from pericardial effusion. We have yet to learn its value as an index to the condition of the myocardium.

7. **Spinal Curvature.**—Phelp's article covers about the same ground as the one noticed below. See ¶15.

8. **Inflected Fissure.**—Spitzka's article is a discussion of the position and occurrence of the inflected fissure, which has been somewhat misunderstood by cerebral anatomists, as he points out. Out of 200 half-brains examined by him, absence of this fissure was seen in 40, where it occurred 22 times on the left and 18 times on the right, and it was symmetrical in both halves of 6 brains. In 91 per cent. of the remainder it was situated on a plane, caudad of an unmistakable cephalic paracentral limb, while in the remaining 9 per cent. this limb has become separated from the main paracentral stem by a narrow isthmus, but in all cases it was situated caudad whether separated or confluent; or in other words, the inflected fissure indented and lay partly within the paracentral gyrus. Other particulars in regard to the gyrus are explained in detail and the reader is referred to the original.

9. **Aural Disease.**—Thomson points out the necessity of attention to ear troubles by the general practitioner, and illustrates it by mistakes in his own experience. He mentions the different conditions that may puzzle the diagnostician and the complications that may render them dangerous. In conclusion he offers some remarks in regard to vertigo, especially the aural type. It creates the greatest disturbance of any vertiginous disorder.

11.—See Therapeutic Department.

15. **Lateral Curvature of the Spine.**—Phelps and Manton point out that not every case of so-called Pott's disease is really tuberculous. Deformities similar to those caused by tuberculosis are seen following absorption from Peyer's patches in typhoid fever. Another rare affection resulting in kyphosis is caused by inoculation of the actinomycotic germ, and still another closely simulating tuberculosis is found in osteomyelitis. The germs of osteomyelitis are much quicker in their action and will accomplish in a few days what in tuberculous affections would take many months. These four conditions are commonly included under one head as Pott's disease. Rotary lateral curvature is differentiated from tuberculosis of the spine in that it is never produced by primary inflammation. It is nearly always congenital or rachitic; paralysis of certain muscles, faulty habits of sitting, intercostal adhesions following pleuritic effusions, etc., may be its cause. In tuberculosis the diagnosis should be made before deformity occurs. As a rule, there will be night cries, pain in bending forward, spinal rigidity, etc. If the spine is flexible in its continuity there is no Pott's disease. If it is rigid this condition is certain to be present. In lateral rotary curvature the body of the vertebræ become absorbed by pressure on one side or the other. The treatment must be on rational principles. The authors describe various appliances, but especially favor

the aluminum corset as being practicable, indestructible, and when extensively perforated it makes the coolest and most agreeable of supports, and can be worn during bathing.

17. **Ovarian Cysts in Colored Women.**—The opinion that has been held for a long time that in the colored race ovarian cysts are rare is combated by Williams, who shows from various authorities that there is about as much likelihood of their occurrence in the colored race as in the white. The associated notion that fibromas were more frequent in the colored race than in the white is also contradicted by him. In sixteen years he has operated 357 times in both races and found about 2 per cent. more fibrous tumors in colored women than in the white. His work was in the Freedman's Hospital entirely for colored women, and in both races in private practice. The results are of some interest. He agrees entirely with Dr. Kelly, who has also a favorable geographical position for the study of the question, that myomas are not specially more frequent in the black than the white race.

24. **Primary Branchiogenic Carcinoma.**—Shimanck reports a case, which he thinks is rare, of carcinoma connected with branchial fissure, and reviews the literature of kindred cases.

25.—See abstract in THE JOURNAL, xxxv, p. 1172.

26. **Home Modification of Milk for Infant Feeding.**—Holt gives directions and formulas of the home modification of milk and says in conclusion that three primary formulas can be made to do duty for an entire year in the vast majority of healthy infants. With the method of calculation here given on the basis of 1/20, it seems to be much easier to pass from one formula to another of the same series than by other methods. Since the additions of sugar and lime-water are constant, it is necessary only to calculate the percentage of milk as increased by the ounce in each 20-ounce mixture. The diluent water is in all cases added in sufficient quantity to make the total. Larger quantities than 20 ounces can easily be calculated if our increase is made by 5, *e. g.*, for 25 ounces ¼ more of the milk, the sugar and the lime-water; for 30 ounces ½ more, etc. In securing the primary formula his preference is either for milk fresh from the cow, or the bottled milk, rather than for the mixtures of milk and cream, mainly for the purpose of securing greater freshness. Where milk is obtained fresh from the cow, if it is placed in a bottle and rapidly cooled in the manner indicated, not only will the cream rise quickly so that the food may be made up when the milk is only four hours old, but at the same time this rapid cooling is of the utmost advantage in checking the early fermentative changes in milk. In taking the milk from the top of the bottle it is to be remembered that the entire number of ounces specified for the primary formula should be taken, although it may not be needed to make up the milk for weaker formulas.

29.—See abstract in THE JOURNAL, xxxv, p. 579.

30. **Experiments and Experiences With the Rifle.**—Beyer's article is largely an analysis of Kocher's paper, "Zur Lehre von den Schuss-wunden," Cassel, 1895, and a comparison of the experimental results obtained by him, which coincide with the actual experiences reported in war by Senn, Nancrede, La Garde, Sir William MacCormac, Treves, Dent, and others. His conclusions coincide with those of La Garde, who says that we should conclude that the work of the experimenters agrees with the conditions found in war. The trained military surgeon can, he claims, be trusted to read the range in the character of the wound before him with at least the same accuracy as a range-finder can.

31. **Anemic Degenerative Diseases of the Spine.**—Edes reports several cases of spinal degeneration associated with anemia and discusses the condition. In one case there was a post-mortem and the results found were described. They consisted in isolated areas of degeneration in the lower lumbar region only in the posterior columns, but at the level of the first lumbar nerves there were distinct patches in the posterolateral columns and in the anterior horns. In the upper cervical region corresponding areas were also found, and in the medulla at the level of the olivaries, though ill-defined. The cause of the condition is attributed largely to toxemia rather than to anemia. It is possible that syphilis has something to do with the etiology, as English observers seemed to find this in a considerable proportion of cases. The symptoms are numbness, inability to use the hands for fine work, numbness of the feet, general weakness of motion and co-ordination, and deep reflex exaggeration. Later there may be more or less extensive anesthesia, absolute paralysis and absence of deep reflexes.

34. **Heart Disease and Pregnancy.**—The dangers of cardiac disorders in pregnancy are always obvious, but there are two possibilities: 1. Pregnancy is apt to relight an old endocardial inflammation, and the more recent the original attack the greater the danger. 2. Dangers from pregnancy affect women suffering from cardiac disease in proportion in which one pregnancy follows another. In a case of compensated valvular disease we rarely see failure in this respect in the first four months, but where compensation did not previously exist it is not likely to occur early in the pregnancy. The rational treatment in such cases is abortion, for a viable child is hardly to be expected and it would be folly to add to the overburdened heart the strain of useless pregnancy. In the second class the author includes the cases where lost compensation occurs in the last half of pregnancy and from great increase of the work of the heart the strain increases from day to day. Sometimes the failure is due to relighting of an old endocardial inflammation. When left to nature the chances are that the woman will not go to term. The question arises whether we should try to carry the mother past the seventh month, and if by the use of cardiac tonics the circulation can be restored we may be justified in waiting. Gillespie does not feel certain of the advisability of this course, but is not certain of the contrary. As a heart tonic, theoretically, the therapeutic action of strophanthus is preferable to digitalis, and is safer. Strychnia also produces good effects. The bowels should be looked after and absolute quiet insured, as exercise does not help the matter. If the condition of the heart does not improve and hyperemia of the liver manifests itself, and digestion is disturbed, and especially if the urine shows albumin with casts, medical treatment is useless. Whenever labor occurs, whether early or late, it must be conducted so as to incur as little strain as possible, and he does not think that anesthetics are contraindicated by cardiac disease. The usual methods will not suffice in induced labor. Rapid manual dilatation and extraction by the feet is the safest, as being the least exhaustive, and also offers the best possibilities of delivering a living child. The hydrostatic bags are applicable in many cases. A case is reported illustrating the points made in the paper. The author concludes that it is not safe to wait for development of the heart symptoms. They should be anticipated and in every case where the heart is in ill health forceps delivery is advisable as soon as compatible with other conditions.

36. **Spinal Cocainization.**—Fowler reports his experience in 81 cases up to the present time, in 26 involving the peritoneum. In 5 of these the analgesia was incomplete and in all the cases there was some embarrassment to the operator at one or another stage of the operation, such as vigorous peristalsis of short sections of the intestinal canal, and a certain amount of pain in 5 cases. The patients did not complain of a moderate Trendelenburg posture, but did express discomfort when an extreme pelvic elevation was employed for a long time. In 34 cases the operation was in the pelvic region, not involving the peritoneum. In two cases of varicocele the patients complained of pain when the cord was handled, but not enough to require additional anesthesia. In one case of colporrhaphy and perineorrhaphy the sensation returned too soon, and it became necessary to administer general anesthesia. In five amputation cases anesthesia was complete and the length of time it lasted was ample. In 15 cases in the lower extremities, not included in the above, a second injection was required to be made, and in one case of ligation of the internal saphenous vein the patient heard the operator call for a knife and afterward complained of pain on the slightest touch. In 3 un-

classified operations, including costal resection, nephrectomy and operation for suppurating dermoid, in the first operation the patient complained of pain when the periosteum and intracostal nerve were peeled off the bone. In the case of nephrectomy the patient disbelieved that the kidney had been removed, and in the case of suppurative dermoid the line of demarcation of anesthesia was slightly below the point where it was necessary to incise and curette. It persisted at the same height through the whole depth of the wound. The technique of the operation is described, its difficulties and certain disagreeable features that occur, such as vertigo, vomiting, involuntary defecation and urination, which occurred in about one-eighth of the cases, and were unpleasant both to the patient and to the operator. His cases were not selected ones. He has no personal knowledge of any deaths from spinal cocainization, and his experiments with other drugs than cocain are not altogether satisfactory, though he has found the combination of antipyrin and cocain to give somewhat better results so far as the analgesia was concerned. In spite of favorable results, he wishes to say that he does not consider this the ideal method of anesthesia, but that it will have an important place and sphere of usefulness. Further trial and the study of a large number of cases will be required to establish its limitations and dangers.

39. **Hysteria.**—Fraenkel has had three cases of fatal hysteria and discusses the possibilities. He asks three questions: Is hysteria curable? He answers in the affirmative. On what conditions does this curability depend? While we are still awaiting the pathologist's solution of hysteria, the answer to this question is somewhat difficult, but he is inclined to think that monosymptomatic cases are most indicative of serious lesions. The symptoms are generally discussed, and he divides the disease into three types: 1. Predominantly mental forms, hysteric psychoses with more or less pronounced somatic symptoms. 2. Predominantly cerebrospinal forms. 3. Predominantly splanchnic forms, where the symptoms are mainly of irritation or paralysis of the motor or sensory side of the splanchnic nervous system. In all these three groups we have the symptom-complex of hysterical seizures. The prognosis of the first two groups is, according to his experience, more favorable than the prognosis of that of the third, which has sometimes been disastrous. To answer the third question, "Is hysteria ever fatal?" he notices the authorities that previously reported fatal cases, and details his own. He accredits the deaths to: 1, spasm of the respiratory mechanism; 2, inanition from prolonged hysterical anorexia or vomiting; 3, paralysis of the circulatory or alimentary apparatus, in his last case with a pseudo-peritonitis or a pseudo-ileus. However, it may be with genuine uncomplicated hysteria, death, when it occurs, is due to irritation of the splanchnic and vegetative functions, and cases of this type are to be judged cautiously as regards their future prospects.

42. **Abortive Treatment of Infantile Pneumonia.**—Illoway answers the question whether pneumonia can be aborted, in the affirmative, according to his own experience, and maintains that we have long had the means wherewith to do it. He divides his cases into two groups, according to the therapeutic treatment adopted. In the first class he found benefit from the combination of tinctures of veratrum viride and of aconite, usually giving 6 drops of the veratrum and 2 of the aconite in a one-ounce mixture for children of several years of age and in proportion for infants—a teaspoonful at short intervals until four or five doses are taken and then at longer intervals. In each case the disease was quickly brought under control. In the second class of cases his treatment was infusion of digitalis, though the first combination of aconite and Norwood's tincture is the most powerful and preferably the method of medication. The doses, of course, are very small and the treatment is therefore comparatively safe. Another point of importance in the treatment of children is that it is pleasant to take.

45. **The Union of the Recti in Abdominal Ptosis.**—MacKellar reports a case of pronounced gastroptosis and nephroptosis of the right kidney in which the recti abdominales showed marked distinct diastasis. The operation to relieve the condition was the splitting of the sheaths of the recti muscles on the anterior surface and uniting the two in one sheath by suturing the sheath on the posterior and anterior side of the two enclosed muscles. The patient made a good recovery and passed through her pregnancy without any separation of the parts, and the visceral ptosis has remained practically cured.

46. **Musical Murmurs of the Heart.**—The opinions of authorities are first given by Trent, who then reports a case in which there was a continuous loud musical murmur of the heart from over the cardiac region with the greatest intensity about the mid-sternum on a level with the third costal cartilage. The sound was constant and so loud that it troubled the patient at night, keeping him awake, and other members of the family were also disturbed by it. It resembled the cooing of a dove. The man died suddenly; the post-mortem showed aortic insufficiency to a very marked degree, which was the cause of death. From this and the literature on the subject the author concludes that musical murmurs of the heart are freaks and are important simply as indicating serious organic lesions, and interesting only because of their rarity.

47. **Hyperchlorhydria.**—The points made by Graham in this article are the frequency of the condition and its easy diagnosis by the stomach-tube, and the importance of determining whether or not we have a primary or secondary hyperchlorhydria, and treating for the removal of the predisposing cause.

52. **Bacteriology of the Stomach.**—Kellogg's article reports the findings of bacteriologic examinations of the stomach fluid in various conditions, and his conclusions are summarized as follows: 1. A healthy stomach does not require the aid of germs in the digestion of foods. 2. Sterile food is digested in the healthy stomach without the development of bacteria or other micro-organisms. 3. Neither free hydrochloric acid nor combined chlorin, even when present in excess, is a certain means of sterilizing the gastric contents. 4. The gastric contents may be found sterile after a sterile test-meal in cases in which free hydrochloric acid is entirely absent and the proportion of combined chlorin small. 5. Fruits, especially fresh fruits, and fruit juices, are capable of completely sterilizing the stomach when used in sufficient quantity.

53.—This article has appeared elsewhere. See The Journal, xxxv, title 12, p. 1657.

60. **Bone Shaft Fractures.**—Manley reviews the subject of fractures of the long bones and summarizes his conclusions as follows: 1. The nearer the fractures of the bone shaft are located to the joint the more serious the result. 2. When complicated by subluxation, or when the fracture extends into the articulation, troublesome complications are quite certain in a large proportion of cases. In this class the osseous lesions may be non-important as compared with the change to the articular structures, large blood-vessels and nerves. 3. The symptoms of joint fracture are not unequivocal. There are no special characteristic symptoms in the pain of luxation, sprain or fracture. As a rule, after reaction sets in the suffering is greater in joint than in any other fractures. 4. The definite diagnosis of position and quality of intra- and extra-articular fractures is often difficult and sometimes impossible. When the fragments are not displaced, the application of great force under anesthetics to verify the diagnosis is unjustifiable unless the patient insists on it. In consequence of the frequent errors and uncertainties of the use of the X-rays without other confirmatory evidence their employment as diagnostic agents in these doubtful lesions is unreliable. 5. The primary treatment of closed intra-articular fractures or those in close proximity to the joint in general must be recognized on these fundamental principles everywhere. In intracapsular fractures at the hip, with proper antiseptic precautions, primary resection of the distal fragments will shorten convalescence, spare the patient needless suffering and leave a better limb than when the articular head is retained. 6. In a considerable proportion of aggravated cases in young persons, consecutive osteoplastic surgery will frequently give the

best results. This is only resorted to after acute symptoms have subsided.

61. **Intermittent Hydrops of the Knee.**—Cale reports a case of this condition, which he regards as a rare condition. One patient will have an attack occurring every eight days; another, occurring every eleven days, etc. In individual cases we rarely see any irregularity in the time of recurrence. Another peculiarity is that it disappears during pregnancy. He finds no mention of it in American text-books. He is inclined to consider it as possibly due to infection by some micro-organism having a regular cycle of life within the period of its occurrence.

63.—See abstract in THE JOURNAL, xxxv, p. 1048.

69. **Multiple Fibromata.**—Preble and Hektoen report very elaborately the post-mortem findings and pathologic examination of multiple fibromata in a case of arthritis deformans. They remark that the case is an extreme degree of a not uncommon condition, that of generalized neurofibromata, which is rather of more than ordinary interest because it presents certain rare if not unique features from the joint disorder and trophic changes in the skin. The general subject of neurofibromata is discussed. In this case besides the joint affections, which were those of well-marked arthritis deformans, there was ulceration similar to perforating ulcer of tabes, and the spontaneous gangrene of one foot was looked upon as also of trophic origin connected with the general condition.

70. **Cholelithiasis and Pancreatic Disease.**—The object of this article is to direct attention to the occurrence of pancreatic disease as a complication of gall-stone colic, the method of its occurrence and the nature of the lesions that occur. The anatomy of the parts is described and a case reported where lesions of the pancreas were associated with impaction of the stone near the orifice of the common ducts. It is held that the primary cause of lesions in and about the pancreas in this case was the interference with the outflow of pancreatic secretion from a lodgment of calculus in the common duct, and in support of this view Opie has collected a number of cases from the literature in which there were lesions of the pancreas with necrosis of surrounding fat or both, and lodgment of the gall-stones near the orifice of the common duct, thus showing the similar etiology of the symptoms. The author says in conclusion that should the lodgment of the stone occur in this position where it may at the same time compress and occlude the duct of Wirsung and become impacted, there are cases reported to show that one or several conditions may result: 1. An individual, usually in fairly good health, with perhaps a history of previous gall-stone colic, is suddenly attacked with pain in the epigastric region, accompanied by vomiting and followed by collapse. Death follows usually within forty-eight hours, and at autopsy gall-stones are found in the bile-passages, while that one which caused the fatal attack may still be lodged in the common duct near its orifice. The pancreas, is enlarged, infiltrated with blood, and hemorrhage may have occurred into the surrounding tissue. Foci of fat necrosis are usually present. 2. A fatal termination may not follow rapidly the symptoms mentioned. Pain in the epigastrium persists, jaundice may be present, and a tumor mass above the umbilicus may indicate a probable lesion of the pancreas. At the end of one or more weeks or months death occurs, often with symptoms indicating the presence of suppurative inflammation, presumably in the neighborhood of the gland. At autopsy the diagnosis of cholelithiasis is confirmed by the presence of gall-stones in the gall-bladder or in the bile-ducts, and occasionally the offending calculus is still lodged near the junction of the common bile-duct and the duct of Wirsung. The pancreas is dry, black and necrotic, and evidence of previous hemorrhage may be present. Secondary infection has occurred and the pancreas lies in an abscess cavity formed by the bursa omentalis. In the wall, and often widely disseminated in the abdominal fat, are foci of necrosis. Since the individual has survived the primary lesion, opportunity has been given for the development of secondary changes in the injured pancreas and neighboring fat. 3. In certain instances long-continued or repeated obstruction of the pancreatic duct by gall-stones does not cause the acute lesion described, but produces chronic inflammatory changes.

72. **Asthenic Bulbar Palsy.**—Burr and McCarthy report an additional case to the few already known of this obscure disorder. They ask, in discussing the condition, where is its locality and what is its nature. The morbid anatomy is at fault here and we are obliged to fall back on general physiologic and pathologic laws and draw inferences from analogous affections. They think there is little direct post-mortem evidence in favor of the bulb as the seat of disease. The slight changes that have been found were in it and the cranial nerves. While they are insufficient to cause the symptoms they may indicate the action of the toxins. The symptoms certainly point toward the bulb as the part first and most seriously affected. They conclude, considering everything, that it may be said with comparative safety that the affection is one of the lower motor neurons, but whether the cell bodies or the axons are the first and most affected can not yet be determined. Primarily the disease may be in the motor muscular end-plates. The disorder certainly looks like a toxic disease. It frequently follows some mycotic affection, and kills without visible wounds. In the case reported they are inclined to think that pregnancy had some positive influence. The patient was pregnant at the first onset, and again when the condition took a serious turn. The fact that pregnancy may seriously disturb metabolism in the kidney disorders, multiple neuritis, and the greater tendency of pregnant women to certain diseases is well known. In this case the smallness of the bulb, which was developmental not secondary, might have had some influence. What nervous elements were present were normal, but fewer than usual and may have been dynamically weaker. It is possible that the ill-developed bulb was unable to withstand the stress of pregnancy. The second case reported was that of a young woman who had complained of general neurasthenic symptoms and emotional disorders and dated her troubles from an attack of la grippe. With general weakness there was numbness of the limbs starting in the left arm and gradually extending. There was also slight vertigo, blurred vision, and occasional diplopia. The ocular muscles revealed nothing specially important excepting a constant right hyperphoria. There was a certain degree of facial paralysis which extended involving the entire side; excruciating pain in both ears, some trouble in hearing and a suggestion of bulbar paralysis. After a few months, however, she completely recovered. As regards the treatment of asthenic bulbar palsy the authors say there is no specific. Electricity is dubious, massage is useful and arsenic is the one drug that seems to be of benefit.

73. **Gonorrheal Ulcerative Endocarditis.**—From a study of the cases reported, Lartigau offers the following conclusions: 1. Gonorrheal urethritis may be the starting-point for a fatal septicemia induced by a pure infection with the gonococcus. 2. Endocarditis and arthritis are occasionally complications of such an infectious disease. 3. The endocardial processes may be incited by the gonococcus without the association of other organisms.

74. **Obstructive Biliary Cirrhosis.**—Ford reports the literature of cirrhosis of the liver with special reference to the frequency of the type which seems to stand in etiologic relationship with pressure on the common bile-duct of an enlarged gland of the hilum of the liver. Some twenty-four cases are more or less briefly reported. Ford concludes his paper as follows: From the study of the cases of cirrhosis seen in Montreal, and from a review of the cases reported by other authors, together with the observations of experimental pathologists, we are justified in drawing a number of general conclusions: Complete obstruction to the flow of the bile in animals produces a cirrhosis of the liver, interlobular in character, of considerable extent, provided the animals are allowed to live a sufficient time after primary operation. This cirrhosis is due to the damming back of the bile per se, and not to the inflammation of the walls of the smaller bile-channels. In man, complete obliteration of the bile-ducts caused by pathologic changes leads to cirrhosis of the liver which can not be explained simply by damming back of bile, but must be considered to have, as an

added etiological factor, that inflammation of the walls of the biliary channels which is invariably present. The type of the cirrhosis of the liver seen in man subsequent to obstruction of the bile-passages can not be differentiated anatomically from the type of liver seen in Hanot's hypertrophic cirrhosis with jaundice. The symptom-complex of obliterative cirrhosis is so absolutely different from Hanot's cirrhosis in the variety of its symptoms and in the frequency with which they occur as to justify the statement that obstructive biliary cirrhosis is a distinct morbid condition quite apart from any other variety of cirrhosis of the liver.

75. **Dorsal Dislocation of the Trapezoid.**—Sheldon reports a case of this rare condition, and reproduces the account of the only other case—that of Gay—which he has been able to find in the literature. After discussing the anatomy of the condition he thinks it probable that in Gay's case and in the one that came under his own care there was a congenital weakness or absence of the ligaments or a mal-development of the carpal bone or a combination of these conditions, which rendered an uncomplicated dorsal dislocation of the trapezoid possible.

80. **Vaginal vs. Abdominal Hysterectomy for Uterine Cancer.**—The advantages of each form of operation are discussed by Boldt, who finds vaginal hysterectomy has a smaller opening of the peritoneal cavity, greater rapidity of operation, less shock, more rapid convalescence, avoidance of abdominal wound, and lessening of direct mortality. The objection that one must work in the dark does not hold good excepting when the bladder is separated from the cervix and then the work can be kept within sight to a great extent by proper use of retractors. The advantage of abdominal hysterectomy is that it permits more extensive removal of the lymphatic and surrounding glands. The only case where its use is at present indicated according to his view is where the uterus is too large or too adherent to be removed by the vagina without morcellation and those cases where the diagnosis of glandular enlargement is made.

81.—See abstract in The Journal, xxxv, p. 1425.

82. **Uterine Irrigation.**—The treatment here suggested by Talley for chronic inflammatory disease of the uterus is irrigation with hot alkaline water, and he uses for this purpose a narrow canula provided with two wires so as to allow the return flow of irrigating fluid and permit the uterine canal to be washed to its entire extent. The canula is curved at its end to provide for easy introduction, perforated in every direction at its extremity and of such a size that it will easily pass through a No. 15 French catheter scale. It is attached to a fountain syringe of at least two quarts' capacity and a thermometer should be used to determine the temperature of the water. He has also used a speculum with a funnel through which the return fluid may pass without danger of wetting clothing or bed. The solution used is water with 1 dram of bicarbonate of soda to a quart and enough carbolic acid to render it mildly aseptic. He never has the temperature above 123 F. and usually somewhat less; about 110 at the beginning and gradually increasing it. It is important that the irrigation should be carried on until its secondary vasomotor effects are insured. Cases amenable to this form of treatment are those in which the cervical canal is patulous.

83.—See abstract in The Journal, xxxv, p. 1501.

85. **Proctorrhaphy.**—Noble reports three cases in which he operated by fixation of the rectum to the abdominal wall in case of prolapse of that organ. The operation he proposes is to open the peritoneal cavity by an incision made through the left rectus muscle slightly below the promontory of the sacrum, to search for the sigmoid or for the rectum and make traction upon it until it is inverted and the "slack" has been taken up. The point at which the lower portion of the rectum will come in contact with the abdominal wall on slight tension should be determined and this point attached to the abdominal wall by three or more fine silk sutures passed so as to include a portion of the rectus muscle and should pass under the anterior longitudinal band of the rectus. In this way the bowel can be firmly attached with less danger of penetrating its cavity and with the best prospects of producing permanent effects. The abdominal wound should then be closed by the tier method.

93.—This article has appeared elsewhere. See The Journal, xxxv, ¶98, p. 1511.

94.—See abstract in The Journal, xxxiv, p. 1338.

95. **Marchand's Adrenals.**—Warthin reports the case of an adrenal body found in the broad ligament, with its structural and microscopic examination, and discusses to some extent the literature. Noticing Aichel's paper, he adopts his suggestion to call these growths "Marchand's adrenals," since Marchand was the first to observe and describe them. He says in conclusion: It may be said that while Aichel's results need further confirmation, it is very probable that his view is the correct one, and that adrenal tissue is a normal constituent of the broad ligament. The practical importance of this is very great, and not only to the physiologist and pathologist, but to the clinician and gynecologist as well. Without doubt we have in Marchand's adrenals certain anatomical elements which may explain pathological conditions of the broad ligament and testis heretofore enveloped in mystery. Many tumors and cysts of these regions, whose origin is now unknown to us, may be shown by future observation to be derived from these little organs.

97.—See abstract in The Journal, xxxv, p. 1424.

98. **Sexual Feeling and Removal of Ovaries.**—In the case reported by Smith there were misplaced and inflamed ovaries causing the patient misery, with complete absence of sexual feeling. The ovaries were removed, as the patient had been under medical treatment for years without benefit. The result was restoration to health and complete restoration of sexual feeling, which had heretofore been absolutely absent. The cure seems to be permanent and he agrees with Lawson Tait that in cases of useless and diseased ovaries the removal of the diseased structure restores the normal conditions and does not unsex the woman.

107. **Lupus Vulgaris.**—Everett Smith reports a case of lupus of fifteen years' standing cured by application of the X-rays. A mask was made of sheet lead for the face, with a hole over the diseased portion, and this was exposed to the X-ray about every fifth day for about twenty minutes at a time, the surface being placed two inches from the light. In all, twelve treatments were given, and no medicine was used, even vaselin was denied him. After the second treatment healthy granulations appeared and healing was rapid.

108. **Cholelithiasis.**—Eugene Smith discusses cholelithiasis from the surgeon's point of view, reporting two cases to illustrate his points. He sums up the indications for operative treatment under two headings: In the first place, operate for biliary calculus obstruction along the bile-tracts which has in its train of sequelæ recurring colic, hydrocholecyst, persistent jaundice and cholemia; in the second place, operate for sepsis of the bile-tracts when it develops such dangerous conditions as suppurative cholangitis, suppurative cholecystitis or perforation of the duct or cholecyst. In both classes suffering and death are to be dreaded in the majority of cases more from the disease and its sequelæ than from the surgeon's knife.

116.—See abstract in The Journal, xxxv, p. 447.

117.—Ibid., p. 578.

121. **Incised Wounds.**—The method described by Bretz for coapting superficial incised wounds consists in fixing a piece of adhesive plaster on either side of the wound after thorough cleansing and putting the suture through the plaster instead of through the tissues themselves. In this way he thinks better coaptation is obtained than when it is put through the skin, is less painful; it avoids stitch-hole abscess, prevents stitch-marks, and there are no stitches to pull out. He illustrates the method for various forms of wounds.

132.—See abstract in The Journal of June 2, p. 1416.

133.—This article has appeared elsewhere. See The Journal, xxxv, p. 267.

135. **Iodized Starch.**—Solomon recommends the use of

iodized starch made by triturating 5 parts of iodin in a small quantity of water with 95 parts of starch slowly added and carefully rubbed until the mixture is regularly and uniformly a blue-black. It is slowly dried at a temperature not higher than 140 and carefully rubbed into a fine blue powder. We then have a 5 per cent. iodized starch, insoluble in water, with characteristic iodin taste and slight odor. It should be kept in glass-stoppered bottles. He has used this whenever iodin is indicated and thinks its action is prompt and in the proper dose energetic. The dose recommended by some authorities is, he thinks, too small. He has found from 3 to 10 grs. in capsule, pill or powder necessary to produce the desired effects. Its advantages are that it is physiologically an active preparation for both external and internal use and free from the irritation and caustic action of most of the iodin preparations. It is not objectionable to the senses and is stable enough to be kept indefinitely with reasonable care.

148. **Dentigenous Cysts.**—Cobb reports cases of this anomaly and concludes that the cysts are not, as Albarran suggested, due to epithelial secretion from the cells of the gubernaculum dentis, but rather, as Dr. Edward Briggs believes, an inflammatory process originating about the diseased teeth, which is characterized more by excessive secretion than by active destruction. The prognosis is also of interest, as he would not believe that so large a bony swelling as occurred in his cases would subside in so short a time. From this series he thinks dental disease can be eliminated and operation avoided. The salient points of treatment are free drainage and careful dental treatment.

154.—See abstract in THE JOURNAL, xxxv, p. 1425.

FOREIGN.

The Lancet, December 29, 1900.

Calcium Iodate as an Iodoform Substitute and Gastro-Intestinal Antiseptic. WILLIAM MACKIE.—After first noticing the work of Sonstadt in regard to this drug, the author gives the theory of its action as an antiseptic. It is an iodin compound containing 51 per cent. of iodin, and in addition 16 per cent. of available oxygen. On contact with putrescible organic matter, whether in acid or in alkaline media, it slowly liberates iodin. In alkaline solution, while the organic matter is being oxidized by the oxygen set free from decomposing iodate, the iodin by a reaction well known to occur in alkaline media slowly re-forms iodate, through the decomposition of water. The iodate so re-formed in contact with another portion of putrescible matter yields further proportions of free oxygen and iodin to act as before, and so on. The process is, therefore, a continuous one. As most pathologic discharges are alkaline we have in such cases the necessary conditions for the continuous action of the iodate. In acid media in the presence of reducing substances iodin is liberated and by the decomposition of water sets free oxygen, which is used up in oxidizing any unstable organic compound which may be present. The iodin in these cases passes into hydriodic acid or an iodid, and so eventually ceases to act. If, however, the acid is hydrochloric, as in the gastric juice, chlorin is liberated in the greatest abundance. Chemical equation shows that calcium iodate in contact with hydrochloric acid liberates nearly four-sevenths of its weight of chlorin, and on this fact its use theoretically as a gastrointestinal antiseptic is based. Something no doubt depends on the chemical instability of iodates generally, and on this one in particular, on the nascent action of the liberated products, and in this case that the base forms insoluble compounds such as carbonate and phosphate in contact with alkaline discharges, thus probably facilitating the free operation of the acid radicle, and on such its particular virtue depends. It would appear, therefore, that calcium iodate acts more as a destroyer of the products of bacterial life than as a bactericide. Mackie thinks, however, that its inhibitory power on bacterial growth can not be questioned, and it thus closely conforms to iodoform in its action. The function of the salt as a deodorant can be easily understood as a result of its chemical action. Iodates decompose sulphuretted hydrogen, precipitating it in part as sulphur, in part oxidizing it into sulphuric acid. The substance is easily prepared by any chemist by mixing iodin in a solution of potassium iodid with bleaching powder and washing with cold water. It is a white powder without taste or smell, soluble in 390 parts of water. Even in this solution, however, it is a powerful antiseptic, which he shows by reporting experiments similar to those made by Sonstadt. A piece of meat, for instance, was suspended in a saturated solution of the salt and found perfectly fresh at the end of a fortnight. A few grains of the dry salt thoroughly deodorized very fetid pus, etc. Cases are reported by the author, of fetid breath, septic wounds, discharges of ulcers, otorrhea, abscess, etc., treated successfully with this drug. He has also used it in cases of septic bladder, with advantage in all and perfect cure in at least one, also as a vaginal douche and for chronic urethritis. Speaking generally he says calcium iodate has been used in almost all cases where iodoform is commonly used. He has not, however, applied it to cut surfaces of amputation flaps, though he has in several cases powdered the sutured edges after minor operations for diseased conditions. In all operations where the surfaces are left to granulate he has used it by dusting the dry powder on the surfaces, and in no case has there been any irritating or toxic action. Even children do not complain of any smarting after its use. Its advantages as compared with iodoform may be summarized as absence of smell, checking of fetor, prevention of hyper-granulation, and the inhibition of undue formation of pus. It can be used, moreover, where iodoform is inadmissible, in gargles, washing out the bladder, etc. Internally he can testify to its efficiency in checking fermentative gastric changes. He has frequently taken 2 grains and sometimes repeated the dose twice and even a third time during the day without any inconvenience, and always with marked relief. It leaves a slight metallic taste in the mouth for a little while, but this is not observed after repetition. On the day after a dose of 2 grains there is a feeling of general well-being and increased appetite, and for this reason he is inclined to think that it has some tonic properties. Sonstadt took as much as 15 grains at one time with a very slight headache the next day, and such effects as might ordinarily follow a dose of quinin. Mackie would prefer to give the drug in solution, as he has noticed a feeling of heat in the epigastrium after swallowing the dry salt. Sonstadt's maximum dose of 15 grains is a long way in advance of any possible requirement. Three or four grains may be given as a fair average for the adult.

Circumcision as a Preventive of Syphilis and Other Disorders. E. HARDING FREELAND.—The writer argues for circumcision as a preventive of syphilis, showing statistics from Hutchinson and others giving reasons why this should be effective. He thinks that in the ordinary operation too much is left and too little is removed, and the protection in this regard is therefore lost. He would also advise, with the thorough removal of the prepuce, taking away a wedge-shaped piece of frenum and thus obliterating the folds which exist on its side. He believes that if the practice were general a great and lasting benefit would be induced.

On a New Method in the Discission of Soft Cataracts. PERCY DUNN.—This writer advises in the treatment of soft cataracts by discission to avoid increased tension by draining away the aqueous before withdrawing the needle. It is reasonable, he says, to conclude that the condition of the lens after the needling would determine the degree of restored tension. With a swollen lens the aqueous would probably only be re-secreted to the amount needful to restore the normal tension, and he does not think it possible to conceive that the glaucomatous symptoms could arise under these circumstances. Another advantage of the method is the possibility of freely breaking up the lens, and still another, the rapid absorption of the soft lens matter. A lowered tension implies a more rapid circulation of fluid through the eye and is exactly the condition of affairs to be most desired for rapid absorption. He reports a case in which he carried out these methods with the best results. The only possible untoward complication that could ensue is that of iritis originating from mechanical irritation caused by the presence of broken-up lens matter, but the doctrine that mechanical irritation *per se* can excite inflamm tion anywhere in the tissues is not one which at the present day receives support of scientific testimony. In senile cataract no difficulty is experienced in obtaining a fairly rapid absorption of the lental débris which it has been found impossible to remove after extraction of the lens, a result which he thinks is chiefly due to lowered tension in the eye caused by the necessary steps of the operation in this case.

Indian Medical Gazette, December, 1900.

The Cause of Beri-Beri. E. R. Rost.—From a suggestion in an article in the *British Medical Journal* of the connection between rice and beri-beri, Rost examined various rice waters and liquors and found one organism in all which is also found in damp rice, and in the prolonged examination of the blood of a beri-beri patient the same peculiarly shaped organisms were noticed. They were also later found in the cerebrospinal fluid, serous exudation, and in the sheath of the sciatic nerve on post-mortem. Cultures in sterile rice broth, beef broth, in blood, hydrothorax fluid and ascitic fluid were made and the morphology of the organism was observed. It is a diplobacillus, generally seen as an angular organism, developing by spores. Double dumb-bells are seen as well as single knobs or rods; it is easily stained by carbol-fuchsin. It multiplies with great rapidity, will grow best in rice broth, ascitic fluid and hydrothorax fluid, and with difficulty or not at all on solid media, except coagulated blood-serum. It was found that it can withstand a temperature of eight hours at 220 F., but after the ninth hour the cultures gave negative results. Sterilization for long periods is therefore necessary. He has found this organism in 32 cases of beri-beri in the blood. In rice it's appearance is that of a fibroid clammy coating sticking the granules together. He thinks rice-eating, and especially drinking rice liquor, is the principal cause. The most important point, he remarks, is its vitality, which calls for a better method of cooking rice than is often employed.

Presse Medicale (Paris), December 1, 22 and 26.

Rennet Ferment in Gastric Juice. L. Meunier.—Investigation of the rennet ferment in the gastric juice of forty-two individuals in various pathologic conditions showed a striking coincidence between the clinical prognosis and the amount of rennet action in the gastric juice. The rennet also affords valuable information in regard to the secretion of the gastric mucosa in the same way as the pepsin, while the tests are much easier than for the latter.

December 22.

Is the Bacillus Coli Agglutinated by the Serum of Typhoid Patients? P. Courmont.—The results of tests on twenty-five typhoid-fever patients showed that the bacillus coli, as a rule, was not agglutinated by their serum at any stage of the disease. When agglutination occurred it was very feeble, no more than is frequently observed in normal blood, and not at all proportionate to the intensity of the agglutination of the typhoid bacillus.

December 26.

Lavage and Ferric Chlorid in Treatment of Round Ulcer. R. Romme.—Bourget is not an advocate of surgical treatment of all cases of round ulcer. He thinks that good results can be attained by resting the stomach, diminishing the secretion of the irritating gastric juice, and aiding cicatrization with ferric chlorid. He accomplishes this by lavage of the stomach every other day with a 2 per cent. solution of ferric chlorid, supplemented by the administration of sodium bicarbonate in a 3 per cent. solution two or three times a day, three or four hours after meals, in amounts sufficient to neutralize the acidity of the gastric juice. He does not approve of rectal feeding, as it does not afford sufficient nourishment and as the secretion of the acid gastric juice continues. He also rejects milk and directs his patients to eat nothing but rice boiled in water with a little salt for one to two hours until it is a syrupy fluid. Later the water is replaced by milk: 50 gm. rice in a liter of milk, sweetened or salted, allowing about 200 to 300 gm. of the mixture at each meal, which, weight for weight, is as nourishing as white meat. The chief symptoms vanish in eight or ten days and a mixed diet can be allowed five days later, the sodium bicarbonate being continued.

Surgery of the Sympathetic for Neuralgia. J. Termier.—This is a recent Lyons thesis, inspired by Jaboulay, which reports the favorable results obtained in a number of cases of severe pelvic neuralgia, sciatica, etc., by resection of the sympathetic at various points. The operation most frequently practised was "décollement" or detachment of the rectum, which ruptures the sympathetic fibers connecting with the sciatic nerve. It was successful in curing several cases of neuralgia of this nerve and of different vasomotor disturbances of the lower members; also in a case of ataxia, in which the lightning pains were permanently abolished by it. Termier attributes the primal cause of a number of neuralgias to the ganglionary system and suggests discission of the peri-aortic fibers of the solar plexus in abdominal neuralgia and other affections possibly dependent on the abdominal sympathetic. He reports a number of cases of facial neuralgia cured or very much improved by resection of the cervical sympathetic.

Revue de Chirurgie (Paris), December.

Exclusion of the Intestine. F. Terrier and A. Gosset.—In this portion of the article, concluded from the August and November numbers, fifty-two cases of exclusion of the intestine are reviewed or described at length, with forty-four recoveries. Total occlusion of the excluded loop seems to be unanimously rejected now and exclusion with partial occlusion of the excluded loop is given the preference in cases of stercoral fistula or tuberculosis of the intestines. It is still a question whether in case of cancer which it is impossible to extirpate, unilateral exclusion is the best method of procedure, also whether the reflux of intestinal contents into the excluded portion is really to be feared.

Special Process for the Radical Cure of Inguinal Hernia. A. Le Dentu.—The method described by Le Dentu has been thoroughly tested by him during the last ten years and was the first of the "fold-operations," the second being Ricard's fold taken in the fibrous capsule of the shoulder-joint in case of recurring luxation and the third Le Dentu's application of the process to the knee. The simplicity and facility of the operation are great advantages, and also the fact that it is easier to secure the adhesion of broad flat surfaces than of narrow edges. The essence of the process is the loosening of the abdominal wall by inserting the finger beneath the external oblique and its aponeurosis after the hernia has been reduced and the sac taken care of. The abdominal wall is stretched by the forefinger until it forms a recess above the spermatic cord like the finger of a glove. A row of U-shaped stitches are then taken perpendicular to the axis of the fold thus raised, and when tied they reconstitute the wall with a double fold of muscle and aponeurosis. In case of extensive adhesions it may be necessary to split the fold down the center, otherwise proceeding as above. He uses catgut or silk, but observes that removable sutures of wire, if preferred, would probably answer the purpose equally well. He does not cite any cases, merely remarking that his results will bear comparison with those of other methods.

Cancer of the Large Intestine, Rectum Excepted. R. De Bovis.—This comprehensive study is concluded from five preceding numbers with a detailed description of nineteen unpublished cases and a number reported in Russian, Scandinavian and Dutch journals. In the first of the three personal cases there was a history of chronic constipation for two years, but no obstruction, diarrhea, nor blood nor pus in the discharges. When the patient, a woman of 57, entered the hospital, there had been obstruction for five days and vomiting, not fecal in character. The patient was much emaciated and there were considerable distension of the abdomen and tenderness in the right iliac fossa, which seemed a little fuller and less resonant than other portions of the abdomen. The intestine was retained outside of the abdominal cavity by a glass rod passed beneath it. The patient died, apparently from autointoxication. A small flat piece of bone had lodged on the stricture, which proved to be a small ring cancer of the sigmoid flexure. In another case, a robust man of 66, of good personal and family history, had symptoms of obstruction for eight days without vomiting. The abdomen was distended, particularly on the left side, but nothing morbid could be discovered before operating. The patient died from the results of an abdominal stercoral phlegmon, and on autopsy a small ring cancer, a scirrhus, was found as in the first case, at the sigmoid flexure. The distended loop had been held merely by a strip of gauze, which had allowed it to subside, thus favoring the production of the phlegmon. In a third case the patient regained comparative health after an artificial anus had been made in the sigmoid flexure. The evidence, however, was conclusive in regard to the existence of a lesion similar to the others—a cylindrical epithelioma—although the anatomic proof was lacking.

Semaine Medicale (Paris), December 19.

The Heart in Chlorosis. E. BARIE.—The palpitations, pain in the precordial region and false angina pectoris noted in neuro-arthritic or dyspeptic patients are merely functional disturbances common in chlorosis. The cardiac thrombosis and dilatation of the heart occasionally noted are more serious. In five cases recently observed by Barié the heart was unusually small. Hypertrophy has been noted by many clinicians, and also a false hypertrophy due to the displacement of the diaphragm, which pushes back the heart, as can be differentiated by fluoroscopy. When actual dilatation exists it is probably due to atony of the myocardium from defective nutrition, the adulterated blood not supplying the necessary elements, although Wybauw suggests that it is due to a general infiltration of the tissues by the diffused serum of the blood. He points out that the quantity of the urine increases, while the weight diminishes, when recovery commences. Virchow has suggested that the dilatation may be secondary to a specially narrow aorta, but in this case the lesion would persist. One of the features of chlorotic dilatation is its transient character. In case of dyspepsia the gastric disturbances are liable to cause a reflex action which is transmitted by the great sympathetic to the capillaries of the lungs and incites them to spasmodic contraction. This raises the blood-pressure in the pulmonary artery and hence the right ventricle dilates, sometimes to such an extent that functional tricuspid insufficiency is the result. This, in turn, is liable to produce a souffle at the apex, spreading distinctly toward the left axilla, strictly systolic and not modified by the position of the patient. On the other hand, if the souffle is weak, if it is above, either to the right or left of the apex, if it does not spread, if it occurs in mesosystole, and especially if it alters as the subject stands or reclines, it is a cardiopulmonary souffle—a sound occurring in the lung—rendered rhythmical by the movements of the heart.

Surgical Prothesis With Injections of Paraffin Into the Tissues. R. GERSUNY.—The first time this method was tried was on a man who was seriously depressed from the mutilation following an operation for tubercular orchi-epididymitis. Gersuny injected 8 c.c. of sterilized "white vaselin"—which is a mixture of solid and liquid paraffin, melting at 40 C.—into the left half of the scrotum and a fortnight later about the same amount into the right half. A fortnight later 3 c.c. were injected into the left half and 2 c.c. into the right. The result was extremely satisfactory. The scrotum presents the normal aspect as when contracted by cold, and on palpation the two round bodies on each side, of a hard consistency, simulate to perfection the missing testicles. This success encouraged him to inject paraffin into the uvula and velum of the palate in two persons who had been operated on for hare-lip, but were unable to articulate the syllable "ga." The parts were increased in size by the paraffin until the disturbance completely disappeared. In a case of incontinence of urine after an operation for a vesico-vaginal fistula, the function of the sphincter was restored by injecting a ring of paraffin around it. The paraffin does not change nor become absorbed and thus forms a permanent subcutaneous prothesis. He suggests that it may prove useful in raising sunken cicatrices, in correcting deformities after ablation of subjacent bone—the superior maxillary, for instance—and to supply a base to flattened noses and breasts. It may even prevent ankylosis if injected between the surfaces of the bones in operations on the joints, and can be removed later when a fibrous capsule has formed. Perivascular injections may arrest venous stasis and thus prevent varices, and hernia might also be controlled by appropriate use of paraffin in this way.

Centralblatt f. Chirurgie (Leipsic), December 22.

Sterilization of Sponges Without Injury. C. A. ELSBERG.—Applying to sponges the principles of his method of sterilizing catgut without injury, Elsberg states that they can be boiled for hours without losing any of their porosity, elasticity, softness or diminishing in size. He first cleanses them by soaking for twenty-four hours in an 8 per cent. solution of hydrochloric acid, which is afterward thoroughly washed out. They are next boiled for five to ten minutes in a solution of ten parts caustic potash and twenty parts tannic acid in a thousand parts water. They are then rinsed in sterile water or a solution of carbolic acid or sublimate until all traces of the brown potash solution have vanished, after which they are kept in a 2 to 5 per cent. solution of carbolic acid until needed. Large sponges infected with staphylococci, streptococci, anthrax and other bacilli and spores were always found sterile after boiling for even less than five minutes, in the potash and tannin solution, while they will bear repeated boiling without injury if the directions are followed.

Muenchener Med. Wochenschrift, December 4 and 25.

Advantage of the Curved Sound in Cases of Tumors of the Esophagus. H. STARCK.—The diverticulum sound has been found extremely useful at Erb's clinic in case of tumors of the esophagus. It penetrates where it is impossible to insert a straight sound. By turning it around, the tip constantly explores the periphery and finally locates the constriction and finds a passageway. An ordinary Nélaton catheter with a wire guide is curved at an angle of 180 degrees about 1.5 to 3 cm. from the tip. When this pathfinder has located the passage, larger sizes can be used and the lumen stretched until natural feeding can be instituted in some cases, or if not, a sound can be introduced for artificial feeding.

Significance of Alcohol in Disinfection of the Hands. E. BRAATZ.—The presence of air in the pores of the skin impedes the entrance of disinfecting fluids. Alcohol decomposes air ten times more rapidly than water, and hence allows the penetration of the fluids into the depths of the pores and crevices.

Success of Atropin in Intestinal Disturbances. P. OSTERMAIER.—Several writers have lately called attention to the advantages of subcutaneous injection of atropin in ileus and other intestinal disturbances. Ostermaier details several convincing observations, the result of a large experience with this remedy in cases of secondary reflex spasm or paresis of the intestines after calculus colic, lumbago, traumatism, etc., also in a few cases of appendicitis. He injects 1 mg. sometimes in two doses. The subjective disturbances rapidly disappear and in twelve to thirty-six hours a normal evacuation follows. Batsch reports one instance in which he injected 12 mg. in a few days in a case of intestinal perforation after difficult delivery. Boeck states that a fatal termination is rare even after taking 5 cg.

December 25.

Suprarenal Tablets in Addison's Disease. P. EDEL.—The first symptom of the disease was a sensation as if the region between the shoulder-blades was being pressed down and forward. Progressively increasing weakness was noted and the patient, a locksmith, hitherto healthy, was unable to work even for an hour a day. No remission had been observed at any time when the patient was first seen, six months after the first manifestations of the disease. In two or three days after the organotherapy had been instituted improvement was marked and in fourteen days the patient resumed his occupation. The pigmented patches also faded to their normal color and only traces of them around the eyes were still visible by the end of five weeks. The patient's manner of life was not altered in any way from usual during treatment. The autopsy, after a brief, intercurrent fatal tubercular meningitis, disclosed indications of quite general tubercular glandular lesions, including a nodule in the right suprarenal the size of a bean. The solar plexus and semilunar ganglion were imbedded in fibrous connective tissue.

Tubercular Peritonitis. R. Oehler.—It was possible to follow to date 39 out of the 44 patients with tubercular peritonitis treated at the Frankfurt clinic during the last five years. The participation of the umbilicus is the most reliable sign of the affection, in addition to the evidences of persisting ascites and cachexia. Out of the 39, 18 have died and 21 are alive and well to-day. It chiefly affects children, and death ensues in about half the cases, generally from meningitis, but otherwise from exhaustion and general debility, in the course of six to twenty-four months. In a large number of cases—51 per cent.—spontaneous recovery occurred in the course of one to two years.

Wiener Klin. Wochenschrift, December 20.

Difference Between Natural and Artificial Feeding of Infants. T. Escherich.—Is it possible, Escherich queries, that mother's milk contains some unknown substance which stimulates metabolism? This assumption would explain the inconsistencies observed and the results of natural feeding which in some cases indicate an almost specific reaction of the infantile organism to the mother's milk. The presence of such a ferment in mother's milk would include the child in the mother's metabolism somewhat in the same way as during placental circulation. It renders futile all our present efforts to approximate mother's milk in artificial feeding, but opens a path for future research which may yet lead to important results.

Tidsskrift f. d. Norske Laegef. (Christiania), December 15.

Retention of Urine from Retroversion of Uterus. E. Mo.—A woman of 45, ii-para, found micturition becoming painful and finally complete retention followed. The uterus was found in retrodisplacement and the urinary troubles ceased as soon as the organ was straightened.

Brazil-Medico (Rio de Janeiro), October 22.

Sero-Diagnosis of Yellow Fever. E. Meirelles.—This writer accepts the bacillus icteroides as the causal agent of yellow fever, and states that while it is very difficult to obtain the sero-reaction during the first stage of the disease, it can be obtained under certain conditions in the second stage and to perfection in the third stage, during convalescence and for a considerable time afterward. Dried blood serves as well as fresh, and old cultures are better than fresh. In a large number of patients with other infections it was impossible to obtain this specific sero-reaction for yellow fever. The prognosis may be based on the reaction to a certain extent, as the earlier it appears the milder the course of the disease in all his numerous tests.

Gazeta Med. Da Bahia, September, October and November.

Sodium Hyposulphite and Serum in the Plague. J. Penna.—Seventy-two patients were in Penna's care during the latest outbreak of the plague in Brazil, and he was much impressed not only with the benefits of serotherapy, but also of the subcutaneous injection of sodium hyposulphite in the vicinity of the bubo. His supply of serum was scanty and he was unable to administer the sufficient dose in many instances, but even with these drawbacks the mortality was only 19.3 per cent. among 36 patients treated with serum, excluding the moribund cases. The general mortality of the epidemic outside of the hospital was 50 per cent. He had found that a dog will bear the intravenous injection of 7 gm. of sodium hyposulphite in a 5 per cent. solution with no appreciable disturbance nor modification of the urine or corpuscles. He therefore ventured to administer it to man, injecting 1 gm. every three hours. Four died out of 20 patients thus treated, or 20 per cent., including one patient after thirty-one days of extensive gangrene of one of the buboes. The treatment was commenced from the first to the twelfth day of the disease in the fatal cases, death occurring the second, third, fourth and seventh day thereafter. The fever lasted an average of twelve days in the serum-treated patients, seventeen days in the 16 patients treated symptomatically and sixteen days in those treated with hyposulphite. The complete records of the cases of each group are tabulated, showing all the symptoms.

St. Petersburg Med. Woch., December 15.

Metastatic Choroiditis After Pneumonia. Germann.—During convalescence from a typical croupous pneumonia a purulent mestastatic irido-choroiditis appeared, with symptoms of meningitis and death in six days. Another fatal case is described in which croupous pneumonia was followed by endocarditis, embolic retinitis and panophthalmitis. Pure cultures of the diplococcus were derived from the anterior chamber. The only similar case described at length in literature was reported in 1892 by Herrnheiser, metastatic panophthalmitis with diplococci in the choroid, consecutive to croupous pneumonia, but Blessig, Eversbusch and Natanson have each observed a case of metastatic irido-choroiditis consecutive to influenza.

Vratch (St. Petersburg), December 15.

Mutual Relations Between the Bubonic Plague and Other Varieties of Hemorrhagic Septicemia. S. V. Konstansoff.—The writer's experimental research with hundreds of mice has established that preliminary active and passive immunization against hen cholera and swine plague due to the bacillus pestifer and bacillus suis, has no influence on the course of bubonic-plague infection. In the same way passive immunization against the bubonic plague does not affect the course of the infection from the above-mentioned coccobacilli. The absence of reciprocity between the immunization against bubonic plague and against the other varieties of hemorrhagic septicemia, indicates that the former has a special place apart in this group. He found antiplague serum a valuable differentiating means for the confirmation of bubonic plague. He also noted a marked contrast between even closely related forms of hemorrhagic septicemic infection in the faculty of resistance to a temperature of 45 C.

Books Received.

Acknowledgment of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

American Text-Book of Physiology. By Henry P. Bowditch, M.D.; John G. Curtis, M.D.; Henry H. Donaldson, Ph.D.; W. H. Howell, Ph.D., M.D.; Frederic S. Lee, Ph.D.; Warren P. Lombard, M.D.; Graham Lusk, Ph.D., F.R.S. (Edin.); W. T. Porter, M.D.; Edward T. Reichert, M.D.; Henry Sewall, Ph.D., M.D. Edited by William H. Howell, Ph.D., M.D., Professor of Physiology in the Johns Hopkins University, Baltimore, Md. Second Edition, Revised. Vol. XI. Muscle and Nerve; Central Nervous System; Special Senses; Special Muscular Mechanisms; Reproduction. Cloth. Pp. 551. Price, $3.50. Philadelphia and London: W. B. Saunders & Co. 1901.

A Handbook of Genito-Urinary Surgery and Venereal Diseases. By G. M. Phillips, M.D., Professor of Genito-Urinary Surgery and Venereal Diseases, Barnes Medical College. Illustrated by Half-tone Cuts and Special Drawings by L. Crusius, M.D., Cloth. Pp. 313. Price, $2.00. St. Louis, Mo.: Lewis S. Matthews & Co. 1900.

Proceedings of the American Pharmaceutical Association at the Forty-eighth Annual Meeting, held at Richmond, Va., May, 1900. Also the Constitution, By-laws and Roll of Members. Cloth. Pp. 968. Baltimore, Md.: Published by the American Pharmaceutical Association. 1900.

Thirty-second Annual Report of the Secretary of State on the Registration of Births and Deaths, Marriages and Divorces in Michigan, for the Year 1898. Justus S. Stearns, Secretary of State. Edited by Cressy L. Wilbur, M.D., Chief of Division of Vital Statistics. By Authority. Cloth. Pp. 155. Lansing, Mich.: Robert Smith Printing Co. 1900.

State Medicine and Sanitation. The Relation of the Illinois State Medical Society to Sanitation and the Regulation of the Practice of Medicine in the State. By A. C. Corr, A.M., M.D., Carlinville, Ill. Paper. Pp. 40. Carlinville, Ill.: Macoupin Printing Co. 1900.

Transactions of the Medical Association of the State of Alabama. (The State Board of Health.) Organized 1847—Meeting of 1900. Montgomery, April, 17-20. Cloth. Pp. 564. Montgomery, Ala.: Brown Printing Co. 1900.

Proceedings of the Fifteenth Annual Meeting of the Conference of State and Provincial Boards of Health of North America. Atlantic City, June 1 and 2, 1900. Paper. Pp. 118. Providence: Snow & Farnham. 1900.

Proceedings of the Philadelphia County Medical Society. October, November. Paper. Philadelphia: Published by the Society.

Report of the Surgeon-General of the Army to the Secretary of War for the Fiscal Year Ended June 30, 1900. Paper. Pp. 411. Washington: Government Printing Office. 1900.

Thirty-first Annual Report of the State Board of Health of Massachusetts. Cloth. Pp. 812. Boston: Wright & Potter Printing Co. 1900.

Transactions of the Michigan State Medical Society for the Year 1900. Volume xxiv. Cloth. Pp. 552. Detroit, Mich.: Published by the Society. 1900.

The Present Position of the Treatment of Simple Fractures of the Limbs. An Address Delivered in Opening a Discussion at the Meeting of the British Medical Association held at Ipswich, August, 1900. By William H. Bennett, F.R.C.S., Senior Surgeon to St. George's Hospital. To Which Is Appended a Summary of the Opinions and Practice of about 300 Surgeons. Reprinted, after revision, from the British Medical Journal, Oct. 7, 1900. Cloth. Pp. 41. Price, $0.80. New York and Bombay: Longmans, Green & Co. 1900.

On the Use of Massage and Early Passive Movements in Recent Fractures and other Common Surgical Injuries and the Treatment of Internal Derangement of the Knee-Joint. Three Clinical Lectures Delivered at St. George's Hospital. By William H. Bennett, F.R.C.S., Senior Surgeon to the St. George's Hospital Reprinted, after revision, from The Lancet. With 12 Illustrations. Cloth. Pp. 97. Price, $1.40. New York and Bombay: Longmans, Green & Co. 1900.

Refraction and How to Refract, Including Sections on Optics, Retinoscopy, the Fitting of Spectacles and Eye-Glasses, etc. By James Thorington, A.M., M.D., Professor of Diseases of the Eye in the Philadelphia Polyclinic and College for Graduates in Medicine. Second Edition. With 200 Illustrations, 13 of Which Are Colored. Cloth. Pp. 301. Price, $1.50. Philadelphia: P. Blakiston's Son & Co. 1900.

King's American Dispensatory. By Harvey Wickes Felter, M.D., Adjunct Professor of Chemistry, Pharmacy and Toxicology, and Professor of Anatomy in the Eclectic Medical Institute, Cincinnati, Ohio, and John Uri Lloyd, Phr.M., Ph.D., Professor of Chemistry, Pharmacy and Toxicology in the Eclectic Medical Institute, Cincinnati, Ohio. Entirely Rewritten and Enlarged. Eighteenth edition. Third Revision. In two volumes. Vol. II. Cloth. Pp. 284. Price, $4.50 per volume. Cincinnati, Ohio: Ohio Valley Company. 1900.

A Manual of Surgical Treatment. By W. Watson Cheyne, M.B., F.R.C.S., F.R.S., Professor of Surgery in King's College, London; and F. F. Burghard, M.D., M.S. (Lond.), F.R.C.S., Teacher of Practical Surgery in King's College, London. In seven volumes. Vol. IV. The Treatment of the Surgical Affections of the Joints (Including Excisions) and the Spine. Cloth. Pp. 370. Price, $3.75 net. Philadelphia and New York: Lea Brothers & Co. 1901.

Text-Book of Histology, Including the Microscopic Technic. *By Dr. Philip Stöhr, Professor of Anatomy at the University of* Würzburg. Third American, from Eighth German Edition. Translated by Dr. Emma L. Bilstein, Formerly Director of the Laboratories of Histology and Embryology, Woman's Medical College of Pennsylvania. Edited [illegible] ed Schaper, Professor of Anatomy, [illegible] 301 Illustrations. Cloth. Pp. 432 [illegible] P. Blakiston's Son & Co. 1900.

Experimental Research into the Surgery of the Respiratory System. An Essay Awarded the Nicholas Senn Prize by the American Medical Association for 1898. By George W. Crile, A.M., M.D., Ph.D., Professor of Clinical Surgery, Medical Department, Western Reserve University. Second Edition. Cloth. Pp. 114. Price, $2.50. Philadelphia: J. B. Lippincott Co. 1900.

A Guide to the Instruments and Appliances Required in Various Operations. By A. W. Mayo Robson, F.R.C.S., Senior Surgeon to the Leeds General Infirmary. Second Edition. Cloth. Pp. 62. Price, 2 s. 6 d. London, Paris, New York and Melbourne: Cassell & Co., Ltd. 1900.

The Essentials of Practical Bacteriology. An Elementary Laboratory Book for Students and Practitioners. By H. H. Curtis, B.S., M.D. (Lond.), F.R.C.S., Late Surgeon Registrar, University College Hospital. Cloth. Pp. 291. Price, $2.50. New York and Bombay: Longmans, Green & Co. 1900.

Comparative Physiology of the Brain and Comparative Psychology. By Jacques Loeb, M.D., Professor of Physiology in the University of Chicago. Illustrated. Cloth. Pp. 309. Price, $1.75. New York: G. P. Putnam's Sons. London: John Murray. 1900.

Transactions of the New Hampshire Medical Society, at the One Hundred and Ninth Anniversary, held at Concord, May 31 and June 1, 1900. Cloth, Pp. 333. Concord, N. H.: Ira C. Evans. 1900.

Medical and Surgical Reports of the Boston City Hospital. Eleventh Series. Edited by Herbert L. Burrell, M.D., W. T. Councilman, M.D., and Charles F. Withington, M.D. Pasteboard. Pp. 254. Boston: Published by the Trustees. 1900.

Change of Address.

F. P. Boyd, Chicago, to Lewiston, Minn.
W. W. Brown, Hebron, Ill., to Genoa Junction, Wis.
B. H. Burrell, Boston, Mass., to 1276 Logan Ave., Denver, Colo.
W. S. Bell, Bellaire, Mich., to Utica, Ohio.
R. K. Cole, Sedalia, Mo., to 151 W. 64th St., New York City.
S. T. Carswell, Fowlstown, Ga., to Luraville, Fla.
A. Cornelius, 489 W. Van Buren St., to 430 W. Randolph St., Chicago.
D. W. Craig, 356 Webster Ave., to 93 Sigel St., Chicago.
J. J. Clausen, Rialto Bldg., to 2311 Summit St., Kansas City, Mo.
J. A. Corn, City Hospital, to City Hall, Kansas City, Mo.
M. De Tar, Kansas City, Mo., to Kinsley, Kan.
L. Freeman, California Bldg., to 1843 Franklin St., Denver, Colo.
H. A. Gant, Water Valley, to Jackson, Miss.
H. A. Habenicht, 1934 Sherman Ave., to 1650 Tremont St., Denver, Colo.
R. N. Hall, 943 Madison St., to 339 Warren Ave., Chicago.
J. C. Hastings, 18 Bishop Ct., to 670 Monroe St., Chicago.
H. R. Johnson, Springerville, to Safford, Ariz.
J. B. Killebrew, 107 N. Conception St., to 105 St. Joseph St., Mobile, Ala.
E. K. Kerr, 1323 Washington Boul., to Cook County Hospital, Chicago.
G. E. Lyon, 188 S. Lincoln St., to 213 Winchester Ave., Chicago.
E. A. Lawbaugh, 237 LaSalle Ave., to Marshall Field Bldg., Chicago.
G. M. Luckey, 742 W. Adams St., to 806 Jackson Boul., Chicago.
J. K. Lewis, Argentine, Kan., to 1212 Troost Ave., Kansas City, Mo.
J. P. LaBarre, 317 Roland Ave., to 220 E. Montgomery St., Baltimore, Md.
G. McF. Mood, Summerville, Ill., to Summerville, S. C.
N. A. McCurdey, 735 Church St., to 371 Freemason St., Norfolk, Va.
B. MacMonagle, 610 Market St., to 590 Sutter St., San Francisco, Cal.
J. H. Metzger, 732 Jackson Boul., to 483 Ashland Boul., Chicago.
R. J. McDonald, 707 W. Harrison St., to 57 Flournoy St., Chicago.
H. M. Martin, 607 Van Buren St., to 274 Ashland Boul., Chicago.
A. A. Nichols, Atlanta, to Ivy Log, Ga.
V. V. Norton, Chicago, to Waverly, Iowa.
J. C. Paine, 124, to 2725 N. Adams St., Peoria, Ill.
C. Passudetti, Chicago, to Iron Mountain, Mich.
John Stout, Pender, to 1624 S. 10th St., Omaha, Neb.
J. C. Spencer, Crocker Bldg., to 590 Sutter St., San Francisco, Cal.
W. M. Shultz, 1871 Lafayette Ave., to 823 14th St., Denver, Colo.
O. L. Suggett, Jefferson Ave. and Olive St., to Commercial Bldg., St. Louis, Mo.
M. K. Scott, 1409 Troost Ave., to University Medical College, Kansas City, Mo.
G. E. Thompson, 72 Marietta, to 1 Chamberlin St., Atlanta Ga.

New Patents.

Patents of interest to physicians, Dec. 18 and 25:

664,351. Siphon-filler and mineral water charger. John H Fox, New York City.
664,318. Making soluble casein. Wm. A. Hall, Bellows Falls, Vt.
663,969. Massage chair. John M. Johnston and O. Vanorman, Los Angeles, Cal.
663,995. Germ-destroyer for telephone-mouthpieces. Lewis L. Lacey, Austin, Texas.
664,282. Vapor bath cabinet. George W. Merker, Belleville, Ill.
663,997. Atomizer, Roland Morrill, Benton Harbor, Mich.
663,978. Sanitary appliance. Arthur O'Brien, Helena, Mont.
664,308. Electrotherapeutic spectacles. Thomas B. Zeller, Pittsburg, Pa.
664,377. Guaiacolated serum and making same. Fernand Bellio [illegible]
[illegible] ration for medical use. Fernand Berlioz, Grenoble, France.
664,398. Abdominal support. Huldah S. Gates, Rosedale, Kan.
664,482. File for prescriptions. Harry I. Jeffers, Aberdeen, Miss.
664,495. Pessary. Horace M. Paine, Atlanta, Ga.
664,796. Rectal irrigator and insufflator. Rody E. Warner, Pittsburg, Pa.
664,516. Machine for manufacturing capsules for bottles or the like. Eduard Watzke, Friedberg, Austria-Hungary.

The Public Service.

Army Changes.

Movements of Army Medical Officers under orders from the Adjutant-General's Office, Washington, D. C., Dec. 27, 1900, to Jan. 2, 1901, inclusive:

George W. Adair, major and surgeon, U. S. A., member of retiring board convened in Chicago.

William B. Banister, major and surgeon, Vols. (captain and asst.-surgeon, U. S. A.), member of a board convened in Manila, P. I., for the examination of candidates for admission to the medical department of the army.

Alfred E. Bradley, captain and asst.-surgeon, U. S. A., member of a retiring board at St. Paul, Minn.

William H. Brooks, acting asst.-surgeon, from Fort Schuyler, N. Y., to San Francisco, Cal., for duty with troops en route to Manila, P. I., and subsequent assignment in the Division of the Philippines.

Marshall M. Cloud, lieutenant and asst.-surgeon, U. S. A., sick leave of absence extended.

Louis W. Crampton, major and surgeon, U. S. A., member of a board convened in Manila, P. I., to examine candidates for admission into the medical department of the army.

Calvin De Witt, lieutenant-colonel, deputy surgeon-general, U. S. A., member of a retiring board at St. Paul, Minn.

Thomas W. Jackson, acting asst.-surgeon, former orders amended so as to assign him to temporary duty at the general hospital, Presidio, San Francisco, Cal.

Theodore C. Lyster, lieutenant and asst.-surgeon, U. S. A., from duty in Cuba to Fort Schuyler, N. Y.

Walter Reed, major and surgeon, U. S. A., to represent the medical department of the army at the Pan-American Medical Congress, to meet in Havana, Cuba, Feb. 5, 1901.

William E. Richards, lieutenant and asst.-surgeon, U. S. A., leave of absence on account of sickness extended.

Major A. W. Shockley, lieutenant and asst.-surgeon, U. S. A., from duty in the Department of Cuba to Fort Niobrara, Neb.

Hobert E. Warren, acting asst.-surgeon, to duty as examiner of recruits at Denver, Colo.

Clark I. Wertenbaker, acting asst.-surgeon, from Fort Niobrara, Neb., to San Francisco, Cal., for duty with troops going to Manila, P. I., and subsequent assignment in the Division of the Philippines.

J. Samuel White, acting asst.-surgeon, former orders amended to direct him to report to the commanding general Department of California for duty at the general hospital, Presidio, of San Francisco, Cal.

In addition to the above orders, the following was issued Jan. 2, 1901: The following named acting asst.-surgeons, U. S. A., will proceed from the places hereinafter designated to San Francisco, Cal., and report in person to the commanding general, Department of California, for assignment to duty with troops en route to the Philippine Islands, where, upon arrival, they will report in person to the commanding general, Division of the Philippines, for assignment to duty:

John H. Allen, [illegible] C.; Henry D. Brown, from Denver, Colo.; [illegible] from Summerville, S. C.; Lawrence McEvoy [illegible]; Frederick H. Mills, from Buffalo, N. Y.; Joseph Pettyjohn, from Augusta, Ga.; Richard J. Price, from Wilmington, N. C.; Joseph W. Reddy, from Boston, Mass.; Shannon Richmond, from St. Joseph, Mo.; Anton R. Schier, from Burlington, Iowa; Alfred T. Short, from Montrose, Colo.; Robert S. Spilman, from Washington, D. C.; Theodore H. Weisenburg, from Philadelphia, Pa.

Navy Changes.

Changes in the Medical Corps of the Navy for the week ending Jan. 5, 1901:

Surgeon R. P. Crandall, detached from the U. S. T. S. *Constellation*, upon reporting of relief, ordered to temporary duty in connection with recruiting at Milwaukee, Wis., and then home to wait orders.

Surgeon W. A. McClurg, detached from the *Indiana*, and to naval training station, Newport, R. I., as the relief of Surgeon R. F. Crandall.

Asst.-Surgeon J. M. Brister, ordered to the *Independence*, Jan. 13, 1901.

Marine-Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the U. S. Marine-Hospital Service for the seven days ended Jan. 3, 1901:

Surgeon George Purviance, relieved from duty at Baltimore, Md., and directed to proceed to Washington, D. C., reporting at the bureau for duty.

P. A. Surgeon C. P. Wertenbaker, to proceed to Shreveport, La., for special temporary duty.

P. A. Surgeon W. G. Stimpson, to proceed to Denver, Colo., for special temporary duty.

P. A. Surgeon B. W. Brown, relieved from duty at Cape Charles quarantine and directed to proceed to Baltimore, Md., and assume command of the service, relieving Surgeon George Purviance.

Asst.-Surgeon C. W. Wille, to assume temporary command of Cape Charles quarantine, relieving P. A. Surgeon R. W. Brown.

Asst.-Surgeon J. W. Amesse, on being relieved by Asst.-Surgeon L. P. H. Bahrenburg, directed to proceed to Manila, P. I., and report to chief quarantine officer for duty.

Asst.-Surgeon B. J. Lloyd, granted leave of absence for 18 days from Dec. 11, 1900.

Asst.-Surgeon L. P. H. Bahrenburg, Bureau order of Dec. 27, 1900, directing Asst.-Surgeon Bahrenburg to proceed to Manila, revoked, and directed to proceed to Honolulu, H. I., reporting to the chief quarantine officer for duty.

Acting Asst.-Surgeon J. E. Bready, granted leave of absence for 4 days from Jan. 2, 1901.

Hospital Steward W. W. Kolb, granted leave of absence for 30 days from Jan. 29, 1901.

Hospital Steward E. T. Olsen, granted leave of absence for 5 days.

CASUALTY.

Acting Asst.-Surgeon A. R. Booth, died at Shreveport, La., Dec. 27, 1900.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, U. S. Marine-Hospital Service, during the week ended Jan. 4, 1901:

SMALLPOX—UNITED STATES.

District of Columbia: Washington, Dec. 15-22, 1 case.

Florida: Jacksonville, Dec. 15-22, 1 case.

Illinois: Cairo, Dec. 15-22, 3 cases; Chicago, Dec. 22-29, 2 cases.

Kansas: Wichita, Dec. 22-29, 2 cases, 1 death.

Nebraska: Decatur, April 1-Dec. 14, 416 cases, 4 deaths.

New Hampshire: Manchester, Dec. 22-29, 14 cases.

New York: New York, Dec. 22-29, 11 cases, 2 deaths.

Ohio: Ashtabula, Dec. 22-29, 5 cases; Cleveland, Dec. 22-29, 20 cases.

Rhode Island: Central Falls, Dec. 26, 1 case.

Tennessee: Memphis, Dec. 22-29, 2 cases; Nashville, Dec. 22-29, 1 case.

Texas: Galveston, Dec. 17, 6 cases; Houston, Dec. 22-29, 25 cases, 1 death.

Utah: Salt Lake City, Dec. 22-29, 52 cases.

West Virginia: Wheeling, Dec. 15-22, 3 cases.

Wisconsin: Green Bay, Dec. 23-30, 1 case.

SMALLPOX—FOREIGN.

Argentina: Buenos Ayres, Oct. 1-30, 22 cases, 14 deaths.

Austria: Prague, Dec. 1-8, 26 cases.

Egypt: Alexandria, Nov. 26-Dec. 10, 4 cases, 4 deaths.

England: London, Dec. 1-15, 2 cases.

France: Paris, Nov. 24-Dec. 1, 103 cases, 17 deaths; Dec. 1-8, 152 cases, 14 deaths.

Greece: Athens, Dec. 1-8, 1 case.

India: Bombay, Nov. 21-27, 1 death; Calcutta, Nov. 17-24, 8 deaths; Madras, Nov. 17-23, 1 death.

Italy: Licata, Dec. 8-15, 1 death.

Mexico: Vera Cruz, Dec. 15-22, 1 death.

Russia: Moscow, Nov. 24-Dec. 1, 3 cases, 1 death; Odessa, Dec. 1-8, 23 cases, 7 deaths; St. Petersburg, Dec. 1-8, 5 cases, 3 deaths; Warsaw, Dec. 1-8, 15 deaths.

Scotland: Glasgow, Dec. 15-21, 67 cases, 3 deaths.

YELLOW FEVER.

Cuba: Havana, Dec. 8-22, 6 deaths.

Mexico: Vera Cruz, Dec. 15-22, 1 death.

CHOLERA.

India: Bombay, Nov. 21-27, 2 deaths; Calcutta, Nov. 17-24, 35 deaths; Madras, Nov. 17-23, 1 death.

PLAGUE.

India: Bombay, Nov. 21-27, 58 deaths; Calcutta, Nov. 18-24, 4 deaths.

Japan: Osaka, Nov. 30-Dec. 4, 4 cases.

Madagascar: Tamatave, Oct. 29-Nov. 18, 1 case.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

61 Market Street : : Chicago, Ill.

Cable Address: "Medic, Chicago"

Subscription price: Five dollars per annum in advance

Postage in the United States and Canada, Mexico, Hawaii, Guam, Porto Rico, and the Philippines, free; foreign postage, $2.50. Subscriptions may commence at any time. Volumes begin with the first issue of January and of July.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

The qualifications for membership require that the applicant be a member, in good standing, of a state or local medical society entitled to send delegates to the annual meeting of the American Medical Association. A list of these societies will be sent on request. Applications must be accompanied with a certificate showing that the applicant is a member of a recognized society, and should be sent with the annual dues—five dollars—to the treasurer, Dr. Henry P. Newman, 100 Washington Street, Chicago. Members receive The Journal free. Subscribers to The Journal may become members of the Association without additional expense if they are members of medical societies recognized by the Association. Those desiring to have their names transferred from the subscription to the membership lists should send certificates as above, with a receipt for their subscription to The Journal, covering the current fiscal year.

FISCAL YEAR.

The fiscal year of the American Medical Association is from January 1 to December 31; and the annual dues paid by a new member cover only the fiscal year, no matter at what time of year the membership is obtained. Those who pay their dues and join the Association at the annual meeting in June, for instance, pay only for the fiscal year which ends with the December following, and the annual dues for the following fiscal year are payable the succeeding January, at which time the treasurer sends a statement to each member. Such members, however, are entitled to The Journal for the full year, even though the membership be not continued.

PAPERS READ AT THE ANNUAL MEETING.

"Every paper received by this Association and ordered to be published, and all plates or other means of illustration, shall be considered the exclusive property of the Association. . . The Board of Trustees shall have full discretionary power to omit from the published transactions, in part or in whole, any paper that may be referred to it by the Association or either of the Sections, unless specially instructed to the contrary by vote of the Association." (From Article V of the By-laws.)

NEWS.

Our readers are requested to send us items of news of a medical nature, also marked copies of local newspapers containing matters of interest to members of the medical profession. We shall be glad to know the name of the sender in every instance.

ORIGINAL PAPERS.

Articles are accepted for publication with the understanding that they are contributed solely to this journal.

COPYRIGHT.

Matter appearing in The Journal of the American Medical Association is covered by copyright, but as a general thing, no objection will be made to the reproduction of anything appearing in its columns if proper credit be given.

CONTRIBUTIONS TYPEWRITTEN.

It will be satisfactory to all concerned if authors will have their contributions typewritten before submitting them for publication. The expense is small to the author—the satisfaction is great to the editor and printer. We can not promise to return unused manuscript.

Half-tones, zinc etchings and other illustrations will be furnished by The Journal when photographs or drawings are supplied by the author.

ADVERTISEMENTS.

Advertising forms go to press eight days in advance of the date of issue. Therefore, in sending in copy, time should be allowed for setting up advertisements and for the sending and return of proofs. Advertising rates will be made known on request.

CHANGE OF ADDRESS.

In ordering a change of address it is important that both the old and new addresses be given.

REMITTANCES.

Remittances should be made by check, draft, registered letter, money or express order. Currency should not be sent, unless registered. Stamps in amounts under one dollar are acceptable. Make all checks, etc., payable to "Journal American Medical Association," except those for annual dues. These should be made payable and sent direct to the Treasurer, Dr. Henry P. Newman, 100 Washington Street, Chicago.

Original Articles.

THE DIAGNOSIS OF DIABETES MELLITUS.*

JAMES B. HERRICK, M.D.
CHICAGO.

The crucial test in the diagnosis of diabetes mellitus is the examination of the urine for sugar and the determination of the question as to whether the glycosuria is transitory or not. In practice, however, it is impossible to examine the urine of all patients. While the routine first examination of the urine of every new patient and the frequent examination of the urine of old patients will detect many cases of diabetes that might otherwise escape notice, one must of necessity be directed toward the uranalysis by certain symptoms that lead one to suspect the existence of this disease. The common symptoms are great thirst, weakness and emaciation in spite of an excessive appetite, subnormal temperature and polyuria. With these classical symptoms well-marked, the attention is quickly drawn to the probable nature of the malady and the sugar found. But in many cases these symptoms are not prominent or some other symptom is so pronounced as to attract the attention of both patient and physician in another direction. It is well, therefore, to be familiar with the rarer and more atypical manifestations of the disease, and particularly because many of these symptoms appear early and in the milder cases, which, if taken in time, may be materially improved by treatment. Many of these phenomena that I shall describe as symptoms are in reality complications, but I shall refer to them, rather loosely, perhaps, as symptoms, as something occurring because of the diabetes, indicating its possible existence and therefore of aid in diagnosis. To enumerate them all here would be undesirable and impossible within the limits of this paper. I shall restrict myself, therefore, to points that have seemed to me, from reading and practice, of the greatest value, striving to emphasize those most apt to be lightly passed over and passing lightly over those that are so clearly emphasized by the experience of every practical physician as to need but passing comment.

Nervous System.—Poor nutrition and toxemia will account for the many manifestations of disturbed function on the part of the nervous system. Neuralgias are common, especially sciatica, which is apt to be bilateral, a condition, however, that I have never seen in diabetes, though I have been on the look-out for it for twelve years. Polyneuritis is occasionally seen, especially in the diabetic who is also alcoholic. Neuralgia or neuritic pains in the legs with the loss of patellar reflex—a common event in diabetes—and an uncertain gait may readily lead to a diagnosis of true tabes; and this latter condition may occasionally be found with diabetes. Trophic disturbances, such as falling out of the nails, bullæ, herpes zoster and perforating ulcer, are sometimes seen. Peripheral motor paralysis, as in the abducens or the spinal accessory, has been seen. Cerebral palsies recalling the paralyses of uremia and of lead poisoning are sometimes met with, an aphasia, monoplegia or even a hemiplegia being present with no anatomical lesion found post-mortem. These are distinct from the hemiplegias due to cerebral hemorrhage from the sclerotic vessels so commonly met with in diabetes. Headache and dizziness, one or both, caused ten of Naunyn's patients to seek advice of a physician. Sleeplessness or drowsiness, even narcolepsy, are sometimes present.

The eye may give evidence of diabetes by errors of accommodation, paralysis of the external muscles, by retinitis, more rarely optic atrophy or by cataract. Rapidly developing double cataract in the young should arouse suspicion of diabetes.

Besides furuncles in the external ear, which is not at all uncommon, suppuration of the middle ear may occur, and several observers have called attention to the early and rapid involvement of the mastoid in these cases. Eulenstein[1] has recently reviewed the entire subject.

Two symptoms that seem to deserve special notice are impotence and psychic disturbances. In some cases undue sexual excitability may be present. In most, however, a distinct loss of sexual vigor is noted and is often a source of much worry. About six years ago a colored medical student asked me to see him for a cough and great weakness. The cough I found due to tuberculosis complicating diabetes. This, by the way, is the only case of diabetes in the colored I have seen. This latter condition he had been aware of for about a year, but was very bitter in his denunciation of many doctors in many towns whom he had consulted during the preceding five years for impotence, all of whom, as he said, took his money but did not examine his urine. Not until he came to Ann Arbor did a physician examine the urine and tell him his impotence was but a manifestation of diabetes. I have known other cases in which impotence induced the patient to seek aid of the physician. It is often a very early symptom.

The psychic disturbances of diabetes, while dwelt upon by French writers, are, it seems to me, slighted by many, and among others by no less an authority than Naunyn. In several instances I have seen marked psychic disturbances. An old lady imagined that at night people came into her room, conversed with her, brought her things to eat, etc., and the next day related as facts these imaginary events. A man of 60 became cross, irritable and unreasonable, where before he had

Cuba: Havana, Dec. 8-22, 6 deaths.
Mexico: Vera Cruz, Dec. 15-22, 1 death.

CHOLERA.

India: Bombay, Nov. 21-27, 2 deaths; Calcutta, Nov. 17-24, 35 deaths; Madras, Nov. 17-23, 1 death.

PLAGUE.

India: Bombay, Nov. 21-27, 58 deaths; Calcutta, Nov. 18-24, 4 deaths.
Japan: Osaka, Nov. 30-Dec. 4, 4 cases.
Madagascar: Tamatave, Oct. 29-Nov. 18, 1 case.

THE JOURNAL OF THE
AMERICAN MEDICAL ASSOCIATION

61 Market Street : : Chicago, Ill.

Cable Address: "Medic, Chicago"

Subscription price: Five dollars per annum in advance

Postage in the United States and Canada, Mexico, Hawaii, Guam, Porto Rico, and the Philippines, free; foreign postage, $2.50. Subscriptions may commence at any time. Volumes begin with the first issue of January and of July.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

The qualifications for membership require that the applicant be a member, in good standing, of a state or local medical society entitled to send delegates to the annual meeting of the American Medical Association. A list of these societies will be sent on request. Applications must be accompanied with a certificate showing that the applicant is a member of a recognized society, and should be sent with the annual dues—five dollars—to the treasurer, Dr. Henry P. Newman, 100 Washington Street, Chicago. Members receive The Journal free. Subscribers to The Journal may become members of the Association without additional expense if they are members of medical societies recognized by the Association. Those desiring to have their names transferred from the subscription to the membership lists should send certificates as above, with a receipt for their subscription to The Journal, covering the current fiscal year.

FISCAL YEAR.

The fiscal year of the American Medical Association is from January 1 to December 31: and the annual dues paid by a new member cover only the fiscal year, no matter at what time of year the membership is obtained. Those who pay their dues and join the Association at the annual meeting in June, for instance, pay only for the fiscal year which ends with the December following, and the annual dues for the following fiscal year are payable the succeeding January, at which time the treasurer sends a statement to each member. Such members, however, are entitled to The Journal for the full year, even though the membership be not continued.

PAPERS READ AT THE ANNUAL MEETING.

"Every paper received by this Association and ordered to be published, and all plates or other means of illustration, shall be considered the exclusive property of the Association. . . The Board of Trustees shall have full discretionary power to omit from the published transactions, in part or in whole, any paper that may be referred to it by the Association or either of the Sections, unless specially instructed to the contrary by vote of the Association." (From Article V of the By-laws.)

NEWS.

Our readers are requested to send us items of news of a medical nature, also marked copies of local newspapers containing matters of interest to members of the medical profession. We shall be glad to know the name of the sender in every instance.

ORIGINAL PAPERS.

Articles are accepted for publication with the understanding that they are contributed solely to this journal.

COPYRIGHT.

Matter appearing in The Journal of the American Medical Association is covered by copyright, but as a general thing, no objection will be made to the reproduction of anything appearing in its columns if proper credit be given.

CONTRIBUTIONS TYPEWRITTEN.

It will be satisfactory to all concerned if authors will have their contributions typewritten before submitting them for publication. The expense is small to the author—the satisfaction is great to the editor and printer. We can not promise to return unused manuscript.

Half-tones, zinc etchings and other illustrations will be furnished by The Journal when photographs or drawings are supplied by the author.

ADVERTISEMENTS.

Advertising forms go to press eight days in advance of the date of issue. Therefore, in sending in copy, time should be allowed for setting up advertisements and for the sending and return of proofs. Advertising rates will be made known on request.

CHANGE OF ADDRESS.

In ordering a change of address it is important that both the old and new addresses be given.

REMITTANCES.

Remittances should be made by check, draft, registered letter, money or express order. Currency should not be sent, unless registered. Stamps in amounts under one dollar are acceptable. Make all checks, etc., payable to "Journal American Medical Association," except those for annual dues. These should be made payable and sent direct to the Treasurer, Dr. Henry P. Newman, 100 Washington Street. Chicago.

THE DIAGNOSIS OF DIABETES MELLITUS.*

JAMES B. HERRICK, M.D.
CHICAGO.

The crucial test in the diagnosis of diabetes mellitus is the examination of the urine for sugar and the determination of the question as to whether the glycosuria is transitory or not. In practice, however, it is impossible to examine the urine of all patients. While the routine first examination of the urine of every new patient and the frequent examination of the urine of old patients will detect many cases of diabetes that might otherwise escape notice, one must of necessity be directed toward the uranalysis by certain symptoms that lead one to suspect the existence of this disease. The common symptoms are great thirst, weakness and emaciation in spite of an excessive appetite, subnormal temperature and polyuria. With these classical symptoms well-marked, the attention is quickly drawn to the probable nature of the malady and the sugar found. But in many cases these symptoms are not prominent or some other symptom is so pronounced as to attract the attention of both patient and physician in another direction. It is well, therefore, to be familiar with the rarer and more atypical manifestations of the disease, and particularly because many of these symptoms appear early and in the milder cases, which, if taken in time, may be materially improved by treatment. Many of these phenomena that I shall describe as symptoms are in reality complications, but I shall refer to them, rather loosely, perhaps, as symptoms, as something occurring because of the diabetes, indicating its possible existence and therefore of aid in diagnosis. To enumerate them all here would be undesirable and impossible within the limits of this paper. I shall restrict myself, therefore, to points that have seemed to me, from reading and practice. of the greatest value, striving to emphasize those most apt to be lightly passed over and passing lightly over those that are so clearly emphasized by the experience of every practical physician as to need but passing comment.

Nervous System.—Poor nutrition and toxemia will account for the many manifestations of disturbed function on the part of the nervous system. Neuralgias are common, especially sciatica, which is apt to be bilateral, a condition, however, that I have never seen in diabetes, though I have been on the look-out for it for twelve years. Polyneuritis is occasionally seen, especially in the diabetic who is also alcoholic. Neuralgia or neuritic pains in the legs with the loss of patellar reflex—a common event in diabetes—and an uncertain gait may readily lead to a diagnosis of true tabes; and this latter condition may occasionally be found with diabetes. Trophic disturbances, such as falling out of the nails, bullæ, herpes zoster and perforating ulcer, are sometimes seen. Peripheral motor paralysis, as in the abducens or the spinal accessory, has been seen. Cerebral palsies recalling the paralyses of uremia and of lead poisoning are sometimes met with, an aphasia, monoplegia or even a hemiplegia being present with no anatomical lesion found post-mortem. These are distinct from the hemiplegias due to cerebral hemorrhage from the sclerotic vessels so commonly met with in diabetes. Headache and dizziness, one or both, caused ten of Naunyn's patients to seek advice of a physician. Sleeplessness or drowsiness, even narcolepsy, are sometimes present.

The eye may give evidence of diabetes by errors of accommodation, paralysis of the external muscles, by retinitis, more rarely optic atrophy or by cataract. Rapidly developing double cataract in the young should arouse suspicion of diabetes.

Besides furuncles in the external ear, which is not at all uncommon, suppuration of the middle ear may occur, and several observers have called attention to the early and rapid involvement of the mastoid in these cases. Eulenstein[1] has recently reviewed the entire subject.

Two symptoms that seem to deserve special notice are impotence and psychic disturbances. In some cases undue sexual excitability may be present. In most, however, a distinct loss of sexual vigor is noted and is often a source of much worry. About six years ago a colored medical student asked me to see him for a cough and great weakness. The cough I found due to tuberculosis complicating diabetes. This, by the way, is the only case of diabetes in the colored I have seen. This latter condition he had been aware of for about a year, but was very bitter in his denunciation of many doctors in many towns whom he had consulted during the preceding five years for impotence, all of whom, as he said, took his money but did not examine his urine. Not until he came to Ann Arbor did a physician examine the urine and tell him his impotence was but a manifestation of diabetes. I have known other cases in which impotence induced the patient to seek aid of the physician. It is often a very early symptom.

The psychic disturbances of diabetes, while dwelt upon by French writers, are, it seems to me, slighted by many, and among others by no less an authority than Naunyn. In several instances I have seen marked psychic disturbances. An old lady imagined that at night people came into her room, conversed with her, brought her things to eat, etc., and the next day related as facts these imaginary events. A man of 60 became cross, irritable and unreasonable, where before he had been of a quiet, mild disposition. Diabetes was discovered just before he went into a fatal coma. A physician of 55 grew, as he expressed it, ill-natured and ugly of disposition; he scolded, burst out into fits of anger that would drive his wife weeping from the table; then in remorse he contemplated suicide. His wife told me she feared he would take her life or his own and she thought he must be insane. The diagnosis of diabetes once made and treatment instituted, his disposition changed back to its old character, and he became once more the jovial, good-natured man and the kind and indulgent father and husband. This case well illustrates the improvement in the mental condition that follows improvement in the underlying disease, a characteristic of the psychic disturbances in diabetes with the exception of the more chronic and more fully developed cases.[2]

* Presented to the Section on Practice of Medicine, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

[1] Deutsches Archiv f. Klin. Med., Bd, lxvi, p. 720.

Alimentary Tract.—Dry mouth, stomatitis, gingivitis, falling out of the teeth are so common as to need only mention. Dilatation of the stomach from overdistension with atony may be extreme. And it is surprising how with the enormous increase in size the stomach often seems functionally perfect, digesting food rapidly and with no apparent retardation of absorption or propulsion. I have seen the greater curvature nearly to the symphysis pubis and yet none of the subjective phenomena of an enlarged and functionally imperfect organ. Constipation is often extremely distressing, Vomiting and diarrhea when they occur and persist should be regarded as possible forerunners of coma, or at least of rapid loss of strength. The gastric juice shows no constant changes. An enlarged liver may be fatty or the cirrhotic liver sometimes seen, particularly with the bronzing of the skin—the diabetic bronze of the French.

The Skin.—The itchy skin should attract attention to the urine for the possible presence of sugar as much as for bile or albumin. The tendency to local suppuration of the skin, often of a sluggish character, is well known. Many a diagnosis of diabetes has been made because furuncles or carbuncles have caused the physician to suspect diabetes. Eczema, dermatitis, especially about the genitalia, and balanitis, should lead to a similar suspicion. The gangrene of the extremities is probably in all cases to be referred to the sclerotic condition of the vessels, as in the ordinary senile gangrene. Perforating ulcer of the foot with other trophic disturbances of the skin has already been referred to.

The Circulatory System.—Arteriosclerosis is a common finding in diabetes, at times to be regarded as a sequence of the prolonged toxemia, but often as a result of the gout, syphilis, old age or heredity, that may also be a causal antecedent of the diabetes. Absence of enlarged heart and thickened vessels does not, however, by any means exclude diabetes, for in some cases no cardiac changes are present and there may be even atrophy. To the arteriosclerosis are to be attributed many of the complications and accidents, such as gangrene, cerebral hemorrhage, myocarditis with perhaps acute dilatation or angina pectoris, and the sclerotic kidney.

The Blood.—From a diagnostic standpoint little is to be learned from the blood. Lipemia is not uncommon. There are no characteristic alterations in the red or white corpuscles. The color reactions of Bremer[3] and Williamson[4] are of confirmatory value and might enable one to recognize a diabetes even without glycosuria. Williamson has obtained his reaction from the blood of a known diabetic at a time when the urine was free from sugar.

The Urine.—There is little that is characteristic in the urine that is of great diagnostic value aside from its containing sugar. It is generally increased in amount, light in color, of a sweetish odor, of high specific gravity and acid in reaction. Albumin and casts may be present without other evidence of nephritis. Genuine nephritis may supervene, and under these circumstances the sugar may disappear. Many variations from the normal urine as regards its chemical composition are of pathological, perhaps of prognostic, interest, but can not be given much value when viewed from the standpoint of diagnosis. Variations in the amount of creatin, uric acid, oxalates, sulphates, and phosphates possess little clinical interest. The presence of aceton, diacetic acid, Beta-oxybutyric acid and the amount of ammonium excreted, are of greater value in prognosis and therapy than in diagnosis. The readiness of the saccharine urine to ferment is sometimes shown by the occurrence of this process in the bladder; cystitis may thus arise. Even pneumaturia has been noted.

The attention once directed to the urine, either as a part of the routine examination of a patient or because of some of the symptoms already enumerated, the diagnosis is generally readily made. Yet cases may be overlooked and it is well to consider the possible sources of this error. We may divide these errors into three groups and say that diabetes is not recognized because: 1. There is an error in the examination for sugar. 2. The urine is not examined for sugar. 3. There is no sugar in the urine at the time of examination.

1. Error in the technique of the examination will not be here considered.

2. The urine may not be examined for sugar.

The classical symptoms may not be present and the complications may not be recognized as possibly of diabetic origin. It is surprising how many of the milder cases of diabetes have little or no polyuria, emaciation or weakness and how readily a slight increase in the thirst and appetite may be overlooked. These are the individuals who, regarding themselves as in perfect health, apply for life insurance and who are surprised to learn from the examining physician that there is sugar in the urine. When such a patient consults a physician for a neuralgia, constipation, pruritus, balanitis, sexual weakness or because he feels a little run down in the spring and wishes a tonic, the trifling character of the complaint with the absence of marked classical symptoms of the disease may lead the physician rather carelessly to omit the uranalysis. And this is particularly liable to occur in the case of the family physician who has known his patient for years, has frequently examined him and prescribed for trifling ailments, and who may know that the urine on the occasion of previous examinations has been entirely normal.

The classical symptoms may be, or at least may have been, present but are so overshadowed in the minds both of the patient and physician by some serious complication that no thought of diabetes occurs. Pseudotabes or genuine tabes, cerebral hemorrhage, angina pectoris may so dominate the case as to cause one to overlook an underlying diabetes. And a dyspnea in a patient with thickened vessels and enlarged left heart, with somnolence deepening to coma may pass as uremia when there is an albuminous urine loaded with casts, a condition not at all uncommon in diabetic coma.

[3] Medical News, February, 1895, and elsewhere.

[4] British Medical Journal, Sept. 1896.

And I would here emphasize the fact that casts are very common in diabetic coma. This phenomenon, to which attention was first called by the late E. Külz, and which has been confirmed by Aldehoff,[5] Williamson and others, is worthy of note for two reasons. 1. It may give warning of the approach of coma, being occasionally seen even in the prodromal stage. Külz described such cases and Williamson has seen the same thing occur. I have seen casts in the urine in four cases of diabetic coma, in fact in all the cases of this form of coma I have seen since my attention was first called to Külz's phenomenon by reading Williamson's book.[6] In one case, that of a man about 60, the urine on standing showed a light yellowish or grayish sediment that consisted of an enormous number of the typical short, finely granular "coma-casts," as Aldehoff calls them. There were as many casts in a field as I have ever seen in any nephritic urine. There was but a trace of albumin. A few weeks ago the urine of a woman with diabetes revealed no casts in the centrifugalized specimen. Two days later coma began and casts were abundant. 2. A knowledge of the occurrence of casts in the urine of diabetic coma will enable the physician to avoid mistaking this form of coma for uremia, because of the albumin and casts.

On examining the urine it may be found of low specific gravity and on this account the examination for sugar may be deemed unnecessary. This is a grave error. The sugar-containing urine of diabetes may be of low specific gravity from a variety of causes. Strümpell says that it may be low when there is pronounced debility. The development of chronic interstitial nephritis will lower the specific gravity and might offer an explanation for the increased amount of urine and the thirst, as well as for other symptoms. In the latter part of April of this year I examined a man of 54, a diabetic, which diagnosis had been made two years before. He had a consolidated left apex. The total urine for twenty-four hours was 1500 c.c., it contained a moderate trace of albumin, casts, a small amount of sugar. Its specific gravity was but 1012. Another cause for low specific gravity is the drinking of large amounts of fluids. A patient of mine drinking large amounts of some spring water kept the specific gravity between 1015 and 1019, yet there was always sugar in the urine. Another patient after drinking beer all the morning passed urine with a specific gravity of 1004 and yet containing abundance of sugar. Cases with a specific gravity as low as 1002 are reported. And in the series of cases of Külz, many times records of 1010 or under were made. The importance, therefore, of examining for sugar even when the specific gravity is low is clearly seen, and the rules of some of our life insurance companies requiring such examination only when the specific gravity is above 1015 or 1020 need radical revision.

There may be no sugar in the urine at the time of examination.

At times a prediabetic or prodromal polyuria is seen without glycosuria; and as the sugar disappears in cases of permanent or temporary recovery there may be a non-saccharine polyuria.

When chronic interstitial nephritis occurs sugar may diminish, or even entirely disappar.

Acute infectious diseases, as pneumonia, influenza, typhoid fever, frequently cause a temporary disappearance of the sugar. These infectious diseases are often wrongly assigned as the cause of diabetes. For if a patient with pneumonia shows no sugar in the urine and a week after defervescence sugar appears and remains, one could readily reach the conclusion that the pneumonia was the exciting cause of the glycosuria, when in reality exactly the opposite is the fact; the sugar formerly present has disappeared under the influence of the acute infection only to reappear later.

The glycosuria in some of the milder forms of diabetes may be periodic or cyclic, reminding one of the cyclic albuminurias. An examination at a sugar-free period would therefore lead one to a false conclusion, unless subsequent control examinations were made, and especially examinations following a known diet of carbohydrates—similar to the test for alimentary glycosuria.

In conclusion, I would call attention to the importance not only of diagnosing the diabetes, but of recognizing the variety of the disease. While the classifications are all more or less artificial, they are yet valuable, and if we make no sharper distinction than between mild, moderately severe and severe types, our treatment will be far more rational and effectual and our prognosis far nearer the truth than if we make merely one large class including all cases of diabetes. Due consideration of the age, tendency to obesity, heredity and of organic disease of the pancreas or nervous system as an etiologic factor enables one to recognize the type. And of especial value is it to note the effect of withdrawal of carbohydrates. In many of the milder types, particularly in the obese adult, the sugar can be made quickly to disappear from the urine by proper diet, while in severer forms, in spite of most rigid diet, sugar persists. It is not always the amount of sugar that determines the severity of a given case; it is rather the amount in comparison with the amount of carbohydrates in the diet.

DIABETES MELLITUS.

THE MORTALITY THEREFROM IN THE CITY OF NEW YORK DURING THE PERIOD FROM 1889 TILL 1899; FROM THE OFFICIAL RECORDS. COMMENTS.*

HEINRICH STERN, PH.D., M.D.
NEW YORK CITY.

It is an exceptional occurrence that the mortality statistics of diabetes mellitus are closely studied. This has been especially the case with the pertinent statistic material of American communities. The principal cause for this omission lies undoubtedly in the supposed rare appearance of the affection. It is possible that diabetes in bygone years, before the strong current of immigration had set in, was of less frequency on this continent and that the proportion of deaths following this condition was smaller than it is to-day, but it is also possible that the American practitioner of some generations ago did not recognize the disease as readily as we modern Esculapians do.

The mortality statistics of the American metropolis in regard to diabetes mellitus, heretofore, were hardly ever thoroughly revised and studied. I am greatly indebted to Dr. Roger S. Tracy, one of the eminent statisticians of this country and the registrar of the New York Board of Health, for the assistance he so generously has lent me in the compilation of the statistic material and for the privilege of granting me access to the original documents. This communication treats only of a portion of the relevant matter—the elaboration of other statistics, especially those for the year 1899, I have reserved for another communication.[1]

[6] Herrick: Notes on Diabetes, Amer. Jour. Med. Science, July, 1900.

* Presented to the Section on Practice of Medicine, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

TOTAL MORTALITY FROM DIABETES MELLITUS.

Year.	Males.	Females.	Total number.
1889	71	47	118
1890	72	58	130
1891	64	66	130
1892	66	57	123
1893	76	61	137
1894	87	79	166
1895	95	108	203
1896	98	116	214
1897	95	107	202
1898	108	130	238
1899	104	102	206
Total in years	936	931	1867

Of 1867 deaths from diabetes mellitus, 931, that is, almost 50 per cent. occurred in females. This proportion differs widely from the supposition that the affection is much more fatal in males than in females. Former mortality reports have shown that from two to two and a half times more men succumbed to this malady than women. That in both sexes the death frequency from diabetes mellitus should be so equally proportioned may be partially attributed to the struggle for existence from which the modern woman is no longer exempt. Moreover, it is but consequential to assume that the death-rate from diabetes mellitus stands in direct proportion to the frequency of the disease itself, and that in New York City about equal numbers of both sexes are afflicted with it.

The following table gives the population of New York City—Manhattan and Bronx—estimated for July 1, in each year, total deaths, total death-rate per 1000 of the population, death-rate from diabetes mellitus per 1000 of population, and deaths from diabetes per 1000 deaths, from 1889 till 1899, inclusive.

Year.	Population	Total deaths.	*Total death-rate per 1000.*	*Death-rate from D. M. per 1000 population*	*Deaths from D. M. per 1000 deaths.*
1889	1,566,801	39,679	25.32	0.07	2,95
1890	1,612,559	40,103	24.87	0.08	3.25
1891	1,659,654	43,659	26.31	0.08	2.95
1892	1,708,124	44,329	25.95	0.07	2.8
1893	1,758,010	44,486	25.30	0.08	3.11
1894	1,809,353	41,175	22.76	0.09	4.05
1895	1,879,195	43,420	23.11	0.11	4.72
1896	1,934,077	41,622	21.62	0.11	5.09
1897	1,990,562	38,879	19.53	0.10	5.18
1898	2,048,830	40,438	19.73	0.11	5.95
1899	2,117,106	39,911	18.85	0.09	5.15

The death-rate from diabetes mellitus varied for the different years between 0.07 and 0.11 for each 1000 of the population. In the influenza year—1889 till 1890—the mortality from diabetes mellitus per 1000 of the population amounted to but 0.8—that is, the second lowest figure in the table. It is a remarkable fact that while the total death-rate has been in a rapid decline—25.32 per 1000 population in 1889, to 18.85 per 1000 population in 1899—the mortality-rate from diabetes mellitus per 1000 population has been on the increase since 1894.

The deaths from the affection per 1000 total deaths were from the minimum 2.8, in 1892, to the maximum 5.95, in 1898.

While the increase in the death-rate from diabetes mellitus per 1000 of the population during the past six years—1894 till 1899—inclusive, is plainly noticeable, the increase of deaths attributed to diabetes mellitus per 1000 total deaths is still more striking. From 1889 till 1893, inclusive, the average mortality from this disease per 1000 reported deaths amounted to 3.01; for the following six years, 1894 till 1899, inclusive, the proportion rose to 5.02, an increase of 66 per cent.

On the other hand, the increase of the death-rate from diabetes mellitus per 1000 of population, from 0.076, the average of the lustrum 1889-93 to 0.1, the mean of the past six years, amounts to but 25 per cent.

While the death-rate from diabetes mellitus per 1000 of the population for the period of 1894-99 is larger by 25 per cent. than that of the five preceding years, the deaths from diabetes mellitus per 1000 reported deaths had increased 66 per cent. for the same periods, or in other words, notwithstanding an absolute and relative increase, the latter in its proportion to 1000 inhabitants, *the greater frequency of the fatal termination of diabetes* compared with the total mortality is mainly due to the better and more general recognition of the disease. Formerly uranalysis was performed by but comparatively few physicians, and the true nature of the affection was not always recognized, and death, in many instances, was ascribed to other diseases than diabetes.

	160		158		164		164		147		140		136		155		141		190		134		178		

An examination of the foregoing table reveals the notable fact that the month in which the most deaths from diabetes occurred is October, while the one in which the mortality from this disease was lowest is the month just following, November. The total mortality from diabetes for the period of 11 years for each month fluctuates between the two extremes, 190 deaths in October and 134 in November. It is remarkable how little the figures for certain months deviate from each other. Fatal terminations of the affection were recorded: January, 160; February, 158; March, 164; April, 164; May, 147; June, 140; July, 136; August, 155; September, 141: November, 134. In October and December the mortality from diabetes was somewhat greater, 190 and 178, respectively.

Classing the months into seasons, the following figures are obtained:

---

[1] Meanwhile this article has appeared in the Medical Record, on Nov. 17, 1900, under the title: "The Mortality from Diabetes Mellitus in the City of New York (Manhattan and The Bronx), in 1899." Classified according to month, sex, and age; also an exposé as to nationality, duration of residence in the United States, occupation, direct causes of death and accompanying diseases.

Spring: March, April and May	475 deaths,	or about 25 per cent.
Summer: June, July and August	431 deaths,	or about 23 per cent.
Fall: September, October and November	465 deaths,	or about 25 per cent.
Winter: December, January and February	496 deaths,	or about 27 per cent.
Total	1867 deaths,	100 per cent.

It is a noteworthy occurrence how almost uniformly the 1867 deaths were distributed over the different seasons. For a period of 11 years the total spring and fall mortality differed from each other but 10 deaths. The divergency between spring and fall mortality on the one side and the summer mortality on the other is somewhat greater, amounting, respectively, to 44 and 34 deaths in 11 years. The greatest divergency is found between summer and winter mortality, namely, 65 deaths in the period in question, or between 3 and 4 per cent.

Considering this last feature evolved by the statistics, it seems rather dubious whether temperature, sunshine, moisture, etc., as assumed by many authors, play any rôle whatsoever in the fatal termination of diabetes.

It could be surmised that the somewhat greater October mortality might be called forth by climatic occurrences; the validity of this assumption, however, is very questionable, as in the following month, November, when the climate does not differ materially from that of the preceding month, the mortality from diabetes was the lowest. The larger figure for October, in my opinion, is solely due to the fact that New York City is more populated during October than during any other month of the year. The people have then just returned from their summer sojourn in the country or abroad, and the exodus to southern regions has not yet begun. Many diabetics who have left the city during the summer months are among those who return and the mortality is somewhat increased simply by their presence in greater numbers.

The somewhat lessened mortality from diabetes during summer may be explained in a similar manner; a large percentage of the diabetics have bidden farewell to the sweltering city.

The mortality was greater in the male sex in January, February, June, October and December. The numebr of females who succumbed to diabetes was larger than that of the males in March, April, May, July, August, September and November.

MORTALITY FROM DIABETES MELLITUS ACCORDING TO AGE.

Deaths.	Percentage.		Age.
4	0.21	occurred	0—1
1	6.05	"	1
2	0.10	"	2
2	0.10	"	3
4	0.21	"	4
11	0.57	"	5—9
17	0.89	"	10—14
38	2.00	"	15—19
43	2.26	"	20—24
133	6.98	"	25—34
161	8.45	"	35—44
400	21.00	"	45—54
513	26.95	"	55—64
414	21.74	"	65—74
113	6.03	"	75—84
11	0.57	"	85 and over

The greatest mortality from diabetes was found to be between 55 and 64 years of age. From the 65th to the 74th year the mortality declined about 20 per cent. and was about the same as between the 45th and 54th years. Apart from the deaths under 1 year of age the mortality of diabetes increased to the period between the 55th and 64th years, after which it slowly decreased to the 74th year. A decline of about 70 per cent. in deaths from diabetes is noticed between the 75th and 84th years of age.

An abrupt rise of mortality is noted after the end of the 44th year. While but 161 deaths were recorded for the period between the 35th and 44th years, an even 400 occurred between 45 and 54 years of age. Over 70 per cent. of all deaths took place between the 45th and 74th years of age. The fact that but 11 instances are recorded where the patient has lived to the 85th year and above, tends to show that only a very small percentage of diabetics reach an exceptionally high age.

Moreover it must not be construed as if the individual who succumbed to diabetes in an advanced age was necessarily afflicted with the disease for a long period. It appears, on the contrary that the diabetic condition may be established late in life and that diabetes then acquired runs as rapid a course as in the very young.

From the 20th to the 24th year the mortality from diabetes in the male sex is almost three times as large as in the female. Between the 25th and the 34th year the male mortalty was found to be about 30 per cent. larger. From the 35th to the 44th year the mortality of the male exceeded by about 18 per cent. that of the female. In the period between 45 and 54 years, the mortality of both sexes was almost analogous, and in that between the 55th and 64th year the female mortality surpassed by a fair margin that of the male sex. In the next period, from the 65th to the 74th year, the female mortality was also greater than that of the male, and in the period following, from the 75th to the 84th year, the female mortality was almost twice that of the male. In the period above 85 years the male mortality exceeded 4.5 times that of the other sex.

Exposure, excesses of a different nature, mental and bodily strain and worry undoubtedly stand in a causative relationship to the more frequent occurrence of diabetes and the subsequent greater mortality of the male from this affection between the 20th and 44th years of life. From the 45th to the 74th year the external conditions of life of both sexes are more alike and we notice a relative decrease in the mortality of the male, although the absolute figures are highest during this period.

The cessation of the catamenia, which takes place in many instances after the 44th year has been passed, and in the wake of which occurrence grave systemic disturbances not infrequently make their appearance, undoubtedly helps to swell the female mortality from diabetes between the 45th and 48th year.

The very high mortality of females after the 55th year and before the 84th year is reached, does not seem to be caused by any especial factor or factors, but seems rather due to the better care a woman can very often bestow upon herself.

If we add together the figures from the 20th to the 84th year we find that for this period of life 884 deaths of males and 893 deaths of females from diabetes had ensued. These total figures are almost alike.

MORTALITY FROM DIABETES MELLITUS IN INFANCY AND EARLY ADOLESCENCE, 1889-99.

Judging by the mortality from diabetes mellitus in childhood, the period when this disease almost always terminates fatally, we may adduce that this malady is a rare affection in infancy and early adolescence. I found 4 cases of death from diabetes mellitus in infants below 1 year of age, during the 11 years from 1889-99; at 1 year of age, 1 death; at 2 years, 2 deaths; at 3 years, 2 deaths; at 4 years, 4 deaths ensued, that is 13 instances in which the disease terminated fatally below the 5th year of life. Between the 5th and 9th year 11 cases of death are on record for the period in question; from the 10th to the 14th year of life, I came across 17 recorded instances; and from the 15th to the close of the 19th year, the mortality from this affection amounted to 38. The total mortality from diabetes in infancy and early adolescence, being 79, forms about 4.25 per cent. of the total deaths from this disease during this period of 11 years. Of these 79 cases, 55, which is over 70 per cent., occurred between the ages of 10 and 19. The period of puberty seems to be without potent influence upon the production of diabetes mellitus or upon its fatal termination.

Of the 13 instances of death following the affection which occurred under 5 years of age, but 3 took place in females. Among the 66 other instances of deaths from diabetes in early life 33 ensued in males and 33 in females, exactly 50 per cent. in each sex. The external conditions of life in the United States as a general rule are in the mean the same for both sexes to the 20th year; a fact to which the equal distribution of the disease in both sexes may be well ascribed.

MORTALITY FROM DIABETES MELLITUS AMONG THE COLORED POPULATION OF NEW YORK CITY, 1889-99.

In the official records I find but 15 deaths from diabetes which as designated occurred among the colored population of New York City for the past 11 years.

I could not obtain exact figures of the colored population of each year comprised in the period in question, but it seems that the death-rate from this disease in the colored race, compared with that of the white population, is exceedingly low. This may be due, to either the infrequency in which the pathologic condition appears in the Ethiopian race, or to its occasional non-recognition when it is present. The great majority of the colored people belong to the lower strata of the populace, to that class which get along with a home-made diagnosis of its ailment or frequent dispensaries or "cheap" doctors. Thus it might happen, that the real disease is not infrequently overlooked and that the patient treats himself or is treated for another affection.

Of the 15 specified instances, 9 deaths occurred in males and 6 in females—a proportion divergent widely from that occurring in the white population.

56 East Seventy-sixth Street.

CUTANEOUS DISEASES ACCOMPANYING DIABETES.*

M. B. HARTZELL, M.D.
Instructor in Dermatology, University of Pennsylvania; Dermatologist to Methodist Hospital.
PHILADELPHIA.

In this paper I shall consider those cutaneous diseases which occur with more or less frequency in diabetes, many of which are extremely annoying and painful, others dangerous, contributing in no small measure to the fatal issue of the disease. The recognition of the causal relationship existing between these eruptions and the glycosuria is an absolute prerequisite to the successful treatment of the former; and, as in many instances they are the first noticeable symptoms of diabetes, they also possess distinct value in the diagnosis of this affection. The greater number of them are of an inflammatory character, resembling in a general way the inflammatory diseases of the skin due to other causes, but also presenting certain peculiarities as to location and course, which suggest their etiology. A few are so constantly associated with sugar in the urine that they deserve the name "diabétides," first proposed by Fournier to indicate cutaneous diseases peculiar to those suffering from diabetes.

When the glycosuria is accompanied by excretion of large quantities of urine and likewise in the late stages of the malady, the skin is apt to be extremely dry, owing to the great diminution in the quantity of perspiration and sebum excreted, and a constant desquamation of fine white scales goes on; the hair too, becomes thin, dry and lusterless. This abnormal dryness of the skin is usually accompanied by a more or less marked general pruritus. The nails of the fingers and toes are likewise apt to present various abnormalities. They are unusually brittle and devoid of their normal luster; and in exceptional cases some or all of them are lost. This fall of the nails may be preceded by evident disease, or it may occur without precedent alteration of the nail-structure. Hemorrhage may take place into the nail-substance and trophic changes leading to deformity may occur as the secondary consequences of a diabetic neuritis. Intense pruritus localized about the vulva in women, the scrotum in men, the perineum, anus, and inner surface of the thighs in both sexes, is an extremely common symptom of diabetes; indeed so frequent is this form of pruritus that its presence should invariably lead to an examination of the urine for sugar. The itching in this form of pruritus is almost unbearable, and the violent scratching and rubbing to which the patient is irresistibly impelled leads in most cases to the development of an eczema.

Various forms of erythema may occur; the commonest are symmetrical patches situated on the face and a papular variety met with usually in young subjects, consisting of split-pea-sized, pinkish, slightly elevated lesions, situated on the forearms and legs; these papules may coalesce after a time to form variously sized patches.

Urticaria of a chronic type is likewise met with in a certain proportion of cases, due either to the direct irritation of the skin by the sugar present in the circulation, or resulting from disturbances in the alimentary canal.

One of the commonest and most distressing cutaneous complications of diabetes is eczema, situated most frequently about the genitalia, especially in women. This may begin as a severe pruritus, no evidences of inflammation being at first visible, but presently the skin becomes inflamed, partly from the violent scratching to which the parts are subjected, partly from the irritation produced by various micro-organisms—torula cerevisiæ, etc.—whose growth is favored by the saccharine urine with which the parts are apt to be frequently soiled. In many instances the affection is eczematous from the beginning; the skin is a bright-red, and oozes a sticky serum which soon dries into thick crusts. The inflammation may be limited to the genitalia, but more commonly it spreads up over the abdomen and down over the thighs, oftentimes involving a considerable area. In many cases this eczema presents nothing peculiar except its localization; but it may assume a very acute erythematous form which runs a rapid course, a form regarded by some authors as characteristic of diabetes. In men the prepuce is often the seat of an eczematous inflammation of a very severe grade, which produces marked thickening and narrowing of the preputial orifice, with the formation of exceedingly painful fissures about its margin, leading in some cases to an extreme degree of phimosis. Balano-posthitis usually accompanies this condition of the prepuce, due to the retention of small quantities of saccharine urine after each act of micturition and the decomposition of the sebaceous material so abundantly excreted in this region. It is worth while bearing in mind that pruritus or eczema about the genitalia may be the first symptom of diabetes, occurring in patients who suffer neither from excessive thirst nor polyuria.

---

* Presented to the Section on Practice of Medicine, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

In elderly subjects and in the later stages of diabetes a severe form of acne—acne cachecticorum—may occur, due largely, no doubt, to the extreme malnutrition of the skin. In the same class of patients painful furuncles, occurring singly or, what is more common, in crops, and carbuncles, are common events; it is estimated that about one-third of all such affections are due to glycosuria. Carbuncle, besides being an extremely painful and exhausting affection, is often of very grave import, being in many cases the direct cause of the patient's death. The frequency of such local affections is probably due to the unusually favorable conditions offered by the sugar-saturated tissue for the growth of pyogenic micro-organisms. In their clinical features these furuncles and carbuncles do not differ from similar lesions occurring in the non-diabetic; therefore their occurrence should always suggest the possibility of their glycosuric origin, and lead to an examination of the urine.

As papillomatosis diabetica, Kaposi has described an unusual affection characterized by the sudden appearance of an inflammatory patch on the back of the hand which suppurated and was followed by ulceration. At the site of this ulcerating lesion numerous papillary outgrowths, partly red and oozing, and partly horny, were formed. The patient had suffered from saccharine diabetes for twenty years.

A much more serious complication than any of those already mentioned, is gangrene of the skin. This may exist as moist or dry gangrene, usually in single, but sometimes in multiple, lesions; it may be limited to the skin and subcutaneous tissues or it may involve the deeper structures, even affecting an entire extremity. In rare cases it occurs symmetrically on the extremities, and is then suggestive of Raynaud's disease; but the absence of the peculiar train of symptoms which precedes by some considerable time the death of the skin in this affection—local ischemia and asphyxia—will usually suffice to exclude it. Under the name of bullous serpiginous gangrene, Kaposi has described a rare form of diabetic dermatosis in which the death of the skin is preceded by a bullous eruption, the subsequent gangrene extending serpiginously. In diabetics gangrene of the skin may follow the most insignificant injury, or it may be the result of some one of the many inflammatory affections so common in this malady. It may even occur without any precedent injury or inflammation, and is then probably the result of a neuritis or changes in the vessels supplying the part.

One of the most characteristic eruptions of diabetes is that known under the name of xanthoma diabeticorum. Although it is said to occur in rare instances without glycosuria, yet sugar is found in the urine in so large a proportion of the cases that it may be regarded as almost pathognomonic of diabetes mellitus. The eruption is usually moderate in extent, affects by choice the elbows, knees, and buttocks, and consists of yellowish or yellowish-red, rather flat papules. A moderate degree of itching and stinging usually accompanies it. It appears somewhat abruptly, and lasts for a period varying from a few weeks to several months, or even years.

Certain other diseases of the skin may be mentioned which are occasionally associated with glycosuria, but in which the causal relationship of the latter has not yet been satisfactorily established.

Nagelschmidt has found glycosuria so often in psoriatic patients that he is of the opinion that some causal connection exists between psoriasis and diabetes; but this seems doubtful in view of the fact that in the vast majority of cases of the former affection no sugar is present in the urine. Glycosuria has also been found in a certain number of cases of dermatitis herpetiformis, but whether this is the cause or effect, or whether the association was only accidental, yet remains to be determined. In rare instances abnormal deposits of pigment take place in the skin, as in so-called bronze diabetes.

Purpura is also an occasional complication, occurring usually in the early stages, but it may also appear in the later stages of the malady, when it is probably the result of the dyscrasia often existing at this time. This complication, when of the hemorrhagic variety, may be the immediate cause of death.

A few words as to the treatment of these various affections of the skin must suffice. The local treatment is largely that of similar diseases occurring in the non-diabetic. In the inflammations so common about the genitalia scrupulous cleanliness will go far toward a cure, or if not a cure, relief. Indeed if the parts are frequently bathed before inflammatory symptoms have actually appeared, they may be entirely prevented, since, as has already been said, they are in large part due to the direct irritant effects of the saccharine urine on the skin. But the treatment of the underlying cause, the diabetes, is of far more importance than any local remedies. In many cases of genital eczema or pruritus which have obstinately resisted all local treatment, the distressing symptoms will rapidly disappear when the patient's diet is regulated so as to exclude sugars and starches.

DISCUSSION ON PAPERS OF DRS. HERRICK, STERN AND HARTZELL.

DR. S. SOLIS-COHEN, Philadelphia—The only way to avoid missing cases of glycosuria is to examine, as a routine measure, the urine of every patient, no matter how trivial his complaint appears to be. I have often found sugar in urine of low specific gravity. Every case of glycosuria, however, is no more diabetes than every case of albuminuria is Bright's disease, or nephritis. The time is coming when we shall recognize the varieties of morbid constitution of the urine as symptoms of various pathological conditions due to various etiological factors. It is true that the vast majority of cases of glycosuria are due to diabetes, yet there are many other conditions in which I do not refer merely to alimentary glycosuria, but to pathologic glycosuria apart from diet. We may find it in influenza, in malaria, and in convalescence from these affections. It is not uncommon in Graves' disease or in acromegaly. It may be intermittent or recurrent. I have seen a few cases confirming the opinions of text-books that bilateral sciatica may be due to diabetes. In every such case the urine should be examined before this condition is excluded.

DR. JAMES J. WALSH, New York City—I should like to call attention to the fact that certain diseases that were formerly considered to be rare are in reality frequent. One man in Washington has seen over one hundred cases of pernicious anemia. Dr. Stern has referred to the increase of diabetes, showing that the disease is now recognized oftener than it was. It is interesting to note that many patients die of tuberculosis, or of nephritis, without suspecting the presence of any diabetes. It is a well-known fact that about one-half of all cases that die of diabetes have some tuberculosis of the lungs at the time of their deaths. Practically all cases of diabetes have a certain amount of albumin and casts in the urine.

DR. JOHN J. MORRISSEY, New York City—In the consideration of diabetes there is one factor in the treatment of great prominence, that is, we should treat the diabetic and not the diabetes. Diabetes is produced by many causes. In examining the connection between tuberculosis and diabetes during the past year I found, among 100 cases examined, that glycosuria was present in 30 per cent. at least. Since then I have examined 50 other cases and found it present in 10 per cent. of the cases. Where we find skin diseases of a chronic character we should, as ordinary routine practice, examine the urine, particularly when we meet with furuncles or carbuncles. The medical treatment of the latter will prove slow and unsatisfactory when depending upon a diabetic causation unless the disease be treated. I do not believe that alimentary glycosuria ever develops into true diabetes; one is merely a symptom of dietetic disturbance, the other a disease of grave importance. Each case must be individualized. No restricted diet will be found adapted for all cases. The prognosis, when the disease is due to a dietetic factor, is good. In cases which have their origin in cerebral disease, and also in the involvement of the pancreas, the prognosis is always very grave. When impotency is found associated with diabetes, it may be that both arise from the same cause, and not as a sequence.

So far as the treatment of diabetes is concerned, it is in a very chaotic condition. After using strontium and the other preparations provided by the genial manufacturer, I find that it is best to rely upon opium or one of its various preparations.

DR. C. F. WAHRER, Ft. Madison, Iowa—It is easier to make a diagnosis of diabetes now than it was formerly. Indeed, a physician possessed of an average degree of intelligence can diagnose from 80 to 90 per cent. of all cases of diabetes. In speaking of the diagnosis it reminds me of a German friend who said: "I would rather make a diagnosis and have the patient die than to have the man survive and be unable to make a diagnosis." Of course, this is what interests the physician; but it does not interest the patient. I stand up here to make a plea for the patient. In dieting these patients by any rule of thumb that rigidly forbids all sugars and starches, and feeds them on meats and certain vegetables alone, on gluten biscuit, saccharin, glycerin, and a lot of other stuff that would ruin the digestion of a sound man, we do ourselves great injustice, and the patient a great wrong, even though we limit the excretion of sugar by this diet list. We by no means modify the real disease process; we but change the symptoms, we lessen the excretion of sugar—a mere symptom—and we increase the discomfort and misery of our patients. Just picture them for five to ten years existing on a diet that no well man could live on, to say nothing of the morbid cravings of one so sick as a diabetic. The rank and file of diabetics, especially the young, die despite all treatment and dieting. The differential of the sugar eliminated by the urine will not make up for any loss in the molecular changes going on in the nervous system. Let us first know our pathology before we follow rigid rules of treatment and dieting.

DR. A. E. ROUSSEL, Philadelphia—I think all agree that the diagnosis of diabetes presents no difficulty. We occasionally meet with a case which has been diagnosed as such that afterward proves to be merely a symptomatic exhibition of sugar in the urine. At the last meeting of the ASSOCIATION in Philadelphia, I reported the case of a patient who had been treated for nearly six years. The conditions presented by the patient after being placed in the hospital led us to believe it to be an undeveloped case of myxedema. Photographs were exhibited showing the results of the thyroid treatment: the patient resumed apparently the normal condition and the sugar entirely disappeared and continued in abeyance as long as the thyroid treatment was kept up. The treatment was discontinued for one year with a return of the myxedematous symptoms and the exhibition of large quantities of sugar in the urine. This goes to show that it is possible for cases of myxedema to have sugar in the urine, as has been recorded by several observers.

In regard to the question of diet I disagree with the last speaker regarding the fixed and fast rules in the average diet for the patient. No fixed and fast rules can be laid down for diet. The exhibition of diacetic acid, or oxybutyric acid, or of a large amount of acetone should be regarded as a danger signal of the approach of diabetic coma, and no matter what form of diet is in use it should be immediately changed for some other. Consequently the recognition of the above in the examination of the urine is to my mind more important than even the percentage of sugar present.

DR. O. T. OSBURNE, New Haven, Conn.—I think we should endeavor to get at this disease from an etiological standpoint. We know that 50 per cent. of the cases of diabetes show pancreatic disease; the other 50 per cent. may not show such a condition. We know that certain nervous diseases may produce diabetes; we know that myxedema and also exophthalmic goiter may produce diabetes. Again, as Dr. Stern has shown from the statistics given, at the time of the menopause, the woman seems to have diabetes. Sugar may appear in the urine in acromegaly and in thyroid disease, etc. These cases are interesting in that they show that we may get at the source of the trouble later. It also emphasizes the fact that it is objectionable to treat true diabetics with a strict dietetic course. It is certainly true that if we take away the carbohydrates we should substitute fats.

DR. JAMES B. HERRICK, Chicago—I was interested in the statements made by Dr. Stern in reference to the infrequency of diabetes in the colored race; it bears out the experience of physicians who have practiced among the black people. Possibly it may have something to do with their manner of living. I believe that it is Von Noorden who quotes the statement that among the upper 10,000 in Berlin there were more cases of diabetes than among the lower 100,000. I am sure that those who are in hospital work, and in private practice have been struck with the greater frequency with which we meet these cases in private practice than in hospitals. Diabetes is one of the rarest diseases to be met with in the public hospitals; yet in private practice the percentage of cases of diabetes met with is rather high. So it would seem that the manner of living has much to do with it; it is much more frequent among the higher than the lower classes.

Of course, I agree with Dr. Cohen that every case of glycosuria is not diabetes; I referred to that in my paper. Certainly there is a transient glycosuria that may occur from a variety of causes. There is an alimentary glycosuria and none will insist that it is a true diabetes. But we should here utter a word of caution in regard to going too far in that direction. While we believe that there is such a thing as a functional or non-organic albuminuria, still we know what great danger there is to our patients if we do not regard all these cases with suspicion; they may be forerunners or the beginnings of organic disease of the kidneys. And in a similar way we should be cautious in declaring that a given case is one of functional glycosuria. We should be on the look-out for genuine diabetes. In many of the milder forms of diabetes there may be a temporary disappearance of the glycosuria.

Dr. Cohen has referred to bilateral sciatica. In a part of my paper that I did not read I made mention of this complication. I have always looked out for bilateral sciatica in every instance of diabetes, but I have never yet seen a single case, although I know it is referred to by many writers. Dr. Walsh very properly calls attention to the importance of testing for sugar in the urine in cases of tuberculosis.

In regard to treatment, although not touched upon by the essayists, I wish to array myself on the side of the gentleman from Iowa, as against the indiscriminate and too vigorous enforcement of diet. We should take a more liberal view of the diet question, and this is in accord with the best writers upon, and the best observers of, diabetes. If we cut our patients off absolutely from carbohydrates there is great danger of coma supervening, which may come on rapidly. I also agree with the statement that we should not treat the diabetes, but the patient himself.

DR. HEINRICH STERN, New York City—In response to Dr. Herrick's statement that diabetes, as is the general opinion, is a disease of the well-to-do, I would like to state, that in my researches of the original death certificates in the city of New York, almost 70 per cent. of deaths occurred in tenement houses, a tenement house being a dwelling structure occupied by more than two families: 15 per cent. occurred in hospital practice and coroner's cases, and only about 15 per cent. in private houses. This tends to show that the malady, if it may be called such, has virtually little to do with high living. At the same time, my statistics show that the Jews have not diabetes as frequently as supposed, and that the Irish, on the other hand, seem to be those who have a larger mortality from diabetes mellitus. Possibly a Jew will take better care of himself, but it seems highly probable that alcohol is a very potent factor, indeed, in the production of diabetes.

Diabetes mellitus, as I have pointed out long ago, is not a disease per se, but merely a syndrome, merely a stage in the diabetic deterioration. I have recognized, in some instances even 2 or 3 years before the appearance of dextrose in the urine, that diabetes will occur. I divide the diabetic deterioration into three stages; 1, the preglycosuric stage; 2, the glycosuric stage, the diabetes mellitus of to-day; 3, the post-glycosuric stage, the toxemia, when aceton, aceton-acetic acid and levorotatory oxybutyric acid are present, and when the output of sugar has markedly diminished or entirely ceased.

Diabetes mellitus, or the diabetic deterioration, is a plasmolysis, and as such is not difficult to diagnose. It has nothing at all to do with glycosuria, glycosuria being merely a symptom of it, just as it is a symptom accompanying a great number of operations. I have seen glycosuria following simple chloroform anesthesia; I have seen it in the wake of the extirpation of tonsils and of the kidney: I have seen it occur after overeating, after indigestion and after headache.

The identification of dextrose is not an easy matter. It is for the chemist, not for the general practitioner of medicine. The copper tests should be abandoned altogether—Haynes', Elliott's, Fehling's, Trommer's Salkowski's—they all serve a purpose, but do a great deal of harm in the hands of the family *physician.*

Now, as the diabetic deterioration is a plasmolysis, how do we recognize it. I have showed some years since, that albumin may be split up *into a sugar molecule* on the one hand, and carbamid, or as it is wrongly called "urea," on the other. Carbamid plus glucose, or dextrose or whatever sugar of the series $C_6H_{12}O_6$ it may be, makes up albumin. In other words, I recognize the diabetic deterioration by the continued large output of carbamid + glucose; or in other words, if the egested nitrogen exceeds for any length of time the ingested nitrogen, and if at the same time sugar is excreted by the urine, then, and only then can we speak of a diabetic deterioration; then, and only then, diabetes mellitus, of the authors of to-day, is present.

I hesitate not for a *moment to state* that levorotatory oxybutyric acid and the fatal coma diabeticum are often the result of a too long continued rigid fat-*meat* diet. Coma associated with diabetes, however, is not necessarily diabetic coma. In all instances where an accompanying or intercurrent disease, like many of the chemical affections, as phthisis pneumonia, end in coma, and when diabetes is present we can not speak of a coma diabeticum. Coma following nephritic conditions, which are associated with glycosuria or diabetes, is by no means a true diabetic coma. This is only present when diabetes is unaccompanied by other *chronic* diseases, and when the coma shows the characteristic dyspneic *feature.* This dyspneic phenomenon, or Kussmaul's breathing, is the only characteristic symptom of true coma diabeticum. Without it, we have no right to term a coma, a diabetic coma; a coma accompanying diabetes is not necessarily a diabetic coma.

Injuries After Intubation.—A writer in the *Corr. f. Schw. Aerzte,* found more or less serious lesions of the mucous membrane in 11 out of 96 intubated patients. The subglottic portion of the larynx and the mucosa of the anterior wall of the trachea were most frequently the site of the lesion. The tubes used are usually too large, he thinks. When it is difficult to introduce the tube, the obstruction *is usually* edema and not spasm of the glottis.

POST-ANESTHETIC PARALYSES.[*]

C. C. HERSMAN, M.D.

Lecturer on Mental and Nervous Diseases, Western University of Pennsylvania, Medical Department: Physician to St. Francis Hospital for the Insane; Alienist to South Side Hospital: Member Allegheny County, West Virginia State, Pennsylvania State, and American Medical Association, etc.

PITTSBURG, PA.

Paralyses following an anesthetic which are due to that agent alone are more imagined than real. Were it not for those unfamiliar with the recent literature on the subject it would seem an imposition to burden the profession to enter further into the discussion. "Anesthesia paralysis," post-operative paralysis," etc., still in use, foster erroneous conclusions and should be dispensed with.

It is well known to neurologists that in many alcoholics, or other drug habitués, the vulnerability of a nerve trunk is so increased that a very moderate degree of pressure over it will produce a tingling or numbness, and slight injuries may even invite a neuritis.

However, we could not seriously consider an acute toxemia as an etiological factor diminishing the resistance of peripheral nerves, rendering them more susceptible to a peripheral palsy as a sequence of general anesthesia.

Seldom have I seen a post-anesthetic paralysis that did not clear up rapidly. Usually the paralysis is due to a lesion of the nerve trunk, the so-called peripheral or pressure type. In looking up the literature I find that there is little credence given to the anesthetic as the real cause.

Mally and Leszynsky, who have given as much light on the subject as any others, classify them as central, hysterical, reflex and peripheral. These paralyses are preventable in every case, and the serious attention of the surgeon should be directed toward suitable precautions as to position, etc., during anesthesia.

The central paralyses are, as a rule, immediate and are due usually to apoplexy. Since a very large number of persons who go under an operation are, by reason of age and vascular atheroma, predisposed to a stroke even from the most trifling causes, it is not unreasonable to suppose that such an accident would be a common occurrence. It is a fact, however, that apoplexy during anesthesia is so rare that it may be considered purely accidental and in no way connected with the anesthetic.

A hysterical paralysis is just as likely to be produced by other agents than anesthesia; in fact it is so rarely post-anesthetic that it may be considered accidental and due to the moral shock rather than to the anesthetic.

Reflex palsies are so extremely rare that those best competent to judge look upon them as purely accidental.

This brings us up to the peripheral palsy, which is the only one of importance to the anesthetist. That oftenest seen is paralysis of the brachial plexus, caused by elevation of the arms. This elevation—Trendelenburg position—puts the roots of the plexus, especially the upper roots, at a sharp angle with the transverse vertebral processes, the indirect pressure causing the paralysis. The upper roots suffer oftenest, as the angle is more acute than that of the lower. The most frequently involved is the deltoid muscle, although other muscles, infra-spinatus and supra-spinatus, have been paralyzed; also the radial, tibial and others, no doubt from a faulty position, such as an arm or leg hanging over the sharp edge of a table.

---

[*] Presented to the Section on Nervous and Mental Diseases, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

It appears then that the only type avoidable is the last mentioned. All faulty positions should be guarded against and no long-continued pressure of any nature should be allowed. This paralysis corresponds to the pressure type with a favorable prognosis. Recovery is the rule where there is no degeneration or atrophy. A severe numbness or even a slight paralysis is not uncommon from pressure on a nerve trunk in alcoholics, but the writer has never seen a case that did not fully recover.

If there is no degenerative atrophy the use of electricity is indicated. Massage, passive motion, and injections of strychnia in the region of the nerve trunk, have done good.

As precautionary measures the surgeon should not permit too long an elevation of the arms, tight clamps or straps, head resting on the arm or an extremity hanging over the table. The fallacy among medical men is the belief that peripheral palsies recover soon and for that reason do not give these accidents proper attention.

The medicolegal question may arise here as to the liability of the surgeon if he has not taken all the precautions protecting his patient. Hence, it is evident that suitable prophylactic measures should be instituted before the subject becomes one of jurisprudence rather than medicine.

DISCUSSION.

Dr. F. Savary Pearce, Philadelphia—There is a woman under my care at the present time who has a post-operative paralysis owing to brachial pressure caused by the position in which she was placed during an abdominal operation. A point in etiology is, in part, as to whether the patient has a good amount of flesh cushioning her tissues; this woman was very slender, and of course there was less protection over the clavicle when the arm was extended.

The medicolegal aspect has also come to my attention, for in these cases the patients are inclined to blame the surgeon. The prognosis is very good in such pressure palsies. You are apt to find later, too, an exceeding amount of wasting and consequently a good deal of deformity, which brings the condition more to the patient's mind. It is here that we can give the surgeon a good word by promising a favorable prognosis.

Dr. Douglas Graham, Boston—I think a very common form is crutch paralysis, and if we get that in time there is almost an immediate relief through massage.

Dr. C. C. Hersman, closing—Even in the medical profession a great many men, instead of stopping to inform themselves, really think that the paralysis is caused by some mysterious effect of the anesthetic. Very often the man who is selected to give the anesthetic does not know that one position is more dangerous than another. Then if the paralysis does come on it is allowed to recover of its own accord, instead of Nature being assisted.

THE TREATMENT OF NEURASTHENIA.*

DANIEL R. BROWER, M.D., LL.D.
Professor Mental and Nervous Diseases, Rush Medical College, etc.
CHICAGO.

We have made great advances in every department of nervous and mental diseases, especially in pathology and diagnosis, but the least progress has been made in therapy. Those who are most active in the field of research seem to pay but little attention to this, the practical part. One of the best of our recent text-books on nervous diseases devoted twenty-six pages to neurasthenia, but only two to treatment. It is with the view of stimulating work in this direction and not with the idea of presenting anything novel that this paper is read, and with the hope that it may provoke a discussion that will be of service to us all in the treatment of this commonplace disorder.

Neurasthenia has always been regarded as a functional disease, with no pathology, but a flood of light has been thrown on it by the investigations of Barker, Hodge, Mann, Eve, and many others as to the effect of prolonged activity and repose, and the effects of intoxications on the neurons. These researches have enabled us to comprehend the pathogenesis of the clinical phenomena that are found in the cases that develop gradually from overwork, anxiety, fret and worry and those that result from autointoxication and other intoxications.

Neurasthenia is an exhaustion of those neurons, the effect of defective metabolism; it is a pathological fatigue arising most frequently from gastrointestinal autointoxication. The vasomotor mechanism is the first to show the effect and the degree of disturbance in vascular tension, as Weber[1] pointed out, is a great aid in prognosis.

Neurasthenia being pathological fatigue, the first indication for treatment must be rest, mental and physical, and the first difficulty in every case is to determine whether this should be absolute or partial. In my opinion very few of the cases require absolute rest and many of them are injured by it. If the case has been one of long duration and very severe, with a very low arterial tension with very pronounced dyspeptic symptoms, four to six weeks of absolute rest will be necessary, and this should be on the Weir Mitchell plan with isolation, massage, faradic electricity and special diet.

A partial rest is all the great majority require, and the amount must be carefully determined in each case. It is usually sufficient to have them retire early, get up late, and take one or more hours of rest at noon. This rest at noon should be in a quiet, darkened room, should be absolute, with as perfect a condition of muscular relaxation as possible; one hour may be sufficient, but two is better. I regard this noon rest as very essential and it is possible even with men in active business.

Equally important with rest is the dietetic management; indeed, rest and recuperation are the two things aimed at, and recuperation must come through digestible and assimilable diet. The diet should be largely nitrogenous, and in order to promote its digestion and assimilation, sugar and sugar-producing articles should be used in the smallest possible amounts. I am sure that beef, mutton and eggs should furnish the basis of the dietary, with milk, of course, when it agrees, and if sugar is cut off these foods are more perfectly elaborated. The predigested foods are of great benefit, for many of these cases with their want of tone in the digestive organs can not properly digest ordinary diet; and failure to recuperate is often due to this cause. Therefore, make much use of predigested food, giving special preference to malted milk and somatose, ordering a teaspoonful of the latter with a cupful of the malted milk, and this in the absolute rest cases may be given every two hours; in the partial rest cases between each meal and at bedtime. I think this compound is much better than milk in many cases. Caution must always be used in so spacing the interval between the feedings as not to overtax the digestive organs. While there is comparatively little danger of this in using predigested foods, yet I think mistakes are often made with ordinary foods in this way. We fortunately have many kinds of predigested foods, efficient as nutritive agents, but of such different tastes that we can usually satisfy the palate of the patient as well as serve the nutritive demands of the system. I do not agree with those who positively interdict the use of coffee and tea. On the contrary, I think they are beneficial in many cases, excepting those who have the excessive use of these articles as a part of their etiology. I fully recognize the fact that the excessive use of either of them aids in prolonging and promoting neurasthenia, but in moderation they are both conservative to the general nutrition.

---

* Presented to the Section on Nervous and Mental Diseases, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

[1] Boston Medical and Surgical Journal, May 5, 1898.

Electricity is the third indication. I have no doubt about its great value. In the absolute-rest cases, of course, general faradism is necessary, and I direct that in the beginning of the treatment it should be very gently applied and to the extremities only; later, to the whole body, using currents that can just be felt. The skin should be gently stimulated and the various groups of muscles should be made to respond to mild currents. The bed cases should also receive galvanism, first to the head, using a descending current with large electrodes of from 1 to 3 milliamperes; then to the cervical sympathetic, using from 3 to 5 milliamperes, and then to the spine and abdominal sympathetic, with a large negative electrode at the epigastrium and a smaller one over the spine and a current of from 5 to 10 milliamperes. These séances should be given daily.

The partial-rest cases who come to the office should have static electricity. I use it by insulation with the primary current, and by sparks from the spine and abdomen with the secondary current for fifteen or twenty minutes daily. My observation leads me to agree with Morton, Herdman and others that this form of electricity is sedative, tonic, eliminant and a promoter of normal vascular tension.

Hydrotherapy is the fourth indication. Sponge baths are a necessary part of the Weir Mitchell treatment, but in addition they should have the wet pack daily, beginning with a temperature of about 70 F., and gradually lowering to 50 F., prolonged for about one hour. The wet pack promotes tissue metabolism, favors the elimination of fatigue products and promotes sleep.

For the partial-rest cases, the dripping sheet is used, the water being about 70 F., and the friction with the sheet made vigorous, the whole rapidly done. It is an admirable vasomotor tonic. The shower bath, beginning with moderately warm water and gradually cooling it, is of much service in many cases. The hot-air bath, like the wet pack, will promote elimination and often overcome insomnia. Cabinets for this purpose are now readily accessible at a reasonable price.

Massage is the next indication, and is required in all the absolute-rest cases, and there is no necessity and but little advantage in introducing a special masseur. It should be given to the nurse, thereby not only saving unnecessary expense but averting the frequently distracting influences of a stranger in the case. It should be given very gently in the beginning, the movements being limited to the gentle and superficial ones, and little by little the force, vigor and extent of the treatments should be increased. The partial-rest cases sometimes need massage and sometimes do not. If the effect of the massage is sedative, it will do good; if, on the contrary, it is exciting or irritating and may do harm. In some cases, however, the difference between the effects may not be due so much to the patient as to the method of its administration. As the case progresses toward recovery, physical exercise becomes necessary. The Swedish movements may be added to the massage; light calisthenics may be provided, and such outdoor exercises as golfing, for example. This, I take it, is one of the very best outdoor exercises of to-day for the convalescent cases, and, indeed, for many of the mild cases from the beginning. One of the most persistent cases that I have ever had to treat was largely cured by golfing. The game was played near Chicago in the summer, and when the season was over, she went to the Hot Springs, of Virginia, on account of the golf links that were there, and later to Atlanta, Ga., and she returned home well. The reasonable use of the bicycle is of much use to many, always giving them the caution that its excessive use is dangerous. The trouble is that many of these cases do not seem to know when they have over-exercised. Horseback riding is a very valuable outdoor exercise, much less liable to be abused than bicycling. Change of scene is often of advantage, but much traveling is injurious.

The European trip has been very detrimental to several of my patients. A neurasthenic must be a very good sailor to derive benefit from an ocean voyage, and sight-seeing in Europe is hazardous to their nervous system. The climate selected should be one with a moderate mountain elevation, 1500 to 2000 feet, and one not too dry. Ideal places are to be found in the Allegheny mountains, especially in the mountains of North Carolina—the country round about Asheville, and even better the country north of Asheville, with Linville as its center. This mountain region has the proper elevation, is not too dry, is very free from fogs and has superb mountain roads and trout streams, and inspiring scenery, and far enough removed from the ordinary lines of travel to give the necessary quiet.

The sanitarium, for a short time, is a good place for some patients. They can here receive the rest cures at comparatively little expense, which is an important item, of course, with many; but I do not care to have them remain long in these institutions, because their association with other invalids may develop hypochondriacal symptoms in some patients and hysteria in others.

In the drug treatment of neurasthenia, the first important class is those which promote elimination. Autointoxication from constipation and colonic impaction are very frequently present, sometimes overlooked. The aloetic laxatives are those I most frequently use, such as the Lady Webster dinner pill, or the pill of aloin, strychnia, ipecacuanha and belladonna. Occasionally a calomel purge is beneficial. Many of these cases require colonic flushings with the normal saline solution administered in the kneee-breast position. Such flushings may be administered in the majority of the constipation cases once or twice a week to the very great advantage of the patient, not only relieving the constipation, but promoting renal elimination, so often deficient. This renal deficiency very often demands diuretics, of which the effervescing potassium citrate is probably the most efficient. All neurasthenics, I think, are greatly benefited by the imbibition of a large amount of water. This not only promotes renal elimination, but adds to the activity of all the emunctories of the body.

The next indication is to relieve the nervousness. For this purpose the bromids are invaluable, and I prefer the sodium bromid. This I usually combine with the fluid extract of adonis vernalis, in from 1 to 5 minim doses. This drug is a vasomotor and cardiac stimulant, and by reason of this action guards against the depressing effects of the bromid. It also increases renal elimination and is a sedative to the sensory nerves and has no cumulative effect. I very rarely administer the hypnotics on account of the danger of establishing a habit and because of their interference with digestion and tissue metabolism. The bromids during the day, the hot-air bath or the hot pack at night, with some easily digestible food at night will almost invariably secure all the sleep that is necessary. The blood in the great majority of the cases shows a low hemoglobin record and a low count of red corpuscles, and hematinics are necessary. Blaud's mass, first introduced to the profession by the great Niemeyer, combined with small doses of the extract of nux vomica and arsenious acid, makes the best hematinic combination that I have yet found and is vastly superior to any of the new iron preparations that I have tried. There are very few cases in which it will not rapidly improve the blood record. Cases that are not improved often require alteratives in addition, and the chlorid of gold and sodium, combined with the pulverized resin guaiaci, a combination that prevents the decomposition of the gold salt, given before meals, a half or three-quarters of an hour, is the best alterative combination in my experience. Occasionally small doses of the corrosive chlorid of mercury answers next in preference as an alterative. Phosphorus, as the zinc phosphid, or the syrup of the hypophosphites U. S. P., are of service in some cases, and the animal extracts containing phosphorus in a readily assimilable form may be used with advantage. The mineral acids in some of the dyspeptic cases, for temporary use, are of service. Quinin I rarely use unless there be a malarial element present. Strychnia I never give in large doses. I think these two drugs agree in increasing the nervousness and do not benefit, except in exceptional cases, general nutrition.

In conclusion, no matter what special line of treatment may be adopted, it is very important to keep the patient busy in his efforts at cure and a daily schedule of therapeutic work should be furnished to him.

DISCUSSION.

Dr. J. H. McBride, Los Angeles, Cal.—Dr. Brower's remark that neurasthenics do not know when they have reached their limit in work is true of all neurasthenics, or nearly all. Few of them have, or ever had, in health, the natural feeling of tire, and it is almost inevitable that they will overdo.

The mental element of the neurasthenic is an important one. The mere fact that we seclude them is evidence that this is considered important, and yet by seclusion not everything is gained for this side of their life. They should not be allowed to speak of their illness to the nurse, nor to any one. I have made it a rule to allow them to tell me their story once fully and then forbid them to repeat it. This saves the patient from indulging in the morbid luxury of reciting her symptoms, and by compelling a neglect of them they tend to become less prominent. The tendency to hypochondriacal states can be checked in this way.

Dr. W. S. Watson, Fishkill-on-the-Hudson—The importance of treatment of neurasthenia is more than the actual pathology, or whether it is functional or otherwise. The mentality of these cases is a very important feature. Very frequently they seem to live upon the idea that they have some incurable trouble. The electrical treatment and attention to the prevention of auto-intoxication from the intestinal tract are important. Mild doses of mercurials are of advantage, as in nearly all these cases constipation is a factor of no small importance.

Dr. Richard Dewey, Wauwatosa, Wis.—I find myself very much in agreement with the ideas expressed by Dr. Brower in his treatment of this common malady, especially the prescribing of a definite period of rest during each day. This is about the only method of preventing overtaxation in very many of these cases which we all encounter that are incapable of judging at all for themselves how much exertion they should make. They seem to have lost what you might call the fatigue sense. I do not know whether the fatigue sense has a definite center in the brain, but I have been struck by the fact that so many patients are incapable of judging the limits of their own strength.

I agree also in saying that treatment at a sanitarium has its disadvantages in bringing these invalids together, unless great care and precautions are taken to avoid undesirable association, with mutual comparing of notes and discussion of symptoms. This can be done, however, and if it is done, the oversight that can be exercised in a sanitarium is much superior to that which can be secured in any private house, unless you have a rest cure with one or two nurses constantly in attendance. In addition to tub and sheet baths I believe in different forms of sprays and douches, needle baths, etc., and also in the hot shampoo, which in many cases is exceedingly valuable in relieving insomnia.

Dr. C. C. Hersman, Pittsburg, Pa.—I have decided that rest is one of the best medicines for neurasthenia. Electricity and massage are particularly good with those who are put to bed. For those taking the rest cure I think the hot bath at bedtime is one of the best possible things, because it is such an excellent hypnotic.

Occasionally we find patients whom we diagnose as neurasthenics. Neurasthenia may be the beginning of a paresis; consequently it is necessary for us to study our patients closely. It may be very provoking for us to treat a case of neurasthenia, and then finally have it develop into a typical case of paresis. According to some of our best authors, we find that neurasthenia is the very first symptom, in some cases, and unless we study our patients carefully it is impossible to diagnose the beginning of paresis. In treating of neurasthenia one of the first and most important steps is to gain the confidence of our patient. Otherwise our success is not that desired.

Dr. John Smith—It seems to me that there are many cases that are diagnosed neurasthenia, and treated as such, which are not really that condition. Neurasthenia is not a distinct entity in itself, but it is simply a symptom-complex which we find in many disorders, and I think, not perhaps the neurologist, but the general practitioner, is too apt to simply discover symptoms and call it neurasthenia, without knowing what the underlying conditions are. I remember distinctly a case seen this year, which the physician had treated for some time, and finally sent to me saying he could not find anything outside of the neurasthenic symptoms. Immediately upon examining the urine I found the whole trouble. There was a large quantity of phosphates, and it was only a matter of three weeks before the woman was entirely well. I gave sodium phosphate and sodium benzoate combined with lithia salts.

Cardiac cases are often misunderstood and not treated properly. These are the cases which do so badly when we send them to the seashore.

Dr. Douglas Graham, Boston—I think it is generally conceded that electricity can be left off in neurasthenia. As to the massage, it depends of course upon how it is done. In these cases the indications are very definite for the use of massage, as it is almost sure to produce sound sleep if properly given in the evening to neurasthenics who have been wakeful. But if neurasthenic patients who sleep well without massage are masséed in the evening they are sure to be wakeful after it, and yet they do not feel the loss of sleep next day; they have gained something after all.

Dr. A. E. Sterne, Indianapolis—It seems to me that it is utterly impossible, in a condition like neurasthenia, to lay down a set rule for any case or even the majority of cases. It is rather a condition, a state of things, than a disease. A great number of cases of unquestionable neurasthenia in their beginnings pass to more profound conditions, both of neurosis and psychosis. From the early beginning the possibility of confounding the condition with the milder grades of paresis ought to be kept in view. I do not see so much resemblance between melancholia and neurasthenia as between incipient paresis and neurasthenia.

DR. DANIEL R. BROWER, closing—The hot-air baths and the hot pack meet the very important indication of elimination by the skin, and are both sedative to the nervous system. The hot pack should be given on a lounge close to the bed, so that the patient may be placed in the bed without exposure. As to electricity, one of the mysteries of the times is the fact that we have so many in the profession who fail to realize the curative power of electricity per se, and refer its effects to suggestion alone. Yet these same persons must recognize its great economic power; the electric light, the telephone and the automobile must constantly force this upon them, and then they must recognize its power to decompose water, and destroy tissue. Even regarding it as a purely suggestive agent, I ask those who decry its use, what more convenient agent of this sort can you find? But I beg of them to consider carefully the physiological action of the several forms, in use, before they begin their suggestive treatments.

INTUBATION IN PRIVATE PRACTICE, AND ITS PERFECTION.*

J. TRUMPP, M.D.

Privat Docent for Diseases of Children, University of Munich, Germany.

MUNICH.

You probably know that intubation was formerly received in Europe with great reserve, and also that the ingenious operation of O'Dwyer is practiced at the present time only by our clinicians. The reason why our practitioners have not much inclination for the endolaryngeal method is, that, being so conservative, they in this case apprehend that intubation is an operation immensely difficult to learn, and accompanied by a great number of dangers.

One who is experienced in the matter knows that these apprehensions are exaggerated, that intubation is not at all more dangerous than tracheotomy, and that its sphere ought not to be limited to the hospital. But prejudices of that kind, if they once exist, will not be removed by the reports of single persons, however splendid they might be, but only by extensive, thoroughly authenticated statistics.

In the summer of 1899 I took the trouble to procure data concerning intubation, and I believe with best success. I applied to 89 American and *European* authors, and that as well to friends as to opponents of intubation. What I learned was:

	Physicians.	Have done, Intubations.	Recoveries before 1894. Per cent.	Under Serum-therapy. Per cent.
In Germany	12	56	..	66
In France	8	437	39	77.11
In Galicia	5	165	30	89.9
In Italy	4	265	22.5	76.9
In Norway	..	..	..	..
In Austria	6	74	43	95
In Russia	1	4	..	100
In Switzerland..	3	18	42.08	100
In Spain	1	322	..	77.7
In Hungary	2	63	61	60
In Europe	42	1404	39.59	82.58
In U. S. A......	13	4066	31.5	81.5
Total	55	5470	35.54	82.04

These fifty-five reporters think intubation in private practice just as useful as in clinical service; twenty authors had no personal experience in the matter. The rest remained in decided opposition. It may be noticed that the latter ones together disposed of but seventy-three cases, seven of them never proved the effect of the operation in private practice. The common reason given for opposition was that the dangers of the after-treatment would be greater in practice; that therefore it would be necessary to keep the children under continued medical surveillance and that this very surveillance would be, under ordinary circumstances in practice, a matter of impossibility.

This apprehension was perfectly disproved by the reports of numerous well-experienced authors. There were reported but thirteen accidents: two deaths caused by sudden obstruction of the tube, 10 deaths caused by spontaneous detubage, and one in consequence of suddenly reappearing stenosis after extubation, absente medico.

My report given to the Gesellschaft fuer Kinderheilkunde at the Seventy-first Congress of German Naturalists and Physicians in September, 1899, stated, that: "the practitioner will have the same right—not to say obligation—to use if necessary and carry out intubation, and 2, the endolaryngeal method will give to him as well as the clinician much better results than tracheotomy.

The discussion following my essay proved that the number of opponents to private intubation was apparently reduced, on the face of these facts. Only one speaker emphasized the necessity of medical surveillance on consideration of the great dangers.

If we demand constant medical surveillance, intubation is out of the question. But at all events, we are obliged not to acquiesce with the results already gained, but to aspire to further perfection of the method, and this as long as intubation is accompanied by dangers, even very remote. On this behalf we ought to consider three points:

1. What common duties arise for the physician to undertake an intubation? 2. What method of technical execution is to be mostly recommended? 3. Which model of tubes hitherto existing is preferable to other ones, and is an improvement of the instrumentarium desirable and possible?

1. There is but one opinion about the first point: A physician should not proceed to the operation until he has sufficient previous practice on cadavers and animals. Besides he is to give instruction to the parents about the advantages and disadvantages of the bloody as well as the bloodless method; the alternative should be left to the parents. He should personally supervise the patient as well after introduction as after extraction of the tube as long as a momentary danger could be thought of. He should leave the patient only under the care of a reliable and well-instructed person, or nurse, and should never retire too far or too long from the patient.

2. As to the technique, it is rather indifferent how the tube is inserted if the operator succeeds in placing the tube quickly and without injuring the mucous membrane of the larynx in any way. It is a different question which caliber of tube is to be chosen. If the execution of the operation is a matter of manual ability the choice of the tube for the single case is the matter of clinical experience. Generally speaking one can say: If there are no especial indications to choose a tube of small caliber for the purpose of intermittent intubation, according to Francis Huber, tubes of that size are preferable which can just pass the larynx without being forcibly pushed in. The possibility of delicate introduction is always the condition sine qua non, otherwise the large caliber will be the best safeguard in preventing the most disagreeable drawbacks of intubation, sudden obstruction

---

* Translated and presented by Dr. Louis Fischer to the Section on Diseases of Children, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

and spontaneous detubage. Certainly another danger of intubation seems hereby increased: The danger of making a false passage. But this will occur very seldom if we do not injure the mucous membrane while inserting the tube, and besides we know no means now to prevent the danger. In the first place we are able to abbreviate the treatment by early injecting the required amount of antitoxin, and secondly we can use tubes of a material which will not be injured by the secretions of the mucous membrane, and vice versa will not injure the latter on its part. There is not much to be said about the operation itself. Manual ability and clinical experience are individual matters and will always call forth great difference in the results of the operators. But as to the instruments, the question is deserving of further discussion and a perfection of them might be for the general good.

3. Which model or kind of tubes now existing is preferable? As I know by my rather extensive international inquiry the opinion of nearly all the experienced intubators, I may define the question more precisely: Which model of O'Dwyer's tubes is preferable? The French tubes of Courts and similar ones may serve quite well in some cases, but they have not been received everywhere and this for good reasons.

Let us examine the models in proportion to the dangers of intubation. As to sudden obstruction it is rather indifferent which kind of tubes we use if we only take tubes with as large a lumen as possible and while introducing them avoid forcibly detaching membranous casts. The danger of detubage is best eluded by using tubes which remain in the larynx as firmly as possible. O'Dwyer himself has modified his tubes for this purpose providing them with a second swelling or bulge at the end of the tube. The effect is an excellent one. Spontaneous detubage happens rarely with these tubes. The third drawback of intubation remains—the danger of detubation. Here the material as well as the construction has to be taken into account. The tube must be of such quality that no harm is done to the mucous membrane in any way. So it must not have sharp edges and corners; it must be fitted as much as possible to the configuration of the larynx and trachea, it should not press nor irritate the mucous membrane.

In comparing the metal tubes of O'Dwyer with the model he last invented, the rubber tubes, we already see by simple theoretical consideration the superiority of the latter ones. The rubber tubes provided with the second swelling above mentioned will be very seldom coughed out; besides, being five times less heavy than the metal ones, they exercise less pressure on the mucous membrane, and finally they are made of a material which is very resistant to chemical influences and can be made very smooth. As not theory but practice decides in such questions I again undertook a little inquiry the results of which, with one single exception, were exactly what I expected. I used rubber tubes in six cases last winter and did not see difficulties of deglutition or obstruction, detubage or decubitus, though there were some severe cases.

Besides, I proved them in my course on intubation, introducing in adults at first the metal tube, without swelling at the end, for children of 13 years, afterward inserting the rubber tube of the same size. While the latter one remained in the larynx, even if there was violent choking, vomiting and coughing, the metal tube was always coughed out promptly. I had similar experience in my practice with children. The cause of this I see is the better adhesion of rubber to the mucous membrane.

To confirm my own observations I applied to Bokay, of Budapest, Bonain, of Brest, Dillon Brown, A. Caille and Louis Fischer, of New York City, Massci, of Naples, and E. Rosenthal, of Philadelphia. These gentlemen had intubated some hundred cases with rubber tubes, and state, excepting Rosenthal, that in using rubber tubes with suitably large caliber, accidents, such as obstruction, detubage and decubitus, occurred less frequently than with metal tubes. The reason for this is the light weight of rubber tubes, especially since the material does not suffer under the influence of the secretions of the mucous membrane as any metal will do. On this tube even in long use no concrements will be deposited which would injure the smoothness of the tube, and vice versa the mucous membrane. As a particular advantage of the rubber tube it is noticed by Bonain that they give less difficulties of deglutition on account of their light weight. Massei notes that in the new instrument set there are seven tubes instead of six, and so a better caliber will be possible.

Rosenthal alone reports bad results with rubber tubes. He noticed deposits as often as in the metal tubes. In 25 per cent. out of eighteen cases he stated decubitus, in three instances sudden heart failure. He also observed difficulties when he was ready to remove the tube on the fourth or fifth day. A decided reason for this he can not give.

Yet the reports of the other authors and of my own experience are so favorable as to the rarer occurrence of accidents as well as to the final results that we might dare to recommend the rubber tubes for common use. However, the report of Rosenthal requires us to act with great precaution and urge a further perfection of the instrument.

Commonly it is wrong to let theory speak before practice, but my propositions shall serve first to point out the weak points in our instruments, and besides I believe that if you, gentlemen, think my ideas good, you will be able to transpose them into practice quicker and easier than I can in this country.

I am of the opinion that very many lesions of the mucous membrane of the larynx, especially such done by beginners, originate in this, that the operation is still performed with an instrument entirely inflexible. If we should have the handle of the intubator manufactured in a material moderately springy, the instrument would have a certain latitude and could during insertion rebound better from an obstacle. Grave lesions, the forcing of wrong passages would be in future nearly impossible, as the operator would have his action better in control. Naturally the slide of the intubator, which is also now rather imperfect, would have to be omitted and the management should be altered in such a way that the erected index would lie on the obturator to regulate the pressure and to prevent an undesirable giving away. To give a support to the finger it would be necessary to broaden the obturator on its adjoined piece so as to level it on the top. Intubation would then resemble to a certain degree the harmless introduction of a hard-rubber probe.

We approach this idea still more if we also modify the construction of the tube. If you examine a rubber tube you will notice that the lower part of it occluded by the head of the obturator does not show a perfect rotundity. The tube's large end is horizontally cut off. The head of the obturator projects without transition like a long top, consequently it is undisputably more difficult to insert rubber tubes than the original metal tubes, because the former are much easier entangled by their broad bases especially in cases of cicatricial stenosis of the larynx. It can become almost impossible to introduce them, while probes even of large caliber can pass easily. For the same reason I *think the mucous* membrane will be lacerated by rubber tubes if the opera*tion is not carefully executed.*

The necessary modification is not difficult to be found. The lower swelling of the tube must be diminished so that the outlines will show a regular oval. The point of this oval is formed without transition by the head of the obturator. The lengthening necessary is insignificant. I hope I shall very soon succeed in demonstrating to you a model of it.

There is still another drawback to be removed, which is less important in rubber tubes, but as it could be the cause of decubitus in cases in which the mucous membrane is extremely *delicate it merits our full interest.* L. Bauer has first called our attention to the fact that the vertical axis of the trachea in children is deviating backward—to the vertebral column—from the axis of the larynx, and this the younger the child is. Bauer has limited his anatomical studies to the material in the children's hospital in Budapesth, and it is possible that his trustworthy though unconfirmed observations are confined to singularities of race of the Hungarian population. A deviation in such a high degree—168—will probably not be the rule in other countries. But as everywhere it is stated that next to the cricoid cartilage the anterior wall of the trachea corresponding to *the end of the tube is the favorite spot of decubitus,* it follows that the observations of Bauer must be correct, at least in a general way. Besides, you can ascertain on sections of the head that the end of the tube is riding on the anterior wall of the trachea so that in vivo there must be in speaking, coughing, and swallowing a continuous friction. Based on these observations, Bauer constructed proper tubes of metal. The vertical axis of these showed a considerable recurvation backwards; the ordinary swelling of the tube was lowered some millimeters also to avoid a pressure of the cricoid. These tubes are not yet in vogue and were not liked in the few clinics—Budapesth and Leipzig—where they have been used; above all, it was said that they were *rather difficult to* be inserted into the larynx. Yet it must be noticed that decubitus occurred with them less often. One can understand this, as the front part of the trachea is discharged and thus I propose to also give the rubber tubes a small incurvation backward from the middle swelling. This should not be as pronounced as in Bauer's tubes. The transferring recommended by Bauer of the middle swelling to the height of the first cartilage of the trachea I think a mistake, as thereby the tube loses one of its best supports and can rub against the cricoid more than ever whilst the larynx is ascending and descending.

Roussel's Sign in Incipient Tuberculosis.—The *Semaine Médicale* of November 28 states that experience has confirmed the accuracy of the sign pointed out by Roussel as an indication of tuberculosis in its early stages, namely, the sharp pain caused on light percussion in the subclavicular region between the clavicle and the third or fourth rib, originating 3 to 4 cm. from the median line and extending to and beyond the shoulder and the supraspinal fossa. Occasionally the subspinal fossa is sensitive to pressure. He attributes this cutaneous hyperesthesia to a reflex neuritis or myositis from propagation. In every case it is exactly over lesions of dry pleuritis in the apex. He has noticed it recently in a young woman who is a hysteric with absolute anesthesia.

TRAUMATISM DURING INTUBATION—ITS PREVENTION AND TREATMENT.*

DR. JOHANN VON BOKAY.
Extraordinary Professor at the University of Budapesth, and Supervising Physician in Charge of the Budapester Stefanie Kinderspitals.

In studying the literature of the O'Dwyer method of intubation we should really feel that everything that can be said in favor of or against it has been mentioned, and still we find a great deal requiring more careful elaboration; thus, the question of decubitus has not been given as much prominence as it deserves. True it is that all intubators must have found laryngeal ulceration resulting from pressure of the tube, and O'Dwyer, and later, Variot, the chief of the Trousseau Hospital, and his associate, Bayeux, besides Glover, Baudrand, and Marie Schultz, are among those whose attention has been directed to this particular portion of the subject. The French collective pediatric study of Grancher, Marfan and Comby on this subject appeared in a publication entitled "Laryngites Traumatiques Consecutives Au Tubage." This is the most valuable contribution to literature that can possibly be imagined. It seems as though the enthusiasts for intubation have been afraid to *publish* their clinical results, more especially their decubitus cases, owing to the fear of burying this valuable operative measure in the same manner as the Bouchut intubating method disappeared in the *fifties.* Let us hope that a careful study of this serious interference with the blessings of this operation will disappear and that the operative treatment of fibrinous laryngitis will be the same the world over as it has been in the United States, and that intubation will supersede the bloody operation of tracheotomy.

Since 1891 I have operated and observed more than 1200 intubation cases in the hospital under my immediate supervision. I had always noted traumatism following intubation in a series of cases, so that I now desire to lay this matter before you to encourage discussion.

Traumatism can result during the act of intubation in three *periods: during the introduction of the tube,* while the tube is in place, when the tube is withdrawn.

I *shall follow the classification* of Variot and divide this into three parts:

1. Traumatism may result "from denuding the mucous membrane or, in the formation of a false passage." Massei, the Neapolitan laryngologist, speaks of fracture of the tracheal rings during intubation. Slight lesions of the mucous membrane are mentioned by O'Dwyer, Jacques, Gillet, Valdemar, Damm, and Variot. If it is necessary to intubate often, and in short intervals, and that the mucous membrane will be injured repeatedly, then it certainly will be a serious matter for a laryngeal diphtheria in which the larynx already in a pathological state receives additional traumatic lesions. Such deep-seated lesions might result during the introduction of the tube if subglottic swelling or very thick pseudo-membranous masses obstruct the entrance to the tube. Hemorrhage has been known to occur in case of an abscess opened by the introduction of the tube.

2. Dillon Brown speaks of false passages, as early as 1887. He mentions two distinct cases ending fatally. In one, the tube perforated the ventricle of Morgagni

---

* Translated and presented by Dr. Louis Fischer to the Section on Diseases of Children, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

and got to the side of the larynx under the skin. In another instance, the posterior tracheal wall was penetrated so that the tube was between the esophagus and trachea. Rauchfuss, in 1890, speaks of four cases of "fausse route." Damm, 1896, saw in Paris one of Variot's cases of this kind, in which the tube perforated the ventricle. The number of cases in which false passages can be traced is very small. Trumpp does not believe this. Riss and Bensande, in 1896, describe two forms of false passage; in the one it begins behind the epiglottis penetrates the membrane thyrohyoidea, whereas in the second form the tube penetrates the ventricle, either directly or indirectly, through the vocal cord.

Heymann, whose investigations were conducted with Variot's material, saw three cases of false passage. In one case the tube was forced through the left glosso-epiglottic fold, and thus appeared through the tongue. In another case there was a perforation of the ventricle and lodged in the intercrico-thyroideal fold. Variot, in 1898, saw four cases of false passage among several hundred intubation cases. Besides three cases seen by Heymann, he saw but one case in which, as a result of the false passage an "ichorous phlegmonous abscess resulted." According to Variot, the false passage is usually made through the ventricle, and the tube with its introducer is usually pushed in the fold to the cricothyroid membrane, which it perforates. Among 1200 cases of intubation seen by me, four cases of false passage have been noted. They originated in the same year, and thus it is apparent that possibly the same hand that intubated caused these four false passages.

Case 1.—K. E., 22 months old, entered the hospital on Jan. 11, 1893, with a laryngeal diphtheria, and was intubated immediately. On the 12th the tube was expectorated; re-intubation very soon followed. On the 14th, 9 a.m., extubation with the string attached to the tube; at 10 p.m. the same day re-intubation was found necessary. At midnight of the 16th the tube was expelled, and at 4 a.m. was reinserted. On the 17th the child appeared asphyxiated in spite of the tube being in place, which required immediate extubation. It was found necessary to re-introduce the tube at once. At 10 p.m. the same evening the tube was again expelled, and a larger size tube inserted. On the 20th, 9 a.m., extubation, re-intubation in an hour. On the morning of the 23d the child pulled the tube out; asphyxia followed requiring immediate intubation plus artificial respiration. From the 11th to the 23d of January the temperature ranged between 38.5 and 39.7 C. The tube was *in the larynx in all 283 hours; there were 8 intubations* and extubations. At the post-mortem, on the right side of the larynx was a small irregular ulceration near the aryepiglottic fold surrounded by granulated edges, extending to the peri-laryngeal connective tissue, from which it extended anteriorly and downward. The mucous membrane on the right side of the larynx was filled with bloody granulation in the portion overlying the vocal cord, beneath which yellowish-red scars exist, showing loss of substance. The left processus vocalis is bare, and on the sixth to the ninth tracheal ring the mucous membrane and the perichondrium are missing. The formation of the false passage evidently took place on the 23d when the sudden appearance of asphyxia demanded rapid intubation; the severe and diffused decubitus in the larynx undoubtedly caused the false passage.

Case 2.—N. E., 3½ years old, entered on April 4, 1893: diphtheric stenosis is so severe that rapid intubation is called for—9 p.m. At 11 p.m. of the same evening the tube was expelled and re-intubated one-half hour later. On April 5, 6 a.m., tube was coughed out; the child breathed naturally without tube until 9 a.m. A sudden stenosis then made its appearance, demanding immediate intubation. A severe perichondritis thryeoidea followed. At 3 a.m. of the 6th the tube was expelled; re-intubation at 4 o'clock, without entirely freeing respiration. At 8 a.m. on the 7th the child drew out the tube, but the same had to be re-inserted a few minutes later. Respiration was scarcely any easier. On the 8th there was catarrhal pneumonia of the two lower patches. Death occurred on the 9th. The temperature ranged from the 4th to the 9th between 38.5 and 40 C. The tube was in the larynx in all 101½ hours. Number of intubations were 5.

Post-mortem: Perichondritis partis anterioris et processus vocalis sinistri cartilaginis thyreoideæ. Recessus ex sinu Morgagni dextro, in textum cellulosum prælaryngealem, inter lobos glandulæ thyreoideæ tendens. Decubitus *milium* æquans sub chorda vocali dextra.

To determine when the formation of the false passage took place, it is hardly possible in this instance, but considering that the symptoms of perichondritis thyreoidea appeared on April 5, the presumption is at hand that the false passage occurred during the first intubation. It is to be regretted that there is not a more detailed record as to the manner of the first intubation. We do not find any other circumstances recorded which would explain the perichondritis during the second 24 hours of the child's stay in the hospital, while the post-mortem examination shows that the decubital ulcer was in this instance only slightly advanced.

Case 3.—P. H., 5-year-old girl, entered on April 17, 1893, suffering with diphtheric stenosis. Intubation was made at 4 a.m. At 9 a.m. on the 19th, extubation; re-intubation at 5 p.m. At 9 a.m. on the 22d repeated extubation, but half an hour later the tube had to be re-inserted. At 6 a.m. on the 23d the tube was expelled; half an hour later immediate re-intubation necessary. At 6 a.m. on the 25th the tube was expelled, and the child breathed fairly well without it for three days. On the morning of the 28th, re-intubation; at 7 p.m. the tube was expectorated. Next intubation at 11 p. m. of the 29th. On the 30th, at 3 a.m., repeated expectoration; an hour later intubation, the child reviving with difficulty. The tube was again expelled at 7 p. m. At 1:45 a.m. on the 1st of May a sudden severe attack of stenosis, cyanosis and asphyxia occurred, continuing even after re-intubation had been effected. Shortly thereafter death occurred. The temperature ranged between 38 and 39 C. Intubation lasted 208 hours; number of intubations, 8.

Post-mortem: Perichondritis cartilaginis cricoideæ. Ulcus sinuosum ex sinu Morgagni dextro in textum cellulosum prælaryngealem tendens.

The false-passage formation in this instance probably took place on the night of May 1, when the alarmingly difficult breathing demanded immediate intubation. The ulceration of the ventricle Morgagni no doubt contributed to the formation of the false passage. The perichondritis cricoideæ may have originated from the ulcerated larynx.

Case 4.—R. G., 2 years old, was admitted on May 1, 1893, because of diphtheric stenosis; immediate intubation. Respiration became perfectly free. At 9 a.m. on May 3 the child draws out the tube. Symptoms of perichondritis *laryngea* were manifest. At 11 a.m. there occurred rapidly increasing stenosis, repeated attempts at reintubation, but without success. Tracheotomy *in asphyxia* was done. Following artificial respiration, and after the child had regained consciousness the *canula* was removed and a tube admitted into the larynx. At 6 p.m. the tube was expelled, followed by immediate re-intubation. Respiration became no freer. Death occurred. The tube was in the larynx 55 hours in all; number of intubations, 3.

Post-mortem: Recessus fabam æquans ex sinu Morgagni dextro, in textum prælaryngealem tendens, cum parietibus necrotis.

The false passage in this case was undoubtedly formed on May 3, when repeated unsuccessful attempts at reintubation were made. It also appears that as the patient had to be reintubated at 6 p.m., after expectoration, the tube got into this false passage, which explains why respiration would not become free. I am unable to explain the cause of the perichondritis, since its symptoms were already noticeable on the 3d.

Aside from Variot, only Heymann has made a thorough study of the symptomatology and diagnosis of the false passage. The diagnosis is made easier by one cardinal symptom, namely, that respiration does not become freer after the introduction of the tube, but on the contrary ceases entirely after a short lapse of time. On palpation at the entrance of the larynx, we find the head of the tube to bein an oblique position; in some instances we can even feel the lower end of the tube through the skin over the larynx, or on the side. After the false passage is formed, copious bleeding or bloody secretion may occur, if the tube is immediately withdrawn. Within a few hours after its removal, emphysema of the subcellular tissue may appear in the vicinity of the false passage. We take this opportunity of remarking that emphysema subcutaneum in an intubated patient can also result from alveolar rupture, as the two cases published by us in 1894 prove beyond a doubt. According to Variot, the tissues surrounding the false passage soon show symptoms of inflammation, and shortly thereafter an abscess forms on the side of the larynx—abscessus peri et latero laryngealis. The false passage may furthermore cause perichondritis thyreoidea and cricoidea, in which event the suppuration under the perichondrium often develops into pyemia.

There are no symptoms which would show a denuding of the mucous membrane. It is impossible to see them, excepting with the aid of a laryngeal mirror. It is frequently noted that hoarseness may result—so-called aphonia—long after the tube has been removed. This has already been mentioned in the third portion of my article. The prognosis of the *fausse route* is usually bad. Frequently it is mild and does not cause suppuration in the connective tissue or a perichondritis. Under normal anatomical conditions, we frequently find an opening covered by the perichondrium—the so-called foramen thyreoideum—which is about 1-6 mm. and through which the superior laryngeal artery frequently passes. If the end of a tube will enter into this fold by reason of a defect in the cartilage then a fatal hemorrhage might result owing to the perforation of the larynx. Where a distinct false passage exists it is hardly possible to expect a cure without performing tracheotomy. Heymann saw among the material of Variot, that after a false passage and the removal of the tube no stenosis of the larynx existed, and the child was able to breathe without a secondary tracheotomy, but the prælaryngeal abscess cicatrized very slowly, and the final healing was long drawn out. The simple desquamations of the mucous membrane, which are superficial wounds, have no real prognostic value.

The prophylactic treatment of traumatism resulting from the introduction of the tube requires a few words regarding the technique of the introduction of the same. Traumatism resulting from the introduction of the tube can also be caused by improperly constructed tubes, although the majority are caused by carelessness during the introduction. To properly intubate, we must be thoroughly acquainted with the details of this operation.

O'Dwyer has insisted on practicing on the cadaver, as well as on cats and dogs, in order to familiarize ourselves with the technique. I recommend intubating children that are not suffering with stenosis, but rather where a tracheal fistula exists. Palpation of the larynx through the mouth, also of the epiglottis and of the aryepiglottic folds. I first learned intubation on a child having a laryngeal fistula, and I make it a rule to instruct others in the technique by demonstrating the anatomy of the parts concerned on the living, and when they are proficient then I take them to a mild case of convalescing stenosis. O'Dwyer maintains that nothing is more erroneous than to believe that intubation of a skilled operator is a simple matter, and thus it is that a novice watching an expert will regard the operation as a simple matter. Waxham says that in order to obtain the most satisfactory results the operation should be performed only by those who by special aptitude and careful training are capable of doing it quickly, gently and skilfully; it is necessary to practice extensively so as to master all details. It is very difficult for those not having previously practiced. Thus, Dillon Brown says, I know of no operation in surgery which is more brutal and shocking than the efforts of an unskilful man to intubate. The position of the patient is an important one; next is the fixing of the gag, then the dilatation of the mouth. We can not put the tube in its proper place unless the mouth is stretched ad maximum. Heubner's method, quoted by Carston, allows the patient to be held flat on his back in bed. My idea is to follow O'Dwyer's method and have the patient in a sitting position. All details pertaining to the choice of tubes and the instruments must be carefully examined before commencing the operation. They should be boiled in a soda solution to render them sterile. Edwin Rosenthal, Philadelphia, insists on having the tubes plated after the use of the same. I should be glad to follow his advice. Before introducing the tube, it is well to wash the pharynx with a 4 per cent. boric-acid solution; "lavage antiseptique" of the French. Some use a carbolic acid and cocain solution, which I do not regard as practical.

Huber says it is necessary that the instruments should be worked in the median line. This is an important point, for as soon as the tube reaches the larynx, if we do not work in the median line we may enter the aryepiglottic fold or in the folds of Morgagni. Inexperienced operators usually enter the ligamentum epiglotticum medium between the root of the tongue and the vallecular line near the epiglottis. It is a good point not to push the obturator too soon, as otherwise we can damage the mucous membrane. The Bayeux-Collin instrument can not be compared with the O'Dwyer, as I have had no experience with the same. Thus I must repeat that a tube should be introduced gently and without force. Trumpp says that the hand must hold the tube gently, as though it were made of a very fragile substance. Although it is possible that in subglottic swelling the proper-sized tube can not be introduced; then it is our duty to introduce a smaller tube. Some authors contrast intubation with catheterization of the bladder, and compare the dangers of using force. Congenital stenosis of the larynx, as I saw in a child 14 months old, necessitated performing tracheotomy to prevent suffocation. The child died with symptoms of bronchitis crouposa, and the section showed that there was a congenital stenosis.

Dillon Brown, speaking of false passages, says that in the two cases which have come under his notice of false passages made in attempts at introduction, an unjustifiable amount of force was used to push the tube in place. In smaller children up to the age of 2 years, Gallatti has proved that the openings of the folds of Morgagni are so narrow that the end of the tube cannot enter therein. After making a false passage, it is the wisest to remove the perforating tube and to immediately follow it by a secondary tracheotomy.

Sevestre and Martin recommend the renewed intubation, but I do not believe that such an experiment can prove successful, as we usually enter the same false passage previously made.

Heymann says: *"S'il s'est produite une fausse route, la tracheotomie doit etre pratiqué pour permettre aux larynx de se cicatriser sans le contact d'un corps etranger."* Thus it is possible that without repeated intubation or a secondary tracheotomy healing may result. The possibility of producing a false passage may be a shady side of intubation, but let the opponents of the O'Dwyer operation remember that there are many more chances of producing a false passage, while performing tracheotomy. Marie Schultz says: *"on ne peut pas rejeter une méthode—à cause de l'inhabilité des opérateurs."*

DISCUSSION ON PAPERS OF DRS. TRUMPP AND VON BOKAY.

Dr. William M. Welch, Philadelphia—I have often felt that intubation in private practice is accompanied with much greater risk than in hospital; indeed, I have often wondered how a physician in private practice could give the necessary attention to a troublesome case. It is true that in the majority of cases of intubation after the tube is introduced no further attention is required until it becomes necessary to remove it; but there is a large number of cases in which there is much trouble. Frequently a child will cough up the tube as often as half a dozen times in a single night, and its immediate reintroduction is necessary. I can recall one or two instances, at least, in which death resulted because the physician could not get from his room in the hospital to the child in the ward quickly enough to replace the tube in the larynx. It is not uncommon, even after the speediest possible reintroduction of the tube, to find it necessary to resort to artificial respiration. I feel sure that such cases in private practice must terminate fatally.

As to the matter of the size of the tube, I would say that I find it necessary occasionally to deviate from the standard laid down by O'Dwyer. Sometimes it is necessary to use a smaller tube at first, and a little later it may be possible to introduce the standard size considered suitable for the age of the child. Again, the opposite may be true: The tube of the size supposed to be suited to the age of the child is coughed up almost immediately, necessitating frequent re-introduction, or the use of a larger tube.

I do not think there is much choice between the metal and the rubber tubes, although I am somewhat disposed to favor the latter because they do not collect chalky deposits. One might suppose that rubber tubes being lighter than metallic ones would be more likely to be coughed up, but this does not seem to be the case; indeed, I believe the tube is retained in position not so much by the weight as by the bulge in the middle of the tube.

About the only accident that I recall having seen in the operation of intubation is pushing down before the tube large pieces of exudate. This occurs every now and then, and always interferes with respiration and necessitates the hasty removal of the tube. If the exudate has been completely detached, it will be expelled. I have seen large and complete casts of the larynx, and even of the trachea, detached in this way and coughed up. We have in our collection at the hospital a beautiful cast of the larynx, trachea, both bronchi and several subdivisions of each bronchus, all in one piece When the exudate extends below the lower end of the tube, the latter will not, of course, be of much service. Even when it is detached and expelled it frequently reforms. False passages may be caused in the operation of intubation only by inexperienced operators. In regard to the injuries from extubation I would say that it is possible to do violence to the glottis if the beak of the extractor is permitted to open too widely. I have often thought that a serious difficulty might be met with if one blade of the beak of the extractor should happen to break off and drop down into the tube or trachea. I have never heard of such an accident. I have seen a disproportionately small tube drop down so low in the larynx as to be beyond the reach of the extractor. I recall two instances of this kind. In one case it was necessary to do tracheotomy, and in the other the tube was coughed up.

In one of the papers presented, I think the author referred to ulceration of the larynx caused by the tube. I have met with a few such cases and they all proved very serious. These ulcers are most liable to occur at a point in the larynx corresponding to the bulge of the tube, and at its lower extremity. The tube should not be worn any longer than is necessary, as it is a foreign body, and liable of itself to do injury.

With regard to the use of antitoxin in the laryngeal cases of diphtheria, I must say that my experience is not so favorable as that expressed by the author of the paper and most other writers. I am obliged to confess that I have been disappointed in its use. It occurs to me that it is scarcely fair to compare the results in intubation at the present time with the results before the days of antitoxin, since intubation is now more generally and skilfully performed. I believe that intubation is now done earlier in the disease than during the pre-antitoxin periods. In 1895 antitoxin was not as abundant as at present, and in Philadelphia we were obliged to rely on that obtained from other countries, more particularly Germany. During that year, it so happened that about one-half of the intubation cases received it and the other half did not, and the difference of death-rate was 3.39 per. cent. in favor of the antitoxin cases. In that year we limited its use to cases in the early stage of the disease. The far-advanced and moribund cases did not receive it, and this may account for the higher death-rate in the non-antitoxin cases. Our death-rate at the hospital since then, in intubation cases which received antitoxin has varied annually from 58 to 68 per cent. In 1894, the year preceding the introduction of antitoxin, the death-rate was 75 per cent., much higher, it is true, than it has been since; but diphtheria in 1894, as every one knows, was exceedingly severe in every country, and the death-rate was higher than it has been since, or than it was for many years preceding that date.

We have lately had at the hospital a great deal of unpleasant experience with croup in measles. I never before saw croup so fatal. The question is: Is it true diphtheria? Sometimes the Klebs-Loeffler bacilli are found, and sometimes they are not. In many of these cases the croup appears quite early —before the rash has disappeared—and intubation is required. This operation relieves the stenosis, but death almost invariably occurs. I do not think that this form of croup is necessarily the result of the formation of a diphtheric exudate. I have seen exudate on the tonsils, but frequently it is absent. It has been found post-mortem in the larynx. I think that in some of the cases the stenosis is due to intense congestion and swelling of the mucous membrane of the larynx, causing a spongy condition which, in the child, is sufficient to interfere with respiration. I could cite two very perplexing cases in which we found it impossible to get rid of the tube. Even after 4 or 5 weeks, on moving the tube severe and dangerous symptoms of stenosis appeared, necessitating its immediate reintroduction. Tracheotomy was at last performed, and in the case which survived we now find it impossible to do without the tracheotomy tube. I wonder what the ultimate result will be.

Dr. J. E. Rigg, Wilkinsburg, Pa.—What Dr. Welch has said regarding the advantages of hospitals in intubation cases is certainly true, as private practitioners know only too well. The best that we can do is to secure a competent nurse, train her in the care of intubation cases, and have such a nurse in constant attendance on these cases. My own experience with the tube has not been as satisfactory as has been generally reported. The cases have not been relieved, because, as I believe, the membrane has extended below the tube. I have had casts of membrane discharged, yet the symptoms would not be relieved.

Many cases receive antitoxin too late to expect good results.

My own use of antitoxin has been favorable, with two exceptions, and these cases received it too late. I know of a physician who gave a death-rate of 40 per cent., and it was explained by the fact that antitoxin was administered too late in every instance. I believe antitoxin has reduced the death-rate very materially, and if given early enough the results will be much better than in the past.

DR. A. CAMPBELL WHITE, New York City—Before we used antitoxin, for a period of six or eight months we kept very careful statistics of our croup cases, including, of course, intubation cases. We were able to save about 50 per cent. of our croup cases, which was much better than we had ever been able to do before. Only a small proportion of these cases were intubated, for at that time I did not think it wise to intubate a case unless it seemed absolutely necessary. Because of this, although we had a very high mortality in our intubation cases, the mortality-rate was very good in the croup cases as a whole. I was unable to save over 20 per cent. of my intubation cases at the hospital under this rule. Of course, in private practice one could not wait until the last minute to perform intubation, it being necessary often to intubate as soon as called in to see a child. That difficulty seems to me to have been overcome by the use of antitoxin. I believe now in intubating early—in*tubating* any child having even a moderate stenosis, and using antitoxin as well. I am of the opinion that the greatest benefits *from* antitoxin have been in the intubation *cases.* Before *the* use of antitoxin in New York City I feel sure that intuba*tion* was *generally* used; *at any rate,* I personally saw a great *many* cases of intubation before the use of antitoxin. Even *though the figures* quoted may not be very much in favor of antitoxin, *it is rare to see figures* speaking *against* antitoxin. *The* epidemic may be very mild one year and severe another, or *other* factors may enter to vitiate the statistics. I feel that *any one who has seen much* of diphtheria treated, both with and without antitoxin, must feel that he sees something happen in the antitoxin cases that he never saw before the days of *antitoxin.* I never used to see a child, apparently very ill with *diphtheria* one day and almost well the next, but I do now under the use of antitoxin. I remember one day when giving a demonstration in the diphtheria wards to a class of students a case of diphtheria came in, a child of 5 or 6 years of age. The little girl was apparently dead. We *inserted a tube, and* performed artificial respiration. This was before the use of antitoxin. In a few minutes the *child had recovered, and be*fore the students had left the hospital she felt like *sitting* up in bed. These students were deeply *impressed, and felt that* intubation would save that child, but I told *them that in* spite of the favorable appearance just then I thought the child would not recover, *and this proved* to be the case. The child *died of septic pneumonia.* This does not happen now, for the *use of antitoxin seems to have entirely* changed the character of the disease, *that is as to almost* constant development of *septic pneumonia.*

I *have never seen* or known of a case of false passage from careless intubation. I have frequently pushed down membrane before the *tube in my* hospital cases, and with one or two exceptions, tracheotomy has been *demanded.* *I recall one* case in particular in which intubation was *performed* by my assistant, who was an expert intubator. The tube was immediately withdrawn and tracheotomy at once *performed, and* although the membrane did not extend farther than the bifurcation of the trachea we were unable to save the child. I think even when the membrane does extend far down relief is afforded by intubation because most of the stenosis is usually at the vocal cords. There is *a typical kind* of dyspnea which we get when the membrane extends down into the bronchi; it is more like the dyspnea observed in *pneumonia rather* than in simple stenosis of the larynx. Relief is afforded by *intubation,* though death ensues. The tube does *occasionally* fall down between the cords; but it is *an accident* which should not occur, as it is the result of using too *small* a tube. A case like the one referred to by Dr. Welch, in which the tube was coughed up, probably would not be met with more than *once* in a lifetime. The tube turns and can *not be* extracted in the usual manner; hence tracheotomy is demanded.

DR. LOUIS FISCHER, New York City—You will all probably remember the great ovation given to O'Dwyer in Berlin at the Medical Congress in 1890. At that time tracheotomy was quite generally used, so that I think Dr. Welch was wrong in saying that antitoxin and intubation came into general use about the same time. He is *correct, however, in stating* that both antitoxin and intubation are to-day used far more extensively than formerly. I *make it a rule to treat a* case of diphtheria as diphtheria, and to treat a case of so-called septic diphtheria as septicemia. Two days ago the statement was made here by Professor Vaughan that it was useless to give milk containing toxins which had been subject to the process of sterilization, for the toxins had remained undestroyed. *He* illustrated this point by saying, if you gave 1/50 grain of this toxin to a rabbit, death would be instantaneous. *In the same* manner he claimed that we could not destroy the toxins though able to kill the germs, so we know that there are some forms of diphtheria—especially this septic *type*—in which, although the Klebs-Löffler bacilli are destroyed there is an overwhelming of the *system* with the toxin. *The result is the occurrence* of paralysis and other complications, if not death. In such cases one might just as well inject plain *water as antitoxin, as these* cases are true toxemic conditions, yet these cases are include
in the statistics of antitoxin. I make it a *rule in a seve*
case to give one large dose of *antitoxin—3000 units—and if i*
provement is not observed in twenty-four hours, this dos
repeated. If, however, after the first injection I find the
brane is being shed and the general systemic condition
proving, the dose is not repeated. I look *upon antitox*
remedy or a drug, *and I want to get* the systemic eff
it just as I would from rhubarb *or castor-oil.* I s
to ask Dr. Welch, and also Dr. White *whether it*
that a pure, simple uncomplicated diphtheria wi
stenosis, even though *most malignant, will reco*
with antitoxin, and if also the opposite is not
though you may inject antitoxin *and intubat*
variety of laryngitis complicating *measles* pro
spite of *antitoxin.*

e patient begins to walk, and *may have to be removed.*
ny considerable *tear* in the capsule should now be
closed with catgut. Drainage is usually unnecessary,
but if the blood-clots were so very adherent and the joint

much manipulated, so that considerable effusion of serum may be expected, drains can be used for twenty-four hours. They can be laid at the side of the joint, close to some of the lacerations, so they may drain the joint without actually being placed in it.

In closing the wound the stitches should not be carried entirely through the tissues and the skin, as this would carry any infection remaining in the latter directly into the joint. Some of our most successful operators make a deep line of suture and report cases where marked infection occurred, with deep burrowing among the muscles, but in which the joint entirely escaped. Antiseptic dressings are applied, and a firm bandage, running high, to prevent spasm. A carved wooden splint placed on the under surface answers every purpose until the drain and stitches are removed, when light plaster-of-paris is usually applied. Surgeons are constantly shortening the period of complete rest after this operation, and I should not be surprised if, in the near future, the patient would be permitted to move his leg as soon as the external wound has healed. Even now, Phelps, of New York, makes passive motion at the end of the third week. When treated by long rest, either with or without operation, the joint is exceedingly stiff for months after the injury, and it requires great persistence, with massage and forced motion, to fully restore its usefulness. It has recently been claimed that examination by the Roentgen rays shows that in some cases, after wiring, bony union has not occurred. This may be an error of observation, as the rays would here have an unusual opportunity for penetrating the new bone, but if the union in these cases be not bony it is quite as good, "as it is strong and unyielding, rarely breaks and never stretches."

A little less than two years ago, Dr. Darnell, of Atlantic City, N. J., fell from his bicycle and fractured his patella, and ten days later I wired it. The operation was particularly difficult, owing to the lower fragment being very short and having a bevel that nearly paralleled the hole I proposed making; and, in addition, that same lower fragment had a horizontal split that completely separated it into an upper and lower portion. By splitting the tendon and starting the hole there I was able to grasp enough bone to give a satisfactory hold. The rest of the operation presented no difficulties and he made an uninterrupted recovery. Owing to the condition of the fragments, I felt obliged to keep the leg at rest longer than usual, but he has succeeded in getting full and complete motion, and I am unable to find any difference between the motion of the damaged leg and its fellow.

DISCUSSION.

Dr. Donald Maclean, Detroit, Mich.—We were taught that there was a vast difference between an open fracture, a simple fracture and a compound fracture, and that it made as much difference as there is between night and day whether a fracture was subcutaneous or not. We were also taught that a subcutaneous operation for an abnormal condition was all right, but that an open incision was extremely dangerous. Now, we cut right down and see exactly the condition of the tissues we are dealing with and perform a complete and safe operation. Such is also the case with fractures, which do not carry with them the terrible feeling that they did a few years ago. By our aseptic precautions we can avoid the dangers of compound fractures. In the next place these same facts encourage and justify us in converting, at our discretion, a subcutaneous fracture, dislocation or injury into an open wound where you can see and feel the exact conditions. In this connection the X-ray has been of great advantage. A surgeon who would have proposed a few years ago to cut down and wire the fragments, or to open an elbow-joint or hip-joint which had suffered some obscure injury, would have been considered guilty of malpractice, but in these days of aseptic surgery we do not hesitate to cut down. When we have some obscure elbow-joint or hip-joint injury where there is some obstruction to replacement, if we can not succeed otherwise, we take our knife and cut down and find the exact condition present. The last, but probably the most important, aid in this work is the X-ray and no man would undertake to open an elbow- or hip-joint unless he had first made use of this means of diagnosis. In that way he will either justify his further procedure or obviate it, and if he decides to operate he would have some idea of what he was going to do. These great principles have been well illustrated this morning. Take for example asepsis; we no longer lay down a dividing line between open and subcutaneous operations. We do not have to let a patient go through life a cripple from an improperly treated fracture, as we feel at liberty, either with or without the X-ray, to lay the parts open and to do intelligently what in former times was considered very dangerous. The work done to-day will always stand as proof of surgical advancement.

Dr. J. D. Blake, Baltimore—I was very much interested in Dr. Barton's remarks concerning fractures of the patella and thoroughly agree with him in regard to what he says is absolutely necessary, i. e., thorough asepsis in connection with the opening of the knee-joint. I do not agree with him, however, in the means or methods which he uses in ascertaining the extent of damage done to the tissues around and about the point of fracture. He states that by placing his finger over the surface of the bones he has been able to determine what the fractured surface has been, to a large extent, if not completely covered by intervening fragments of tissue. This is very true and is the reason why we do not get bony union in these cases when not operated on, a fragment of tissue having fallen between the separated fragments; nothing but an open wound and the removal of the fragments of tissue will ever enable us to bring the bones absolutely together. I do not think that any man should use his finger in the wound, notwithstanding the fact that every aseptic precaution may have been taken and the wound made a thoroughly aseptic one. In operating upon these cases I never allow the finger to enter the wound at all. Nothing but absolutely sterilized instruments are permitted to enter the wound; I take up the fragments and cut them off close to the edge of the fractured bone with forceps and scissors. I have operated three times within the last two years without a wire. I do not believe that the patella is different from bone elsewhere. I believe its capacity for union is the same, and if the obstructing material is removed and the bones are brought in a position under the eye and fastened together thoroughly by sterilized ligatures, taking up the connective tissue and periosteum overlying the patella, stitching it together as recommended by some one whose name I cannot recall is all that is necessary. As in cases of fracture of other bones, we bring the bones as near together as possible. With your stitches taking up the tissues above and below the point of fracture, you will be able to bring the bones in thorough apposition, and by removing all fragments of tissue between them you will get good union.

Nor do I agree with the Doctor that it is better to wait eight or ten days before operating. I operate as early as possible after the injury, and by so doing am enabled to more easily get rid of effused fluid in the joint as well as the blood-clots, which are more easily dislodged early than later. I thus avoid the swelling, etc., which the Doctor wishes to get rid of after it has occurred. I accomplish the cleansing by washing out the joint with absolutely sterile water. Adherent clots are removed with dressing forceps; the finger and hand are not allowed to touch the parts under any circumstances.

Dr. M. B. Tinker, Baltimore—I would like to mention aluminum bronze as a possible suture material, not only for the patella but for bone in any portion of the body. This was first used in Germany in 1895, and I believe is now in almost universal use in that country instead of silver wire. The advantage of it is that it is gradually absorbed. I presume you are familiar with the fact that aluminum is dissolved by some of the fluids of the body. The aluminum bronze consists not only of aluminum but a small amount of copper, as aluminum alone has not sufficient strength; with the copper it makes very fine material for such work and does not absorb rapidly. In the case of Dr. Keen in which he used the bronze it could still be seen by the X-ray a year after. The effect of the secretions upon it would be to reduce any sharp edges. The Germans consider it superior to silver wire.

DR. A. J. OCHSNER, Chicago—In discussing Dr. Barton's paper I would state that my experience covers only seven cases, in three of which I secured perfect union. In many of the cases that come late for operation a blood-clot will be found between the portions of bone, and this is one reason why I would prefer a transverse incision rather than a longitudinal one. In suturing the patella I like chromicized catgut, because you never have to remove it. The patella being a sesamoid bone and being in the middle of a tendon, the important injury consists in a transverse tear of a portion of this tendon on each side of the patella. This tear can be sutured by a transverse incision, but it is much more difficult through a longitudinal incision. The operation should be performed with an Esmarch constrictor upon the thigh and this constrictor should be left in place until the patient has been placed in bed with the limb strongly elevated, thus preventing traction upon the patella. I believe that everything can be removed without placing the finger in the joint and I consider this important. Two of my cases were unusually interesting. One of them came in with a fractured right patella. Two years before the same patient had fractured his left patella. He went to work in four weeks after the operation, and in two months his leg was perfectly well, while the left leg is still defective, now five years after original injury. I usually let my patients walk in three weeks. I recall another case in which there was a compound fracture due to the kick of a horse which struck the center of the patella. The patient walked in three weeks and went to work in six weeks. I always prefer to operate at once and have at different times operated on the same day, the second day, or even an hour after the fracture had occurred.

DR. W. J. MEANS, Columbus, Ohio—In a paper read before the Ohio State Medical Assocation in 1899, I reported several cases of fractured patellæ treated by the open method, with uniform success. I regard the open method, when there is considerable divulsion of the fragments, as the proper procedure. I used in my first case silver wire to suture the fragments. In my later operations I have discarded the bone suturing entirely. After thoroughly cleansing the space between the fragments, removing the debris from the capsule, and trimming off the shreds of tissue that are liable to prevent perfect coaptation, I suture the margins of the capsule on the anterior and lateral surfaces with catgut, and close the incision without drainage. A posterior splint to the leg and a figure-of eight bandage complete the operation. While I am not wedded to any particular form of incision, yet I prefer the longitudinal one. Bone sutures are in my judgment unnecessary. Drilling the fragments requires considerable manipulation of the parts, which increases the danger of infection. Permanent sutures, such as silk or silver wire, are liable to cause trouble at some future time. Kangaroo tendon and catgut cut on the sharp corners of the bone, and therefore fail to give the desired effect. The main points in favor of the open method are: 1, perfect apposition; 2, bony union; 3, saving of time; 4, complete restoration of the function.

As to the question of opening joints to reduce dislocations, I believe it is a legitimate and scientific procedure. Four weeks ago I opened a shoulder-joint to reduce a dislocation of the humerus that had occurred three months previously and had resisted the efforts of several good surgeons to correct it. The result is perfect. I believe operative procedure for the correction of irreducible dislocations and for the correction of fractures where the fragments can not be properly adjusted, are legitimate and scientific.

DR. RANDOLPH WINSLOW, Baltimore—I have several times opened the articulation for dislocation of the elbow, and I have found that even when this is done and the parts are thoroughly exposed it is still by no means easy to reduce the dislocation. I am glad to hear that reduction has been more satisfactorily effected by using double lateral incisions than by a single incision. In several cases I found it necessary to divide the triceps tendon.

DR. HART, China—I have been in China for the past seven years and many such cases have come under my notice, several of which I have operated on. As far as fracture of the patella is concerned we see very few such cases, only three or four having come to my attention. I have had to adopt different methods at various times and have operated on some by using the subcutaneous suture, which has been satisfactory, provided the limb was properly supported with a plaster-of-paris splint. I have also used sterilized silk for stitching the fascia and the tendon together, thus bringing the bones in apposition. It is very difficult to keep the patients quiet unless you tie them down in bed. In one case, a fracture of the femur, where it was necessary to keep the man quiet, I told him he would have to stay in bed several weeks, but he got up the next day, and I then chained him in bed. There are a great many joint diseases in China, and I have operated on a considerable number, particularly for necrosis of the head of the femur. Operative procedures give the most satisfactory results in these cases. I see quite a number of old cases of dislocation of from one to four months' standing, but it is very difficult to get the consent of the patients to operation. We always try to reduce the dislocation, and in many cases have been successful, but we have found dorsal dislocation of the femur the most difficult. We must first get the consent of the patient, and besides that we have to keep a book in which they sign their names, agreeing not to hold us responsible.

DR. J. W. MACFARLANE, Pittsburg, Pa.—Dr. Barton's paper is an advocate for wiring these cases, as against the ordinary splint plan, and the Doctor indicated that all cases should be operated on. I grant you at the beginning that the open method is a much better treatment, but still it can not be denied that a small portion could be treated by the splint method. In view of the fact that these papers are spread broadcast, I think the general practitioner should have a chance for his "say." It is possible for a man to get good results without the open method. There is one objection to the paper, namely, the statement that the operation is a difficult one, for I do not think that anybody will agree with him. I take it that when we advocate a plan of treatment we should make it as easy as possible and it does not add to the weight of our views to state that the matter is difficult. So far as asepsis is concerned, of course no one would touch a joint except under strictly antiseptic precautions. As to the linear and transverse operation, I believe it is better done by the transverse.

DR. J. M. BARTON, Philadelphia—I did not intend to say that I introduced the unprotected finger into the joint. The broken surfaces of the patella are turned up before us and they can be seen and felt without going at all deeply into the joint. Personally I always wear rubber gloves in these operations. In my experience sepsis has been limited to one case, and this did not start in the joint, but in the skin. As to removal of the silver wire, I have never had occasion to do this, and if it is carefully buried at the operation I think it is rarely necessary.

Some of the speakers have strongly advised absorbable sutures and sutures which do not penetrate the bone. This I am not prepared at present to accept, for as I understand it, in order to get bony union without long-continued treatment, and with a freely movable joint it is necessary to make passive motion and walk on the limb long before bony union has taken place. The suture, therefore, has to be strong enough not to break and so applied as not to stretch or tear out. I have never had the slightest trouble with the wire suture penetrating the bone, and I see no reason, when we have risked the patient's life and limb by operating on the joint, to take any chances on the suture being ineffective. If time and experience show that some absorbable suture will act thoroughly and efficiently, I am certainly willing to accept it. As to operating on all cases, I stated that if the patient is in good health, other things being equal, I preferred to do so.

Dr. A. D. Bevan, Chicago—I may be criticised for taking the position against the open operation for fracture of the patella, but I have found that by non-operative treatment I have obtained good results. I have one case, a prize-fighter, who has fought several times since his accident, who fell from the gallery of a gymnasium backward, sustaining a fracture of both patellæ. These were handled in a conservative way, bringing the fragments together with adhesive plaster, which was changed every few days, and we have obtained such good union that the man has returned to his old line of work. I have also treated a golf player in the same way, and since the accident he plays as well as ever. I do not agree that the conservative method is unsatisfactory, for I have found it just the opposite. I have two cases of fracture of the patella handled in this conservative way in which the X-ray shows bony union has taken place. On the other hand, I have seen one death from operation and a number of cases of sepsis, and I would state that the ordinary medical man in general practice has no right to open up a simple fracture of the patella which he can approximate by means of adhesive plaster or plaster of paris. A man who has at his disposal all of the facilities for aseptic work has a right to handle his cases by the open method, but the vast majority of cases will fall into the hands of men who have not such facilities. The men who handle these cases should be taught to do so by the non-operative method and such a teaching would be of great service to both the patient and the surgeon.

GROWTHS IN THE FRONTAL SINUS.

TWO CASES; OPERATION; RECOVERY.*

W. D. HAMILTON, M.D.
COLUMBUS, OHIO.

Tumors in the frontal sinuses are not elaborately discussed by modern text-books on surgery. The diagnosis of this pathologic condition can not be well established until marked deformity is present. Kikuze published in 1888, a list of 54 cases in which tumors had been removed from the frontal sinuses, and of this number 18 died of sepsis, but the writer has not had access to any tabulated lists showing results of operations done in the last twelve years. In the face of a mortality of 33 per cent., it is obviously important that operations should be performed early in the history of the disease—as soon as the diagnosis can be made. These neoplasms may be either benign or malignant, and the osteomata are the growths most commonly met with in this location. They may attain to considerable size and sometimes undergo necrosis, and on account of the proximity of such a neoplasm to the brain and its meninges, there is danger of meningitis or cerebral abscess from its presence. Again, an empyema of the frontal sinus may complicate such a growth. When the operation is done, it is obviously important that rigid asepsis should be employed. Prominent among the pressure-effects produced by these tumors is the absorption of the cranial wall, or of the roof of the orbit, or of the wall of the sinus itself, or of the membranes of the brain contiguous to it. No classical incisions have been suggested for their attempted extirpation. If the tumor be large, it may be difficult, or impossible, to avoid a somewhat unsightly scar.

Case 1.—J. B. C., aged 36, a resident of Carpenter, Ohio, a farm laborer by occupation, was admitted to Mt. Carmel Hospital, May 21, 1899. His father died of cancer of the kidney, though the other members of the family were free from any constitutional taint. His general health had always been good, with the exception of an attack of typhoid fever two years prior to his admission. At the age of 14 he was struck on the forehead with a stick, causing a swelling at the root of the nose. This was incised, discharged a small quantity of pus and closed within a fortnight. The swelling never entirely disappeared, but continued to increase in size up to the time of his admission. The patient had of late suffered from headache and vertigo, and the forehead was the seat of an enlargement, extending from the line of the brows for some distance above the frontal eminences. Laterally it reached nearly to the angular processes. It was somewhat irregular in contour and more prominent to the left of the median line. Transversely it measured 3½ inches, while the greatest vertical dimension was 2¼ inches. It was in portions hard to the touch, while in many other places it yielded a kind of crackling sensation. He had no febrile movement, there had at no time been any purulent or bloody discharge from the nose or from either ear, and his mind and vision were not apparently disturbed. The forehead was bulged out, so that the deformity was readily discernible and very unsightly. A diagnosis of osteoma or osteosarcoma of the frontal sinus was made and operation was advised.

After thorough preparation of the head and face, he was operated on at Hawkes' Hospital, under ether narcosis. A crescentic incision was made, connecting the two external angular processes and reaching at its center a point about three inches above the root of the nose. The flap having been rapidly turned downward, Hartley's chisel was used for the purpose of dividing the bone beneath the incision. The frontal bone had been to a certain extent absorbed and thinned by the growth in its progress. The chisel was used below transversely in the hope that the neoplasm might be shelled out, but the mass was too firmly fixed to make this undertaking feasible. An ordinary amputating saw was driven transversely into the most prominent part of the tumor, to the depth of one-half inch, and at a distance of 1½ inches from the superciliary ridges. It was hard as ivory. Strong chisels were driven into the section made by the saw, and by the employment of considerable force the tumor was removed piecemeal. Rongeur forceps and large pliers were also used in the operation. The meninges were in some places exposed, while in other parts they had been absorbed, and the growth in its development seemed to have encroached backward, upward, forward and laterally as well. No formidable hemorrhage was encountered and, after having cleansed the cavity, it was packed with iodoform gauze and, provision for drainage having been made, the wound closed with stiches. The next day the patient had a normal temperature, no pain, and the dressings were thoroughly saturated with blood-stained serum. His convalescence was uneventful and he left the hospital in four weeks, with the wound healed. The growth was found to be osteoma, and weighed 4½ ounces. A recent letter, evidently dictated by his physician, states that his general health is very good and that there is no sign of recurrence. There is some depression in the forehead and at times he is annoyed with double vision. He is able, however, to go about his ordinary avocations without being at any time incapacitated.

Case 2.—C. S., aged 27, a resident of Wellston, Ohio, was sent to Hawkes' Hospital by Dr. J. B. Spencer, of that place, on May 18, 1900. A laborer by occupation, he had fair general health until the past few months. He first noticed a protrusion of the forehead three years ago, and it increased steadily in size until his admission to the hospital. There was no history of syphilis or tuberculosis. Some months prior to admission he consulted the writer, and then had headache slight impairment of vision and marked double exophthalmos. He was put on antisyphilitic treatment for tentative and diagnostic purposes for a number of months, but without improvement. At the time of his admission he had a bulging swelling directly above the nasal process of the frontal bone, the size of a walnut, and flattened slightly from one side to the other. He also had double exophthalmos, especially of the left eye, with ugly divergence. Dr. C. F. Clark found double optic neuritis, inability to read and threatened blindness. The ophthalmoscope showed, particularly in the left retina, a striated condition suggestive of edema, apparently the result of intracranial pressure on the posterior part of the eyeball, while on the nasal side a patch of choroiditis had developed from it. He was becoming dull and apathetic and at times had slight fever. There was no history of nasal or aural disease, and the sense of smell was unimpaired.

---

* Presented to the Section on Surgery and Anatomy, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

The diagnosis of tumor of the frontal sinus, probably osteoma, was made, and operation performed. An incision was made on the forehead, which exposed, after reflection of a small flap, the region of the expanded frontal sinus. Dr. William Todd, the dentist, rendered valuable assistance with a surgical engine. A hole was bored into the sinus and the anterior wall found to have been largely absorbed. The sinus was filled with what proved to be an osteoma, rather soft in consistency, and a structure was also found resembling a fibrous polyp. This mass was located exactly in the median line in the sinus in such a position as to interfere with proper drainage into the infundibula. As a result there was retention of mucus and pus, and both sinuses were filled with mucous polyps of varying sizes. The roofs of both orbits were partially destroyed, and the secretion, together with the polyps, mucus and pus, were in contact with the dura mater, which was carried so far backward that the finger could reach the petrous portion of the temporal bone. After the removal of the bony growth and the polypi, the cavity was thoroughly washed out with salt solution, which was used freely during the operation. The bone required rather extensive removal in order to get at the sinus, and the dental engine was very useful in dividing the bone. The wound was carefully packed with iodoform gauze, some of which was lodged behind the left eye, and was partly stitched, leaving ample provision for drainage in the median line of the forehead, in the location of the frontal sinuses. At this writing he has had a normal temperature for three weeks. Ten days ago he was anesthetized, some small sequestra were removed, and the edges of the wound brought together except at the lower median angle. The cavity is about closed. It is lined with granulations. His general condition is much improved. The opening in the forehead leads downward a distance of two inches to the space behind the left eye and an equal distance toward the apex of the right bony orbit. It would have facilitated drainage if a counter-opening had been made through the squamous portion of the temporal bone on the left side at a point opposite the cavity behind the eye.

Improvement has been very marked, and the indications are that the patient will get radical relief, although the sinus will no doubt persist for a time, until the cavity is healed. H mind is perfectly clear and he is free from pain, has no vertigo, has gained in flesh and is able to read ordinary print without fatigue. The exophthalmos has disappeared, and examination by Dr. Clark shows that vision is up to the normal, while the ophthalmoscope reveals a condition of things in which the choked disc has disappeared and the retinæ are about normal.

June 29, 1900: Patient was out of hospital for first time. Dr. Hamilton had operated April 20 and removed large growth—polypi—and pus. Patient has made a good recovery. Vision, R., 5/9, with + .5 S. = 5/75; L., 5/9, with + .5 S. ⌣ .5 C. ax. 90° = 5/6.

Diplopia occurs only with cover or with colored-glass test, which is overcome at once. Hypertropia is 0° in right, 4° in left; esophoria, 1°, abduction, 5°; adduction, 14 to 20 degrees.

Ophthalmoscope shows right disc normal; some fine horizontal striations of retina in macular region persist; vessels normal. Left disc appears normal; possibly slight paleness; some disturbance of epithelium about the disc, but not excessive; in the large area of choroiditis there has been increase in pigmentation; coarse horizontal striations still persist. No scotoma discovered in temporal fields, therefore retina is not destroyed by choroiditis.

The first case was one of large osteoma, as has been indicated, while the second was one in which an osteoma of softer consistency of the frontal sinus was complicated by the existence of polypoid growths and a rather extensive empyema.

DISCUSSION.

Dr. R. H. M. Dawbarn, New York City—An important point in these cases is the early diagnosis of the tumors, particularly when malignant and occurring in the frontal sinus of the antrum. I will mention one case to illustrate the point, which I saw five years ago. The patient had had persistent face-ache for a long time, and a dentist had extracted an upper bicuspid, the fang of which was quite soft, instead of being the normal hardness of the crusta petrosa. He came to me some weeks later, but had absolutely no evidence of a tumor so far as any bulging was concerned. By the electric light I could make out that the antrum was filled with something, and upon taking a round sewing-needle I was able to demonstrate that whereas the bone on the other side was of the usual extreme density, on the diseased side it was soft so that I could push a needle through it and into a solid growth in the antrum. Softening is quite frequent in these cases and greatly aids the diagnosis. By this method of pushing the needle into the tumor and its meeting with diminished resistance I have been able to make a diagnosis much earlier than I otherwise could have done. In an operation upon the frontal sinus we are able to do much better work and accomplish drainage more in accord with surgical principles by the natural passage by curving a probe in a peculiar way, which I discovered by experiment, and inserting a drainage-tube by a thread tied to the probe through the natural opening, instead of crushing through the bone from the frontal sinus into the nose for passage of a drainage-tube—which is the more usual way. Nine years ago I did a number of experiments on the cadaver, trying to effect drainage by the natural passages, first through the infundibula and then through the nostril, and I found by curving the probe in a peculiar way it could be done very readily. The drainage-tube is drawn through the nostril up into the frontal sinus. Dr. G. R. Fowler, in his article in Wood's "Reference Handbook" upon Frontal Sinus Disease, has an illustration showing how to curve the probe for this purpose.

TREATMENT OF THE GASTROINTESTINAL SYMPTOMS IN TYPHOID FEVER.*

J. M. ANDERS, M.D., LL.D.

PHILADELPHIA.

While we have no direct specific remedy for typhoid fever, and no knowledge of any drug that destroys the bacillus of this disease, the proper management of the gastrointestinal system, and especially during the early period, will prove of decided advantage. Among the principal objects met in this way is the preservation of the strength and vitality of the patient, thus probably inhibiting the virulence of the bacilli and their toxins, as well as that of some of the intestinal organisms which are otherwise harmless. Moreover, we can diminish somewhat the amount of intestinal toxins, and hence to an equal extent their absorption into the general system. The frequency of certain symptoms and complications—meteorism, vomiting, diarrhea—which are so very prone to manifest themselves if the prima via be neglected, may also be lessened.

Before discussing the usefulness of drugs in this condition, which I grant are subsidiary in importance to correct feeding, baths, careful nursing, and the judicious use of stimulants, I should like to call attention to the prophylactic influence of the first two, namely, feeding and baths. In the care and management of the digestive tract, correct feeding stands paramount. For the typhoid patient liquid nourishment—milk, broths, meat-juices, egg-white and the like—is the safest, as it is the best form of alimentation, as a rule. The liquid articles mentioned can be alternated with each other, although milk, when well borne and not too vehemently objected to, should be given throughout the entire course of the disease. Let me lead your attention to the importance of administering the same at stated intervals—every two or three hours—and in definite quantities—6 to 8 ounces at each feeding. As to quantity, however, this should be regulated with reference to the capacity of the gastrointestinal tract. For example, if meteorism or nausea intervene, or the stools contain curds or oil globules, or a marked increase in their frequency occurs, instead of having recourse at once to drugs, we can benefit the patient's condition much more by making a thorough investigation of the diet, particularly as to quantity and character, as well as of the condition of the dejecta. Peptonizing the milk if nausea occurs or it is not well digested, as shown on macroscopic or microscopic examination of the stools, and discontinuing beef and mutton broths if the bowel movements be too frequent, may render medicines entirely unnecessary. We may also diminish the quantity of all forms of alimentation for twenty-four or forty-eight hours, with marked benefit in some cases.

---

* Presented to the Section on Materia Medica, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

The Brand method of treatment has a favorable influence on the gastrointestinal tract, by reason of its action in reducing temperature, in lessening nervous manifestations, and imparting tone and vigor to the heart and the muscular system. The digestive functions are invigorated, the glands secrete their respective juices and the tongue becomes moist, sometimes clean, and the appetite improves. While the external application of water is productive of these happy results, the internal administration also has decided advantages for the sufferer.

Dr. Hector Maillart,[1] of Geneva, as the result of his study of the subject, states: "I feel convinced that the treatment of typhoid fever with copious drinks may be recognized as a definite method. In order that the treatment may be efficacious the patient should drink at least 5 to 6 quarts of water daily during the whole febrile period. There is no contraindication to this treatment; feebleness of the heart, so far from contraindicating the drinks, may become a special indication for them. The results are a progressive lowering of the fever, disappearance of the dryness of the tongue and mouth and pronounced sedation of all the alarming nervous, circulatory and renal phenomena. These results are due to the oxidation of toxins and refuse material, which are rendered soluble and eliminated. The oxidation is shown by the formation of great quantities of urea, and the elimination takes place by the skin and kidneys, in the form of profuse sweating and abundant diuresis. This diuresis re-establishes the integrity of the renal filter and that results in the rapid disapearance of albuminuria."

This method of treatment, however, does not have a controlling influence on the general course and duration of the disease. The quantity of water can be reduced to 2 or 3 quarts per diem, and administered, as Gilman Thompson properly advises, between the hours of feeding, so that the gastric juices will not be too much diluted. Again, in those cases of typhoid associated with a tendency to constipation, this form of treatment is found to be efficacious, producing, as I have repeatedly observed, free evacuations.

As the function of the stomach is much impaired, resulting in deficient secretion and diminished motility, meteorism is often encountered, due to decomposable material, an appropriate diet notwithstanding. To supplement the defective gastric secretion, I would advise the use of HCl in small doses after each feeding; this replaces the missing normal acid and acts as an antiseptic, thus preventing the multiplication of microorganisms.

To address antiseptic remedies to the bacillus of Eberth or its toxins, or to the intestinal lesions, would, I believe, be hopelessly futile; and the claim that clinicians have aborted the disease with these remedies lacks confirmation. Intestinal antiseptics, however, have a sphere of usefulness, exerting as they do an inhibitory effect upon the fermentative processes, thereby counteracting the offensive odor of the stools and arresting the growth and development of ordinary intestinal bacteria. Some members of the antiseptic class of remedies, being slightly astringent, also lessen the diarrhea.

It has been my habit, especially in robust individuals, to employ calomel for the first few days of the fever. Its action as a hepatic stimulant and disinfectant of the bowel is worthy of consideration. Calomel removes the decomposable material retained in the gut, and it "places the bowel in a favorable condition for the subsequent maintenance of antiseptics."—R. H. Quill.

For the constipation sometimes present throughout the entire course of the disease, I have found an enema of soapsuds, given every second day, to be followed by the speediest and best results; in late protracted cases accompanied with an irregular intermittent fever, I have seen good results follow the administration of divided doses of saline laxatives. Again, it sometimes happens that a diarrheal condition occurs during the early period of convalescence, due to some irregularity of diet or overabundant feeding, or to a bacillary—otherwise harmless—development, and under these circumstances a mild laxative is sometimes followed by prompt amelioration of the symptoms. In this connection I wish to protest against the routine use of the so-called Woodbridge treatment. I have never seen the gratifying results claimed by its author and his disciples. Moreover, there is no special medicinal treatment for typhoid fever, but there is for the individual case.

Of the group of intestinal antiseptics, salol, benzonaphthol, thymol, carbolic acid, etc., I commonly employ salol, the dose being 3 grains every three hours, or larger quantities, even if the symptoms are above the average severity. It is a compound of salicylic and carbolic acids, insoluble in the normal juices of the stomach, but the pancreatic secretion decomposes it into its constituent elements. Its action is that of an antiseptic; meteorism is diminished and the stools become less offensive, as I have often had occasion to observe. The other members of this group of antiseptic agents may be credited with the same action, but my personal experience with their use has been quite limited.

For the marked distension of the bowel, especially noted when the colon is the seat of the principal lesions and diarrhea is a prominent feature, turpentine is probably our best remedy; it is an efficient antiseptic and a stimulant to the circulation and glandular system. When the healing process in Peyer's patches is slow and sluggish, turpentine, by virtue of its stimulating action, hastens the repair of the typhoid ulcers. For the meteorism white turpentine or the oil may be administered internally; if the stomach becomes intolerant, then enemas of the oil combined with milk of asafetida are very efficacious. As turpentine is eliminated from the system through the lungs and kidneys, and on account of the overworked condition of the last-named organ, the drug should be used with great caution or discontinued on evidence of albumin in the urine. Dr. Pfromm informs me that in a recent case that he saw with a brother practitioner, the patient, being in the last half of the second week of typhoid fever, suddenly showed uremic manifestations while taking turpentine; the urine was scanty and contained both albumin and casts; some twitching of muscles was noticed. On discontinuing the turpentine, the urine increased in amount, albumin and casts disappeared in three or four days and the patient made a good recovery.

---

[1] Foster's Therapeutics.

The colon or lower bowel is sometimes the seat of extensive ulceration; this is productive of marked tympanites, and at times an exhausting diarrhea supervenes, or involuntary discharges may occur. In these instances, intestinal irrigation if judiciously employed tends to sweep from the bowel decomposable material and irritating micro-organisms. I sometimes combine with the water an antiseptic, as salicylic acid .5 to 1 per cent., or bichlorid of mercury 1 to 6000, used thrice daily, or every four hours, according to the urgency of the symptoms. If a decided catarrhal condition exists silver nitrate .25 to 1 per cent. may be advantageously employed.

The introduction of cold water into the rectum may also be practiced with happy results in suitable cases. It has other advantages than those enumerated above; it increases the tonicity of the sphincters and rectal muscles; by a reflex action on the nerves of the bladder, it causes this viscus to contract and empty itself, and, by a like stimulation of the sympathetic plexus, influences diuresis. Its antipyretic action is also evidenced by a reduction in temperature. Time and space forbid my entering upon a discussion of the treatment of the various complications presented by the gastrointestinal tract in this disease.

DISCUSSION.

Dr. H. B. Favill, Chicago—The question of the real value of different methods of treatment of typhoid fever is a very embarrassing one, because it takes such a vast amount of clinical data before we can arrive at conclusions which are really valuable. One point of importance is the varying relative gravity, or severity, of the clinical course in typhoid fever. This will not only lead to differences in results, but also leads to false conclusions as to the therapeutic observations. Referring directly to his own experience, he had observed a very great difference between the typhoid fever of 1898, and the same disease of preceding years. Is it that the type of typhoid fever is different? It is true that our therapeutic methods have improved, but he was also of the opinion that the type of typhoid fever has been decidedly mitigated, within the last eight or ten years. He was quite of the essayist's opinion that the therapeutic methods, of this country particularly, record a distinct advance in the treatment of typhoid fever, and he referred particularly to the use of the modified Brand method, which he uses in his own practice. The modern methods of treatment consist in gastro-intestinal disinfection and the modified Brand bath. He was unable to decide whether the amelioration is due to the improvement in gastro-intestinal hygiene or to the introduction of the Brand bath, but he was led to believe that it is the bath, rather than the antiseptic treatment. In his hospital practice he uses guaiacol instead of salol, as he found it less irritating. He could see no difference between the clinical effects of the two agents. He had found that it was most efficient if given when the stomach was comparatively empty, or not engaged in digestion. He approved of colonic flushing and had found that patients retained the normal salt solution when they could not retain the simple water injections.

Dr. T. B. Greenley, Meadow Lawn, Ky.—When he began practice in 1845 and up to 1875 he had never seen a case of autumn typhoid; it was always a winter or spring disease. Lately, he had begun to meet with cases of autumn typhoid, and recalled seeing six cases in one house. It was in the fall of 1876, that he had made a report of seventeen cases to the State Medical Association, in which he noted several points of difference between the disease and what he had seen previously. All of the seventeen cases recovered. In these cases he had not seen the preliminary nervous state lasting about a week, and the marked delirium, that he had been accustomed to see in former years. There was also less diarrhea. Also the pulse is frequently slower than in the winter and spring disease. He had never lost a case where the bowels were constipated throughout the disease. He also noticed a less amount of eruption than formerly. He therefore thought that the type had changed.

Dr. Thomas F. Reilly, New York City—In cases where constipation is marked he had found much benefit from small doses of strychnia frequently repeated. He inquired of the essayist if he had observed any ill effect upon the kidneys from salol, and secondly, whether he had noticed any lessening of the number of relapses under that treatment.

Dr. Warren G. Hill, Milwaukee—The important subject of feeding typhoid patients should be more carefully considered. In outlining the medical treatment we usually indicate what shall be given and how often, but in directions for feeding we may indicate what is to be given, and perhaps how often, but the quantity is less clearly defined. He had seen a most careful physician overfeed a patient with a most restricted diet, the patient being fed every two hours, and he got a large quantity at each time. His own opinion was that two hours was a little too short an interval; he thought that babies, even, often do better with an interval between feedings of three or four hours. Perhaps it would be better in typhoid fever to lengthen the interval and give less food. In fact, he was so careful upon this point that his patients were in the habit of saying to him that his treatment of typhoid fever was solitary confinement and starvation. He had kept patients for a week with very little food by the stomach; he used inunctions of cod-liver oil, allowing only a spoonful or two of koumyss by the mouth. In fact, this is his ordinary routine treatment when there is much disturbance in the alimentary tract. The advantage of hydrotherapy in his mind is that the patients take up a large quantity of water by absorption into the system; at the same time they have the stimulating effect of the cold, provided that there is sufficient vitality to produce stimulation, otherwise there would be depression. But in the latter group of cases we can resort to daily colonic flushing, in addition to bathing the surface with the sponge. The colonic irrigation must be conducted very carefully, because we all know from post-mortem examinations that the colon is often so distended that the muscular coat is almost entirely absent.

Dr. Frank Woodbury, New York City—Sterilization of the food and drink is an important part of the treatment, as well as the administration, in frequently repeated small doses, of intestinal antiseptics in order to prevent reinfection. Typhoid being largely a water-borne disease, it is important that the water used for drinking by the patient, or cooking for him, should be filtered and boiled before using, and that no ice should be given to him unless known to be from a pure source.

Dr. W. W. Tompkins, Charleston—In 1882 a company built a railroad in West Virginia and had 500 men employed, who lived in a camp. After living in one place until the camp became infected they would move off to a new place. Typhoid broke out in camp and, acting upon the advice of an old practitioner, he bathed all the patients. He extemporized a tub out of an old canoe. There were fifteen cases in the camp at this time. Every time the temperature went up to 102 F. they were soused in this bath; it did not matter whether they had pneumonia or other complication, or none at all, they all got the baths. In three months he treated 27 cases and all got well. It might be considered harsh treatment now, but the facilities were few and the only other treatment they got was whisky. Where cases had diarrhea or constipation, they were treated just the same. In many of his cases constipation appears early in the disease. His plan was to give small doses of castor-oil in milk and clear out the intestines so as to avoid the danger of ulceration, from irritation of contents of the tube. If the fecal masses are in the lower part of the colon we can reach them by flushing. This subject has been so frequently discussed at the state meetings and by the public press that it is well known and our patients generally know what to expect and what ought to be done in treating a case of typhoid fever. As regards the diet, there can be no question that milk is the best as a rule, but in some cases it does not agree with the patient and something else must be substituted. In some cases albumin water answers the purpose, in others meat juice. It has been suggested that small doses of calomel are useful during the first week, but his experience had been that the physician is not usually called in until as late as the second week. He inquired of the essayist if he would give calomel in such cases.

DR. J. M. ANDERS, in closing, referred to the statement made that there had been a change of type in the disease during the last decade or two, and said that he was of the same opinion; that the disease had become more mild in type. And yet we still see cases of severe type, and these are taken into consideration in the discussion in his paper. One speaker had expressed himself as being unable to decide whether the improvement was due to hydrotherapy in conjunction with diet and other remedies in modern treatment. His own opinion was that it was due chiefly to hydrotherapy. In cases in which this can not be carried out, the other measures do have special usefulness, and especially a careful dietary. The question had been asked if salol produces any ill effects? He could say that he had never seen a case in which the urine became smoky, although in a few cases it had assumed a pink hue, which generally passed away on diminishing the dose. He had never seen it do any harm. He had not noticed any beneficial effects from salol upon the tendency to relapse. He did not believe that it obviates a tendency to relapse to any appreciable extent. He had not found it to reduce the tendency to other complications, but reliable statistics are wanting on this point. With regard to feeding the patient, he thought it best to be as liberal as possible, however, without at any time exceeding the digestive capacity of the patient, as shown by an examination of the stools. If the stools show undigested material he reduces the food or lengthens the interval. He thought that the stools are not examined sufficiently often by the profession. In some cases it is necessary to examine them microscopically as well as macroscopically. They often show curds and scraps of food still undigested. In this case we may substitute some other form of nourishment. The good effects of the bath are most evident upon the nerve-centers, and the symptoms which proceed from the disturbed organic functions. The reduction of temperature is important, but it is secondary to the effect upon the nervous system of the cold bath. Where hemorrhage from the ulcerated patches occurs the only indication is absolute rest, both local and general. He felt certain, both from his personal experience and from published statistics, that the cold bath has increased the tendency to hemorrhage from the bowels, caused by the necessary disturbance of the patient. The question having been asked if calomel should be given to patients coming under observation late, he would explain that he did not mean that calomel was inadmissible in the later stage, but that the most good was obtained from its use in the first week. At the end of the second week he would not consider it contraindicated unless the patient were very weak, in which case he would prefer to use something less depressing in its effects.

THE INFLUENCE OF OVERCROWDING ON THE PREVALENCE OF TUBERCULOSIS.—That tuberculosis is more prevalent and more destructive where there is overcrowding and necessarily unhygienic conditions is shown by the fact that in Glasgow the death-rate per 100,000 of the population from diseases of the lungs, including tuberculosis, was in one-roomed or two-roomed houses, 985; in three-roomed or four-roomed houses, 689, and in five-roomed houses and upward, 328.

THE UNBROKEN SKIN AS AN ABSORBING MEDIUM.*

THOMAS F. REILLY, M.S., M.D.
MEMBER OF THE NEW YORK STATE MEDICAL ASSOCIATION.
NEW YORK CITY.

In a communication of this kind, consisting, as it largely does, of a review of the works of many observers, much condensation is necessary and many details must be omitted. In reviewing the literature of this subject from the beginning of the century, one is forcibly impressed by the ebb and flow in the popularity of the external application of medicinal agents for their constitutional effects.

Early in the century this method was much in vogue. After 1860, under the inspiration of the experimental physiologists it was relegated to the rear, and for almost a quarter of a century, with the exception of treatises on the use of mercurial inunction in syphilis, there was little written on the subject. Within the past decade the pendulum, largely influenced by the French school of clinicians, has begun to swing to the opposite extreme. The experimental physiologists demonstrated that the lack of homogeneity existing between the various layers of the skin would prevent the entrance of extraneous substances. That theoretic conclusion at first thought seems unanswerable. The crypts of the sebaceous glands, however, are lined with a different kind of epithelium, an epithelium similar in many respects to that of mucous surfaces, and allows the transmission of foreign substances quite as well as if they are brought in contact with it. Another fact demonstrated by later observers, notably Guinard and Linnossier, is that many of the agents that produce therapeutic results by means of cutaneous application are converted into a gaseous state before absorption takes place. The free passage of most gases, particularly oxygen and carbon dioxid, through the skin has been a well-known fact for many years, but it is of quite recent date that the practical application of this principle has obtained. The observers before mentioned clearly proved that when some of the medicinal agents, to be mentioned hereafter, were applied to the skin, without an occlusive dressing, only an infinitesimal amount could be recovered from the urine. If, however, an occlusive dressing of oiled silk and cloth were applied over the substance a very considerable amount could be recovered. This simple principle will account for many of the failures to secure therapeutic results in the past.

Another forward step was taken when Waller and others discovered that many substances, which of themselves could not produce constitutional effects when applied to the skin, might be absorbed if they were dissolved in a volatile substance, such as ether, chloroform or alcohol, which itself is absorbed in a volatile state. The absorption of aqueous solutions of non-volatile bodies by the normal skin is practically impossible. Bartholow's fanciful theory that since the blood is alkaline, acid fluids ought to pass through the skin by a process of osmosis, has not been verified. Non-volatile powders placed on the skin are likewise not absorbed. Guinard made 250 experiments with various substances of this class and never succeeded in finding any trace thereof in the excretions. Whatever absorption takes place in the mineral baths is due to the transmission of the gases evolved and to the presence of exposed mucous surfaces, such as the rectum, vagina, etc.

---

* Presented to the Section on Materia Medica, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

The discussion of absorption by cataphoresis, which is closely related to the subject under consideration, would unduly lengthen this paper, and must be deferred. Vanni and Giuicardi believe that substances dissolved in organic liquids are more readily absorbed, and have reported the successful use of morphin and sodium salicylate when dissolved in human saliva. Their results have been disputed by Destot and others. Much had been expected from the inunctions of metals in the colloidal state, but with the exception of silver there has been little encouragement in that direction.

Fats.—A certain proportion of most fats is absorbed. It is taken up almost entirely through the sebaceous glands. Medicinal agents contained in the fatty bases are likewise taken up in varying quantities. To obtain any decided absorption, vigorous and prolonged friction is necessary in order that the substance may come in contact with the glandular epithelium. Fürbinger believes that mercury when used in the form of an inunction, is volatilized in the crypts of the glands, and finds its way into the circulation in the same manner as other gases. The same reasoning might apply to the iodid of potassium. There is, however, sufficient evidence to prove that constitutional effects may be produced by the inunction of non-volatile bodies.

INUNCTION BASES.

Petrolatum.—The value of petrolatum for this purpose is practicaly nil. This is due to its tendency to gum over the mouths of the glands.

Vasogen.—The trade name for an oxygenated vaselin is one of the latest products of Teutonic genius. It has been highly recommended as an inunction base, but its real value has not yet been determined. Many similar preparations that were lauded to the skies have come and gone. Lard and the various animal and vegetable oils have a moderate penetrating power.

Oleic Acid.—Judging from the literature, it might be supposed that oleic acid had lost much of the popularity that it enjoyed some years ago. It is in extensive use, however, and by many is considered to be the most efficient base for this purpose that we possess. Incompetent pharmacy is responsible for many of the failures attendant on its use.

Adeps Lanæ.—To Oscar Liebreich belongs the credit of calling attention to the old wool-fat, or œsypus, and of first demonstrating its exceptional properties as an inunction basis. He showed that wool-fat is a mixture of cholesterin and the fatty acids, which latter, however, must be removed to render the product thoroughly suitable to the skin. He also proved that the fat of the human skin and its sebaceous glands, as well as the vernix caseosa of infants, is essentially identical with wool-fat, being composed of cholesterin and iso-cholesterin. It is derived from the wool-fat of the sheep and has been popularized under the name of lanolin. This is claimed to be a purified adeps lanæ, to which water may be added. As watery solutions of certain medicinal agents do not mix well with other fats, this is of a decided advantage, both for incorporation and absorption.

Aubert, as a result of a most thorough and painstaking investigation of the subject, believes that for simple topical application pure lanolin is inferior to other bases, but where friction is employed it is the best basis that we possess. He advises that it be mixed with castor-oil and applied with friction for from five to ten minutes.

Plasters.—It might be expected that there would be a considerable amount of absorption following the application of plasters on account of the length of time they are in a position. Anders believes that the constitutional effects of belladonna may be obtained in this way in children, and that the effect is more continued than when the drug is administered by mouth. The literature on this branch of the subject is very meager.

CONDITIONS FAVORING ABSORPTION.

Bourget found that, after 40 years of age, absorption diminished. It is much more marked in the young. The skin of women is more permeable than that of men. Those of light complexion have more permeable skin than the dark; fat people, more than those with a dry harsh skin.

It had been noticed for a long time that salivation was much more easily produced when mercurial inunction was made over hairy parts, as the pubis, than in other localities. Aubert, after carefully studying this phenomenon, decided that it was due to the increased number of glands and hair follicles present wherein the mercury was more rapidly absorbed. Thus, he produced the effects of pilocarpin by mixing it with lard and then rubbing it into the hairy regions, whereas the effect obtained when applied in other localities was very slight. Those parts of the body covered by thin skin and abundantly supplied with lymphatics, as the axillary and inguinal regions are, must be superior to the more dense structures. Pavolsky advises that the skin be washed with ether to remove oil, filth, etc., before the application of the medicament. Certainly, the parts should be cleansed with soap and warm water beforehand.

INDIVIDUAL APPLICATIONS OF MEDICINES.

A critical review of the literature has elicited the fact that the following agents may be absorbed through the skin and produce constitutional effects.

Mercury.—The first account of the use of mercurial ointment for inunction appears in 1494. Probably the employment of this and other substances by this method is much older. That mercury will produce its effects when administered in this way is generally conceded. The suggestion that the mercury be applied to the sole of the foot and thus rubbed in by the constant movement of the foot in walking is both ingenious and practical, and might be employed in the case of other agents equally as well. By some authorities mercurial soap is preferred to the soap for inunction. It is said to consume less time in its application. Vogel and Bermartzik say that if 1 per cent. sublimate lanolin ointment be rubbed into the skin of the palm of the hand a metallic taste may often be detected in the mouth within a few minutes.

Iodin.—This, either in the form of the tincture or as the iodid, is certainly absorbed. It has been found in the urine by many observers. The iodid has usually been employed in the form of an ointment. Iodid of potassium is decomposed at the body temperature, and in order to secure the full effect an occlusive dressing is necessary. The ordinary tincture when applied should likewise be covered with an occlusive dressing or, what in a measure amounts to the same thing, petrolatum. Elsberg thinks the ordinary tincture too weak and advises a 20 per cent. solution in ether and alcohol. An interesting feature in the absorption of iodid when applied to the skin, is that the amount eliminated by the kidneys and detectable in the urine does not increase gradually but by sucessive leaps.

Europhen and Iodoform.—Dr. F. Flick asserts that both iodoform and europhen in a solution of cod-liver oil are absorbed by the skin. He has employed these mixtures for nine years and is positive that it produces the constitutional effects of the drugs. Zera J. Lusk has successfully employed an iodoform poultice in seven cases of tuberculous peritonitis. Linnosier has found that considerable amounts of the iodoform may be recovered from the urine following such applications.

Salicylic Acid.—The absorption of salicylic acid is fairly rapid. This may be accounted for by reason of its keratolytic action, and because it is volatile at the body temperature. Reed found that if it be dissolved in alcohol and chloroform, and covered by an impermeable dressing he could detect it in the urine within twenty minutes. Sigalas and Combermalle go even further and assert that when it is rubbed into the skin and covered by a suitable dressing it can be detected in the urine in five minutes. According to Cullen, these authors have succeeded in effecting the absorption of sodium salicylate in the same manner. As might be expected, methyl salicylate, occurring alone or in combination, as in the oil of gaultheria or oil of birch, is readily taken up. Vidal has demonstrated that for this purpose the artificial oil of gaultheria is preferable to the natural oil, in that it contains more of the salicylate and less irritant substances and it does not blister. The ordinary synthetic oil of the shops answers quite as well as the preparations so extensively advertised. This method, either alone or in combination with internal medication, is employed in the treatment of acute articular rheumatism in most of the hospitals of Paris and New York, and gives great satisfaction. I have employed it in the last twelve cases of articular rheumatism and can testify to its efficacy. From one to two teaspoonfuls of the artificial oil are poured on a piece of flannel. Each of the affected joints is encircled by such a dressing and covered with oiled silk, and over this a thick flannel bandage is applied. This procedure is repeated from two to four times daily. Others employ it in ointment form. Lately this plan of treatment has been recommended in the management of acute chorea by Professor Bozzolo, of Turin. It has been suggested that the absence of salicylism, following such application, is due to the slowness of absorption, thus not permitting any great accumulation of the agent in the blood at any one time.

Silver.—The inunction of metallic silver, in the form of unguentum Credé has been successfully employed in many forms of general sepsis. Gustav Shriner reports a number of cases of cerebrospinal meningitis successfully treated by this agent. Credé states that two-thirds of the ointment penetrates the skin, and he has proved this by microscopic sections. Forty-five grains are sufficient in mild cases, and friction should be employed from twenty to thirty minutes. Roswell Park, Marx, Jones, Osborne and others have had excellent results from its use. The literature is quite extensive.

Quinin.—Inglis, Moncorvo and others assert positively that quinin produces its effects when applied locally in the form of an ointment. This method is especially useful in children. Lanolin or oleic acid are the bases usually employed. This means of administering quinin is very popular in and about New Orleans. From personal experience I believe it to be efficacious.

Phenacetin.—A few writers have employed phenacetin in the form of ointment with seeming good results.

Turpentin.—If confined, turpentin certainly does produce its good effects, and this is sometimes painfully evident if the kidneys are diseased.

Guaiacol.—Guaiacol has been used locally with undoubted success in the treatment of the pyrexia of typhoid fever, and tuberculosis. It must be volatilized, and therefore an impermeable dressing is essential.

Creosote.—Fitzgerald, of the English medical service in India, reports twenty-six cases in which creosote in olive-oil was absorbed and lowered the temperature in malarial fever. Gilbert employed it for this purpose in the pyrexia of phthisis with seeming success.

Croton-oil.—Croton-oil, if rubbed on the skin in sufficient quantity, will produce its constitutional effects. A large part of this absorption is due, however, to its preliminary destructive effect on the epidermis.

Ichthyol.—Inasmuch as very little is known of the constitutional effects of ichthyol, we can not say positively that it is absorbed. Lately it has been employed for its constitutional effects in smallpox and measles. It is said to have rapidly reduced the temperature to normal.

Pilocarpin.—This causes a profuse sweating in the parts where it is applied and effects the general condition but slightly. N. S. Davis, Jr., of Chicago, is satisfied that this method of producing diaphoresis is of distinct value in uremia. In a case of my own there was an undoubted increase in the amount of perspiration at first, but it did not continue. The case finally recovered. The usual strength employed was 5 cg. of pilocarpin in adeps lanæ. Effects are not to be expected until three hours have elapsed.

Digitalis.—This is usually employed in the form of a poultice made of the leaves. How it can act unless there be a volatile principle present is not known, but certain it is that many competent observers believe that it produces the effects of the drug on the kidney when administered in this manner.

Belladonna.—There have been many cases of belladonna poisoning reported where large amounts of this agent were employed in this manner. Certainly, the effects of the drug may be obtained by inunction. An ointment of the extract is the preparation most employed. The experiments of Aubert, however, demonstrated that the action of the atropin is largely exerted on the local glands that are covered by the inunction. After the application of an onion or garlic poultice, suitably covered, the odor can be detected in the breath. This volatile principle occasionally appears to exert a favorable influence in the bronchitis of children.

Carbolic Acid.—The effects of carbolic acid are sometimes apparent when large quantities are used as a dressing on the unbroken skin, especially if there be an occlusive dressing applied. This must be due to the transmission of the gas that is evolved and might be avoided by the use of a light permeable dressing.

A large percentage of the practitioners of medicine in this country, I believe are convinced that inunctions of cod-liver oil have some specific value in certain so-called scrofulous conditions, although it would be difficult to prove this in a scientific manner. Drs. Randolph, and A. E. Russel, of Philadelphia, say that they have seen the oil in the feces when rubbed into the skin.

DOSAGE.

It is customary to give the dosage as two or three times that of the same drug when administered by mouth. We can safely quadruple the dosage in most cases, as the absorption is so slow that accumulation of the medicine in the system in sufficient quantity to be dangerous is hardly possible in that strength.

A medicinal agent to be absorbed by the unbroken skin, must either become volatile during its application, or be incorporated in a fatty base and applied with friction. Occlusion is an absolute requirement in the case of volatile substances. Most of the absorption occurs in the crypts of the sebaceous glands. The effect is much slower, about one-fourth as intense, and longer continued than when the same agent is administered by mouth. A large number of medicinal agents, which when given by mouth are intolerable to many patients, may be administered in this way with scarcely any unpleasant effects.

IDIOSYNCRASY AS TO MERCURY.

A CASE OF ERYTHEMA MERCURIALE.*

ALBERT BERNHEIM, M.D.
PHILADELPHIA.

In the history of many a great man, we are told that he had a peculiar aversion to some special thing, be this a cat or a rooster, or a flower or some perfume. In some cases of reconvalescence, we find special aversion to smoke, even in persons who have been addicted to smoking. Such aversions may be temporary or constant. If the aversion is temporary, we should call it a disposition in consequence of some disturbance in individuality; but if it is constant we may call it a peculiar constitution of individuality, in consequence of which particular agents operate on the individual in a manner different from their ordinary mode of action on persons in general; briefly, we may call it an idiosyncrasy. Even animals are reported to have idiosyncrasies, thus the horse to the camel.

Idiosyncrasies are not uncommon; they occur in regard to various agents. Perhaps the most frequent ones are those in relation to some foods, such as strawberries, and certain fish. Others are connected with drugs and medicine. A well-known German professor of surgery could not stand iodoform; some can not use carbolic acid; others can not take antipyrin without becoming subjected to an eruption of blisters on many parts of the body.

In the literature on the use of mercury, we do not find so frequent an idiosyncrasy to this drug, and extraordinary effects of it, that it would not be worth while to mention such effects when they do occur, especially when such symptoms incline to simulate phenomena of syphilis, erysipelas and scarlet fever.

If we look over the literature of the 19th century, we do not meet many cases of untoward effects of mercury compared with its numberless uses.

One of the first who wrote about the unexpected effects of mercury was G. Alley,[1] of Dublin, who published, in 1804, in a large treatise, several cases of a peculiar eruption arising from mercury. About the same time, McMullen,[2] in Edinburgh, described similar cases; Spens[3] followed, in 1805, with a description of three cases of erythema mercuriale. They considered the correctness of the name—eczema or erythema. Others again called it erysipelas, and as late as 1887 Dr Kreidmann[4] discarded the bacteriological origin of erysipelas in favor of medicinal causes, such as mercury.

In 1811, A. Ramsay,[5] and in 1812 J. Frank[6] and J. Nicholson[7] related cases of mercurial erythema. H. Becker[8] published a treatise, "De Erysepelate Mercuriali," in 1817; B. Kahleis[9] spoke of mercurial rose in 1823; in 1845 Rambant[10] called attention to purpura hemorrhagica caused by mercury; and Larmande[11] wrote about a hydrargyro-atrophic erythema in 1880.

S. Snell[12] described in 1882 a peculiar idiosyncrasy as to mercury; Alexander[13] related in 1884 a case of acute universal mercurial eczema; a year later Descroizilles[14] wrote on mercurial eczema. P. Gaucherand[15] wrote in 1886 about scarlatiniform skin eruptions caused by internal administration of mercury; Blanc[16] and Kreidmann, in the following year, make observations on mercurial scarlatiniform erythema.

In more recent years, Robinson[17] speaks of an individual who was suffering from two attacks of erythema, one after the other; the first after mercurial inunction, and the second after internal use of calomel. G. Lewin[18] exhibits a case of toxic exanthema caused by quicksilver; and Fordyce[19] mentions a case of desquamative exanthema that had been diagnosed as scarlatina.

Mrs. V. G., 50 years of age, mother of seven children, felt intense itching on her hands and arms in the morning of January 20; the following day she had a rash on her throat, flexor sides of her arms, palms of the hands and flexor sides of her legs; the eruption was the most marked in the hollows of her knees, flexor sides of wrist and elbows. An extensive redness was visible all over the skin of these said parts; the rash consisted of dark-red, small elevations over the level of the skin and felt, to the touching hand, like velvet; the elevations corresponded to the hair-follicles; on January 22 the skin was edematous and hardened like in erysipelas; fever did not exist; urine was abundant, and of a water-like color; no albumin; no sugar. Diagnosis was uncertain. I remembered then that patient had told me of eruptions she had had in 1869, 1875 and 1882, and that she had an idiosyncrasy to the use of any kind of ointment. The eruption appeared to me as a symptom of poisoning.

---

* Presented to the Section on Materia Medica, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

The very intelligent patient gave me the following history of the previous cases of rash: In October, 1869, she consulted a physician for removal of a red spot of the size of a silver dollar, on her neck. The spot was a reminder of a vesicatory put there when as a little child she was believed to suffer from meningitis. The physician prescribed for this spot a grayish ointment. After a single inunction she got an itching rash over her throat, chest, abdomen, flexor sides of arms and legs, with subsequent furunculosis on several parts of the body, particularly the arm-pits. In 1873 the patient married; in October, 1875, after a pregnancy, the hair began to fall out; she used a hair pomade; after its use for the first time she got an eruption on her throat, hands, neck and back of the head. In May, 1882, after another pregnancy, she was suffering from constipation. The same physician who had treated her in 1869 prescribed a powder of grayish color, and greasy, shining appearance. A few hours after taking the first powder a rash all over the body—throat, chest, flexor sides of arms and legs, hands—occurred, followed by furunculosis again. The new attack of eruption seemed to her to resemble the previous ones.

I learned that the patient had taken on the evening of January 19, two pills, and on January 20, three pills, as a laxative, and on closer investigation I found out that the pills were blue-mass pills of 2 grains each; the diagnosis then was easy; it was a case of effects from mercury.

In the previous times, as well as in the new attack, the skin scaled off in large lamellæ, like in scarlet fever, except that the desquamative process was to a thicker extent. The teeth were greatly affected in the attack of 1882, not so in this eruption. Mercurial diarrhea did not occur, there was rather an inclination to constipation.

The urine was examined for the presence of mercury, according to Almen. I used for the purpose a very fine copper wire, such as taken for induction coils of faradic instruments. The examination was positive.

Patient comes from a healthy family; none of her sisters or brothers is known to be subjected to the same idiosyncrasy, except that father and one sister in younger years could not eat strawberries without getting a rash; later on they were not affected any by eating the berries. The children of the patient are not known to suffer from the same disposition, for one or the other has taken the same blue-mass pill or calomel.

The treatment consisted of administration of two tablespoonfuls of castor-oil and magnesium sulphate; of hot baths, diaphoresis, drinking of egg albumin stirred in boiled and cooled water, of large quantities of hot milk and hot water. The itching was first treated with inunction of vaselin and dusting of borated talcum powder, but with not a great success; it stopped promptly on administering potassium iodid, 8 grains in 150 grains of water three times a day; a second examination of urine did not exhibit mercury any longer. A struma that had existed for several years subsided simultaneously with the administration of potassium iodid.

A NEW OBJECTIVE TEST FOR MASTOIDITIS.

WITH REPORT OF CASE.

ALBERT H. ANDREWS, M.D.
CHICAGO.

The use of the tuning-fork and the stethoscope to determine the comparative density of the two mastoids furnishes a valuable aid, and so far as I am aware, a new method in the diagnosis of mastoid complications. The test is made by placing a stethoscope with a small bell over the tip of the mastoid, and placing the handle of a vibrating tuning-fork over the antrum. It is found that when the mastoid is filled with pus or graunlations or when it is dense from obliteration of the air-cells the sound waves are transmitted to the ears of the examiner more distinctly than when the stethoscope and tuning-fork are placed in the same relative position over the opposite or normal mastoid. Care must be used, in making the test, not to stretch the skin between the stethoscope and the handle of the tuning-fork, for then the vibrations are heard better than when the skin is not stretched, even though the distance be less.

The lower border of the middle fossa can be very accurately located by the same method. While the bell of the stethoscope is upon the mastoid the vibrating fork is moved downward over the squama and as soon as the upper border of the mastoid is reached the sound becomes much louder. The line indicating the change from cranial cavity to mastoid is usually well defined. When this line is reached a move of an eighth of an inch makes a marked difference in the sound of the fork. The position of the lateral sinus in relation to the mastoid can be determined in the same manner, though with less accuracy.

Since beginning the use of this test I have examined forty cases without mastoid symptoms and have found no perceptible difference in the resonance of the two sides; while in the examination of four cases of undoubted mastoid disease the affected mastoid transmitted the sound waves to the stethoscope with greater force than did the mastoid of the opposite side. One of the mastoid cases was recently operated on and the following description gives the chief points:

Mrs. S., colored, aged 40, gave a history of suppuration of the left ear for fifteen years, with occasional attacks of acute pain in the ear and side of the head. For three weeks before coming to the clinic she had suffered continuously from a dull pain in the ear and mastoid, which sometimes extended over the side of the head and as far forward as the eye. Examination showed that the membrana tensa had disappeared. The ossicles could not be seen. A cholesteatomatous mass occupied the attic and upper portion of the cavity of the middle ear. When portions of this mass were removed the surface beneath was covered with granulations. The temperature during her attendance at the clinic varied from normal to 101 F. Deep pressure over the mastoid caused pain. In testing the comparative resonance of the two mastoids I found that when the bell of the stethoscope was placed on the tip of the mastoid with the handle of the tuning-fork over the antrum the resonance of the left side was much greater than that of the right. The time which I could hear the fork on the affected side was thirty seconds, and on the normal side was sixteen seconds.

A mastoid operation was done December 20. The usual post-auricular incision was made, and the mastoid cortex found to be of ordinary density. The air-cells were small and filled with granulations. Hemorrhage from the mastoid wound was unusually profuse. The cavity was cleared of diseased tissue, the posterior wall of the auditory canal and the outer wall of the attic chiseled away, and the granulations and cholesteatoma carefully removed from the attic. The facial nerve was found exposed just above the oval window, and sponging of the cavity caused twitching of the left eye-lid and side of the face. A slit was made throughout the entire length of the posterior part of the membranous auditory canal; and the mastoid cavity, the middle ear and the auditory canal were lightly packed, through the meatus, with iodoform gauze. The posterior incision was completely closed with sutures.

The only thing of special interest in the case is the condition of the mastoid in relation to the test with the stethoscope and tuning-fork. The fork I have used in these tests is a C 512, so constructed that it should be heard by the normal ear about thirty-five seconds. The stethoscope has a metal bell five-eighths of an inch in diameter.

100 State Street.

OCULAR MANIFESTATIONS OF DIABETES MELLITUS.*

L. A. W. ALLEMAN, A.M., M.D.

BROOKLYN.

To the practitioner of general medicine, the eye symptoms of diabetes have only a general interest, save in their diagnostic and prognostic significance. I shall, therefore, in this discussion, avoid a detailed consideration of the ocular findings, from the standpoint of one interested in diseases of the eye, and briefly examine the relation of the more important symptoms to the primary disease. It is unnecessary to caution you against that unwarranted faith in ophthalmoscopic findings which one sometimes finds among the laity. Many patients feel perfectly assured of their physical soundness when told that no evidence of disease can be found in the eye, but I am not so sure that it is unnecessary to warn you against a too broad skepticism. It is true that no systemic disorder writes its name in large type on the background of the eye. Syphilis does not have the sole prerogative of producing iritis, nor diabetes of causing hemorrhagic retinitis, but it is true that in certain general diseases ocular symptoms are found with sufficient frequency, and a clinical picture of sufficient definiteness is often enough obtainable to make us reasonably certain, from the eye symptoms alone, of the underlying disorder.

Further, there is information to be obtained by the ophthalmoscope, of the condition of the circulation, of the changes in the vessel walls, as well as of disease of the nerve, which is in many instances of the very highest importance and which I believe is obtainable in no other way. This is a broad field, one as yet but little cultivated; we have studied the findings discovered in more advanced conditions with much care, but it is the early conditions which we should investigate. When the student with the ophthalmoscope shall work with the student of general medicine and when their tentative findings shall have been shifted by the pathologist; when such results have been patiently collected and digested, I am convinced that the opportunity for inspection of living tissues, which the eye alone affords, will take rank as one of the most important of diagnostic methods.

While ocular lesions may be present in all forms of diabetes, they are more frequently found in the chronic cases without marked general disturbances. It is, possibly, the supposed need of change in glasses which brings the majority of these cases under our observation, for refractive changes are incidental to many of the eye symptoms of diabetes. A few cases are on record in which hypermetropia has developed as a result of diabetes, and in some instances[1] it has varied with the amount of sugar in the urine. This peculiar phenomenon is due, according to Landolt, to a change in the index of refraction of the vitreous.

The development or the increase of a pre-existing myopia is a much more common occurrence. This is frequently associated with changes in the lens, but is also seen when no evidence of cataract is present. These refractive changes are often early symptoms and are important in suggesting the possibility of some serious general disease. Langford[2] formulates the proposition that, "The onset of myopia in patients of 50 years of age or upward without discoverable abnormality in the lenses should always excite suspicion of diabetes;" and it is well on general principles to question any too frequent necessity for change of glass.

Paralyses of the extraocular muscles occur in mild as well as severe cases of diabetes, and may be present in patients unaware of any serious constitutional disorder. These paralyses may be transient and improve and recur with the progress of the general condition. This variability is particularly observed in the lesions occurring early in the disease; the later paralyses are much more permanent. Any of the extraocular muscles may be involved. The cause of these paralytic conditions is believed to be nuclear or peripheral hemorrhages, or peripheral neuritis. Paralysis of accommodation is probably the most frequent of the ocular complications of diabetes. It was first observed by von Graefe, and as in most other instances his opinion has been confirmed by later observers. Paralysis, or more properly paresis, of accommodation, for the paralysis is often incomplete, is in many cases among the very earliest symptoms of diabetes.

---

*Read at the Sixteenth Annual Meeting of the Fifth District Branch of the New York State Medical Association, held in Brooklyn, May 22, 1900.

[1] Landolt: The Refraction and Accommodation of the Eye, p. 417.

[2] Norris and Oliver: System, Vol. iv, p. 667.

An incomplete paralysis is often unrecognized by the patient as such. They only observe increased difficulty in reading, which is relieved by a stronger glass, and belong to the class, to which I have previously referred, who first learn of the diabetic condition when examined for glasses. The relation of diabetes to cataract is a question which has occasioned no little discussion; some authors claim that there is a true diabetic cataract while others contend that lenticular changes are no more common among diabetics than in patients of the same age suffering from some other debilitating disease. Among patients past middle life I am inclined to believe that the influence of diabetes on cataract formation is through the general nutritive disturbances and arterial degeneration by which it is accompanied; but in the young there seems to be some direct causal relation, and the unexplained development of juvenile cataract requires exclusion of diabetes, as a possible cause, by a careful physical examination.

The most interesting, if not the most frequent, ocular symptoms of diabetes are found in the retina. It has long been known that pathologic changes are frequently found in the retina of diabetics, but owing to the similarity of these lesions to those found in other diseases attended with vascular degeneration and particularly to those of renal retinitis, many observers have denied that a true diabetic type of retinal disease could be distinguished. Hirschberg,[3] who has given much careful study to this subject, is convinced that there is a distinctive diabetic retinitis, presenting in most cases either a degenerative or a hemorrhagic type, and he points out the features which distinguish it from the other forms of retinal disease. He admits that his contention is not universally accepted, and explains this fact as largely due to the confusion of other observers, who have not taken into account the frequency with which renal lesions develop in diabetics. When the two diseases coexist we may have a mixed type of retinal disease, or a diabetic retinitis may take on a renal character when the disease of the kidney is developed in the diabetic, or a patient suffering from diabetes and renal disease may not develop a diabetic but an albuminuric retinitis. Again, there are periods in the progress of the case, during which either the sugar or albumin may disappear from the urine of a patient, who, nevertheless, is suffering from both diseases. In such an event the ophthalmoscopic findings would not be sustained by a single urinary examination made at this time. Making due allowance for these facts there is no difficulty in recognizing a diabetic retinitis which can always be confirmed by physical examination. These contentions of Hirschberg seem to be well grounded and I am inclined to accept them. The typical diabetic and renal cases are surely distinct enough, but I have never chanced to see the mixed type. Retinitis is often a late symptom of diabetes and develops after the general symptoms have been long present and are well marked; but this is by no means always the case and the diagnosis of diabetes may be first made when patients are examined for glasses or consult us for some blurring of vision, flickering before the eyes or other ocular symptoms.

Retinal hemorrhages, with or without other retinal changes, are always suggestive of diabetes, particularly the small punctate hemorrhages. They are often associated with conjunctival hemorrhages; they are absorbed and recur. They are sometimes very numerous, but frequently cause little disturbance of vision. Retinal changes are always present in a case of diabetes which has existed for more than ten or twelve years, and are usually considered terminal symptoms of the disease; this is not however entirely unquestioned. I believe, while always an unfavorable symptom, retinal complications do not by any means indicate an immediate termination of the disease. Hirschberg makes a distinction between the degenerative and hemorrhagic forms, and considers the cases with profuse hemorrhages far more serious. In my own experience I have known diabetics with recurrent retinal hemorrhages to live many years in comparative comfort, and I can not view the diabetic lesions with the same alarm as those of renal disease.

There is another ocular symptom which is not uncommon and which has occasioned much discussion. This is the central scotoma.

Diabetics sometimes present a clinical picture which is almost identical with that found in the toxic amblyopias. So similar are the conditions that they have been called tobacco amblyopias in diabetes, and the frequent occurrence of these symptoms was supposed be due to the lessened resistance to the tobacco poison among diabetic subjects. As the symptoms are found in patients who use neither tobacco nor alcohol, and who are suffering from no known toxic influence, we are forced to conclude that the poison must be in some way due to the disease. Recent studies of toxic amblyopias have largely changed our ideas of the pathology of these conditions, and the peripheral neuron, which has of late been upsetting most of the established theories of the pathology of the nervous system, seems to be the offending member in this condition as well. The altered state of the blood and the profound nutritive disturbances seem to furnish us with sufficient explanation of these symptoms, which are probably similar pathologically to the other toxic amblyopias.

There are many other diseases of the eye which are caused or modified by diabetes. Iritis of a severe plastic type is met with and is always dreaded after operation on diabetic subjects.

Keratitis, which is pre-eminently an attendant of faulty nutrition, is a natural consequence of the disease, and when occurring is often a serious condition. Optic-nerve atrophy and amblyopia, without discoverable lesions, are sometimes seen. The latter symptom is probably similar to uremic amblyopia in origin, and is sometimes a forerunner of diabetic coma.

The eye symptoms are on the whole of far more diagnostic than prognostic significance. They are nearly all seen as both early and late symptoms, and are indications rather of the present nutritive condition than of the extent of the irreparable damage to the organs. The most valuable prognostic indications are to be discovered by the ophthalmoscope in the retina, and particularly in the condition of the retinal vessels.

A patient may rally from a profound toxemia, but "he is as old as his arteries."

Remote Prognosis of Serofibrinous Pleurisy.—A French author reports in the current issue of *Arch. de Méd. Navale*, all the cases of serofibrinous pleurisy observed in the navy between 1877 and 1899, a total of 352 cases; 320 patients were discharged cured, and 32 died in the course of the disease. He finds that 131 have since died, and that in 118 of these death was due to tubercular infection. The remainder, 189, are still living. He therefore concludes that in a third of all the cases serofibrinius pleurisy, apparently primary, is in reality of tubercular origin. He found the left side more frequently affected than the right.

SOME REMARKS ON THE PLANTAR REFLEX, WITH ESPECIAL REFERENCE TO THE BABINSKI PHENOMENON.[*]

J. T. ESKRIDGE, M.D.
Alienist and Neurologist to St. Luke's Hospital; Consulting Alienist and Neurologist to Arapahoe County Hospital, and Neurologist to the U. P., D. & R. G., and C. & S. Railroads.
DENVER, COLO.

(Concluded from page 183.)

Early in this paper I mentioned the fact that in seven nurses on duty in the Arapahoe County Hospital I found the plantar reflex absent in 5; present in both feet in 1, and absent in one foot and present in the other in 1. These results seemed so remarkable that I decided to examine the plantar reflexes of the nurses in St. Luke's and Arapahoe County Hospitals. I found 54 vigorous and strong nurses, both in the hospitals and among graduates doing private nursing outside, who were willing to have their plantar reflexes examined. The results were as follows:

The plantar reflex was absent in 63 per cent., and present and normal in 11, or about 20.3 per cent. It was irregular, such as present in one foot and absent in the other, spreading of toes, flexion or extension of one or more of the small toes and flexion of the great toe and extension of small toe in 9, or 16.7 per cent.

There must be some steadily acting cause in nurses to give rise to the absence of plantar reflex in such a large percentage of healthy individuals. My first theory was that it was because the nurses were on their feet so many hours, but on re-examining the nurses in the early morning whom I had examined after a day's work, I found no changes practically in the plantar reflex. I then examined my own plantar reflex and found it present and normal both night and morning. I was forced to abandon this theory. In looking over my records of 2550 old cases and finding that the plantar reflex disappeared in nearly all cases of extreme exhaustion, especially just before death, in tumor and abscess of the brain and in the profound comatose stage preceding death, I felt that the frequent absence of the plantar reflex in nurses was caused by exhaustion from overwork. I again re-examined my own plantar reflex when I felt extremely exhausted from trying to work a few hours after suffering from an attack of cholera morbus. In this instance I found my plantar reflex absent. Another time, after getting exhausted the reflex was present in one foot, absent in the other.

It would be interesting to examine the plantar reflex in smelter men after a hard day's work. In looking over Drs. Walton and Paul's[4] paper two paragraphs (pp. 310, 311) attracted my attention in this connection. They state:

> In 100 cases, apparently healthy, taken from the gymnasium and other places outside of a hospital, they found the reflex as follows: In 75 per cent. normal plantar reflex, no movement in 10 per cent., and in 15 per cent. flexion on one side and absent reflex on the other.
>
> In 100 patients taken at random from a general hospital, especially selecting those who were not suffering from any disease that would interfere with the plantar reflex the averages were as follows: Flexion of toes—generally the outer—87 per cent., absent reflex in 9 per cent.. flexion on one side and absent movement on the other. 4 per cent.

The hospital patients, who were doing practically nothing, showed a higher number with normal plantar reflex, 87 per cent., than the 100 who resided without the hospital.

In the case of the nurses that I examined, I noted how long each had been in training. I found the plantar reflex absent nearly as frequently in nurses who had been in the school a few weeks or months as in those who had graduated or been in training nearly all of their required time. But here again I found that most of the nurses had come from positions that had required them to be on their feet a great deal.

If observations show that those who have absent plantar reflex for prolonged periods are more subject to certain diseases than those who have a normal reflex, our duty as physicians will be plain.

Examination of 7 healthy children: Extension of all the toes when the children were asleep in 3; unsatisfactory examination in 4, principally on account of the constant movement of the feet while I was trying to examine them. Sometimes the toes would apparently flex on irritating the plantar surface, but on pursuing the examination they would extend and again flex. The ages of the children varied from five days to three months.

Plantar reflex in 40 surgical cases: Normal reflex was present in 30, 75 per cent.; absent in 10, 25 per cent. In 4 of the cases marked flexion of the toe movements were very irregular. In one there was flexion of all the small toes in one foot and absent reflex in the other; in the second there was abduction of the little toe in one foot and quick extension of the great toe in the other; in the third, separation, without flexion or extension, of all the small toes, the great toe remaining quiet; in the fourth, nearly the same phenomenon was observed as took place in the third.

Typhoid, 17 cases: Normal reflex was present in 12, 70.5 per cent.; absent reflex in 3, 17.5 per cent.; flexion in one foot and absent in the other, 2, 12 per cent.

Consumption, 13 cases: Plantar reflex was present in 11, 84.7 per cent.; absent in 2, 15.3 per cent.

In 50 medical cases: Plantar reflex was present in 46, 92 per cent.; absent in 4, 8 per cent.

In the 240 cases just reported, in which there was no evidence of disease of the pyramidal tract, the Babinski phenomenon was not found in one. In one case the right great toe extended but the movement was quick and jerky, all the other toes remaining quiet.

NERVOUS DISEASES—100 CASES.

Dorsal and cervical myelitis: 7 cases with extensor plantar reflex, 100 per cent.

Dorsolumbar myelitis: 7 cases, absent reflex in all, 100 per cent.

Complete destruction of cord: One cervical, 2 dorsal and 4 lumbosacral, 7 cases; plantar reflex was absent in all, 100 per cent.

Idiopathic muscular atrophy, 2 cases: Plantar reflex was absent in both, 100 per cent.

Hemiplegia, 10 cases: Plantar flexion was present in 9 cases 90 per cent; absent in 1, 10 per cent.

Epilepsy. 4 cases (using bromid): Plantar reflex was absent in all, 100 per cent.

Locomotor ataxia, 6 cases: Plantar reflex was present in 2, 33.3 per cent.; absent in 4, 66.7 per cent.

Plantar reflex was absent in 1 case swollen feet from heart disease. 100 per cent.

Swollen feet from kidney disease, 5 cases: Plantar reflex in all was absent. 100 per cent.

Bilateral thrombosis, 2 cases: Flexion plantar reflex was present in 100 per cent.

---

[*] Read in abstract at the Seventh Annual Meeting of the Academy of Railway Surgeons held in St. Paul, Minn., Sept. 5-6, 1900.

Delirium tremens, 2 cases: Plantar flexion was present in 1, and absent in 1, 50 per cent. each.

Feigned aphasia, 1 case; Plantar reflex was R. absent, and L. Present.

Dementia, 9 cases: Flexion plantar reflex was present in 3, 33.3 per cent.; absent in 6, 66.7 per cent.; in one plantar reflex flexion was present on one side and all reflex absent on the other.

Melancholia, 12 cases: Plantar reflex was present and normal in 2, 16.7 per cent.; absent in 10, 83.3 per cent.

Imbecility, 1 case: Plantar reflex was absent, 100 per cent.

Idiocy, 2 cases: Extension reflex existed, 100 per cent.

Extreme degree of hydrocephalus, 1 case: Plantar flexion reflex was present, 100 per cent.

Paretic dementia: 4 cases: In 2 plantar réflex was absent; in 2 present on one side and absent on the other; absent, 75 per cent., present 25 per cent.

Hip disease, 3 cases: Flexion plantar reflex was in all, 100 per cent.

Spinal rigidity, 1 case: Flexion plantar reflex was present, 100 per cent.

The following 450 cases of nervous and mental diseases have been studied with especial reference to the Babinski phenomenon, in my office, in consultation practice and in attendance on private cases in St. Luke's Hospital, during the past eighteen months.

Tumor of the brain, 8 cases: Of these 3 tumors in pyramidal region, extension plantar reflex was present in all of affected leg, 100 per cent.; flexion plantar reflex was on opposite side in 2 cases, 66.7 per cent.; absent reflex existed on opposite side in 1, 33.3 per cent. Of 5 tumors outside pyramidal region, flexion was present, 60 per cent.; absent in 1 case, 20 per cent.; flexion was present on one side, absent on the other, 20 per cent.

These tumors are divided into two classes one which invades the pyramidal or motor region, and the other which does not affect this region, and the percentage is calculated in the one instance on the number of tumors affecting the pyramidal tract, which is 3, and in the other on the number without the pyramidal tract, which in this instance is 5.

Abscess of brain, 1 case: Plantar flexion was present, 100 per cent.

Meningitis, 30 cases: Flexion was present on both sides after coma in 5, 16.7 per cent.; extension on both sides in 5, 16.3 per cent.; flexion present on one side and absent on the other 3.3 per cent.; absent in 19, 63.3 per cent.

Epilepsy, 21 cases: Plantar reflex in 18, 86 per cent.; irregular in 3, 14 per cent.

Syphilis of the brain or cord, 20 cases: Flexion was present in 15, 75 per cent.; absent in 3, 15 per cent.; irregular in 2, 10 per cent.

Old hemiplegia, 30 cases: Extension reflex on affected side in 25 cases, 83.3 per cent.; extension reflex on opposite side in 3, 10 per cent.; reflex absent on both sides in 5 or in 16.7 per cent. In the latter there were trophic changes in the paralyzed limb.

Bilateral thrombosis, 2 cases: Extensor bilateral reflex was in both, 100 per cent.

Posterior spinal sclerosis, 20 cases: Flexion plantar reflex was just perceptible, irregular or delayed in 14, 70 per cent.; absent in one foot and present in the other (flexor) in 2 cases, 10 per cent.; absent in both feet in 4 cases, 20 per cent.

Multiple neuritis, recent and old, 6 cases: Flexion was present in 2 cases, 33.3 per cent.; absent in 3, 50 per cent.; present in one foot and absent in other, 1 case, 16.7 per cent.

Anterior poliomyelitis (old and recent), 106 cases: Flexion was present in 6, 60 per cent.; present in one foot in 3 and absent in the other, 30 per cent.; absent reflex in 1, 10 per cent.

Pressure neuritis affecting sciatic nerve: 8 cases: Normal plantar reflex was present in all; 100 per cent.

Pressure neuritis of nerves of leg, 10 cases: Normal plantar reflex present in 8, 80 per cent.; absent in 2, 20 per cent.

Myelitis, 8 cases: Extensor plantar reflex was present in 50 per cent.; 4 dorsolumbar was absent, 50 per cent.

Complete transverse lesion of cord, 1 case: Plantar reflex absent, 100 per cent.

Spinal caries, 10 cases: with pressure on cord above, lumbar region 4 cases, extension plantar reflex in all, 40 per cent.; spinal caries without cord lesion, flexion plantar reflex in 4, 40 per cent.; spinal caries with cord lesion in lumbar region absent reflex, 20 per cent.

Paralysis agitans, 3 cases: Sluggish flexion existed in all, 100 per cent.

Hysteria, 10 cases: Flexion plantar reflex was in 5, 50 per cent.; absent plantar reflex in 4, 40 per cent.; flexion plantar reflex in one foot, absent in the other, 10 per cent.

Neurasthenia, 25 cases: Reflex was normal, but often almost imperceptible plantar flexion, including cases of increased plantar reflex, 23 cases, 92 per cent.; absent plantar reflex in 1 case, 4 per cent.; absent in one foot and present in the other in 1 case, 4 per cent.

Nervousness, to which name neurasthenia or hysteria can not be properly applied, 15 cases: Flexion was present in 14, 93.3 per cent.; absent in one foot and present in the other, 7 per cent.

Traumatism to head, with no gross lesions of the brain substance so far as I was able to detect, 12 cases: Flexion plantar reflex was present before shock had passed away in 10 cases, 83.3 per cent.; absent plantar reflex in 2, 16.7 per cent.; after shock is over flexion plantar reflex was found in all, 100 perment.

Traumatism to spine, with no gross lesion, 8 cases: Four cases with profound shock, plantar reflex was absent, 50 per cent.; 4 cases with minor shock plantar reflex was present, 50 per cent.

Dementia, 30 cases: Plantar flexion reflex was present in 11, 36.7 per cent.; absent in 15, 50 per cent.; extension plantar reflex in 4, 13.3 per cent.

Paretic dementia, 15 cases: Flexion plantar reflex was found in 14, 93.3 per cent.; absent in 1, 9.7 per cent.

Mania, 10 cases: Flexion plantar reflex was present in all, 100 per cent.

Melancholia, 22 cases: Plantar reflex was absent in 16, 72.7 per cent.; present, but irregular, in 6 cases, 27.3 per cent.

Paranoia, 15 cases: Flexion plantar reflex was present in all, 100 per cent.

Feigning, 4 cases: Flexion plantar reflex was in 3, 75 per cent.; plantar flexion was present in one foot and absent in the other in 1 case, 25 per cent.

Stuporous melancholia, 4 cases: Absent plantar reflex was in all, 100 per cent.

Melancholia attonita, 1 case: Normal plantar reflex was present, 100 per cent.

Weakmindedness, 10 cases: Flexion plantar reflex was present in all, 100 per cent.

Imbecility, 12 cases: Flexion plantar reflex was present in 9 cases, 75 per cent.; absent or irregular in 3 cases, 25 per cent.

Idiocy, 13 cases: Flexion plantar reflex was present in 6, 46.5 per cent.; absent in 4 cases, 30.5 per cent.; irregular in 3 cases, 23 per cent.

Deaf-mutes, 6 cases: Flexion plantar reflex was present in all, 100 per cent.

From a careful study of the literature of the plantar reflex, together with my personal investigations, I have to admit that the plantar reflex as found in children is unsatisfactory; and that the plantar reflex may be variable—irregular—absent in both feet, or absent in one foot and present in the other, more frequently than has commonly been supposed, especially by those who have not devoted considerable time to investigating this reflex in apparently healthy subjects.

It does seem to me that the claim of Collier, that extensor plantar reflex is present in total transverse myelitis, needs confirmation. Babinski did not obtain it. I have never found it in cases in which I could say that the cord was absolutely destroyed in any portion of its extent. It is not always easy to say when the cord is completely destroyed.

Langdon found the plantar reflex absent in tetanus. Collier found extensor plantar reflex present in a case of tetanus. This discrepancy between two good observers is easy to reconcile. In Langdon's case, the disease ran a rapid course and the patient died at the end of the third day, if I mistake not. Of course, the patient must have been greatly exhausted. I have found in all diseases with profound exhaustion that the plantar reflex disappears before death. In Collier's case the disease was milder, ran a slow course and the patient finally recovered. The lateral columns of the cord are probably in an irritated condition in tetanus until the stage of exhaustion is reached. The extensor plantar reflex is what we are prepared to expect in strychnin intoxication, or in fatal poisoning from this drug. This test may be of value in a diagnosis between strychnin poisoning and a hysterical attack simulating the drug poisoning.

I make this as a suggestion. May not a hysterical subject in a paroxysm so excite the pyramidal tract to such a degree as to render it possible for one to obtain a temporary or an irregular form of the Babinski phenomenon? In hysteria one occasionally obtains a quick extension of the great toe. It is soon exhausted and totally unlike the deliberate extension of the great toe found in the majority of persons suffering from disease of the pyramidal tract.

Giudiciandrea claims to have found extension of the great toe in hysteria and in normal subjects. Schüler obtained extension of the great toe in 8 per cent. of men and in 4 per cent. of women whom he examined. Cohn states that he found extension of the great toe in 20 per cent. of his subjects. He also found extension plantar reflex on the affected side of a case of hysterical paralysis.

When I began to investigate the plantar reflex with especial reference to the Babinski phenomenon, I found extensor reflex in a number in whom I was confident there was no lesion of the pyramidal tract, and I began to be skeptical as to the value of the Babinski phenomenon. I soon learned to note the difference between the pseudo-Babinski phenomenon and the phenomenon described by Babinski in 1898. On re-examining these nervous and hysterical subjects, I did not find a genuine case of the Babinski phenomenon in which there were not other evidences of disease of the pyramidal tract.

You may ask me: Does the presence of flexion plantar reflex enable one to exclude disease in the pyramidal tract? I do not think investigation has gone far enough to enable any one to give a positive answer to this query. Personally, I do not remember having met with a case of disease of the pyramidal tract in which flexion plantar reflex was present on the affected side.

Diagnosis.—That the Babinski phenomenon is valueless in diagnosis, the most skeptical deny. In fact, Martin Cohn, who is often quoted as doubting the value of the reflex under discussion, is in some respects one of its firmest supporters. His conclusions are: "In the majority of all persons an irritation of the sole of the foot is followed by flexion of the toes. In lesions of the lateral tract of the spinal cord of an organic character, an extension reflex is to be observed." He then adds: "In no way, however, can this phenomenon be regarded as a certain pathognomonic symptom for the recognition of such a disease."[8] How few symptoms have we that are positively pathognomonic of certain lesions of any organ? It is only on account of the number of irregular and unexpected results obtained by Cohn that most investigators of the Babinski phenomenon have come to look on Cohn as a skeptic.

A case presenting most of the symptoms of posterior spinal sclerosis would not be diagnosticated as a clean-cut case of this disease if the extensor plantar reflex were present. Such a reflex would probably show that the lateral columns were also diseased.

A case simulating strychnin poisoning, or tetanus, without great depression and absent extensor plantar reflex, would, in all probability, justify the diagnosis of hysteria.

Prognosis.—The Babinski phenomenon may have uses in prognosis. In the discussion on the conjoint papers, one by Walton and Paul, and the other by Fraenkel and Collins, presented to the last meeting of the American Neurological Association, Dr. Spiller said that "he believed in recent cases of hemiplegia in which the knee-jerk was found absent several days or weeks after the hemiplegia had developed and the Babinski reflex was present, prognosis was bad."[2] He admitted that he had observed only two cases that justified such a conclusion.

Prevention.—If it is found by subsequent investigators that persons following certain vocations attended with considerable exhaustion, the majority of these—as in the cases of the nurses reported by me in this paper—have absent plantar reflex and subsequently suffer from disease affecting the legs or feet, or the nervous tone more frequently than persons with normal plantar reflex, a timely investigation of the reflex may save many continuing too long in positions attended with great physical exhaustion. In fact it may be possible to judge by a study of the plantar reflex in many—especially in those whose plantar reflex is present when they are not exhausted—the degree of exhaustion from which they are suffering.

It is possible that much valuable information may be obtained by a further study of the plantar reflex, especially in the line of prevention, as well as in those of diagnosis and prognosis.

CONCLUSIONS.

1. The Babinski phenomenon is an extremely valuable sign in diagnosis, and probably in prognosis and prevention.
2. It is not a pathognomonic sign of organic disease of the lateral tract.
3. We shall learn by subsequent observations that several poisons or conditions so irritate the lateral tract as to cause a pseudo-Babinski phenomenon, or an apparently genuine one temporary in character.
4. Greater care should be used by the investigator, and the carefully studied cases should be much more numerous.

THE BACTERIOLOGY OF BRONCHITIS.

Bronchitis is a common affection, both as an independent disease and as a secondary and complicating process. That bronchitis generally is an infective disease is probably not to be doubted, but considerable vagueness certainly exists as to the special organism or organisms that sustain the most important relationship to the disease. The first question to be determined in studying the bacteriology of bronchitis is whether the lower air-passages—trachea, bronchi and pulmonary alveoli—normally contain pathogenic bacteria. The majority of observers hold that the lower air-passages are normally sterile. The bacteria present in the air are probably all withdrawn as the inspired air passes through the nose and the pharynx. That bacteria are removed from the air during respiration is shown by the fact that expired air is generally sterile; and it is thought that the bactericidal power of the nasal mucosa is an important factor in cleansing the air. Direct bacteriological examination of the healthy air-passages in man and in animals has shown them in many instances sterile.

Jundell,[1] for instance, who, by means of specially constructed instruments, examined the tracheæ of 43 persons during life, found the respiratory tract below the glottis either quite sterile or else containing scanty and transitory bacteria. Assuming that the bronchi are normally sterile, it is found that in bronchitis the bronchial secretion contains a variety of bacteria which different writers consider as the causal agents. Different methods of examination naturally yield different results in the case of a secretion that is as exposed to accidental contaminations as the bronchial. Acute bronchitis in adults can be examined post-mortem only rarely. And in children, in whom acute bronchitis is so frequently present, the conditions found post-mortem may not be the same as during life, because the bronchi are in direct communication with the mouth, which harbors a rich bacterial flora; contamination by post-mortem invasion of the tissues of the body is also possible.

Everything considered, however, W. T. Ritchie[2] concludes that a careful examination of the contents of the smaller bronchi soon after death would yield reliable information as to the bacteria of bronchitis in children. A large number of cases were examined by means of a reliable technic and it was found that in practically every case of acute bronchitis there were numerous pathogenic bacteria in the bronchi, the list given including streptococci, staphylococci, colon bacilli, influenza and diphtheria bacilli, B. pyocyaneus, and encapsulated bacilli. The diplococci of pneumonia and streptococci were the most common; in the majority of the cases a mixed infection was present. The bacillus of influenza appears to cause bronchitis not infrequently, even apart from epidemic influenza. Ritchie's investigations go to prove that acute bronchitis is an infective disease not due to any single specific micro-organism. He did not extend his bacteriological study to the organs of the body in general. A complete investigation of this kind would have given us important information in regard to the relationship of the bacteria of bronchitis and general infection, terminal or otherwise.

OBSTRUCTIVE BILIARY CIRRHOSIS.

Cirrhosis of the liver is an exceedingly interesting process, which, in spite of the great amount of work devoted to make clear its exact etiology, still remains imperfectly understood. One reason for the comparative mystery that surrounds the exact pathogenesis of many forms of hepatic cirrhosis is the failure to discover reliable methods whereby experimental cirrhosis may be produced with certainty. Reduced largely to the study of post-mortem material, the investigators have exhausted histological and bacteriological methods without fully solving the intricate problems involved. A number of more or less distinct forms of cirrhosis of the liver have gradually been established and in the case of at least one form, namely, obstructive biliary cirrhosis, the exact etiology is now fairly well understood, largely because in this case it was possible to make suitable experiments upon animals.

William W. Ford[1] presents a full review of the observations on this form of cirrhosis. Since J. Wickham Legg, in 1874, and J. M. Charcot, in 1876, established obstructive biliary cirrhosis as a separate disease, something over 200 cases have been collected from the literature, 184 by Mangelsdorff in 1882 and 21 by Ford for the period 1882-1900. Ford adds 3 new cases from the Royal Victoria Hospital in Montreal. It has been shown by a number of experimenters that complete obstruction to the outflow of bile in animals leads to an interlobular cirrhosis, caused, as Ford concludes, by the damming back of the bile, and not necessarily secondary to a cholangitis of the smaller bile-channels. In man complete occlusion of the bile-ducts leads to a cirrhosis of the liver; here inflammation of the walls of the biliary channels is always present and this cholangitis is of etiological importance in causing the cirrhosis, being superadded to the effects of the damming up of the bile. Anatomically, obstructive biliary cirrhosis does not differ so much from Hanot's hypertrophic cirrhosis with jaundice, but the symptom-complex of obstructive cirrhosis differs wholly from that of Hanot's cirrhosis; hence the two forms are quite distinct. In obstructive biliary cirrhosis the course of the disease is acute, without intermission of symptoms, the jaundice being deep from the first; the liver, at first large, commonly contracts and there develop ascites, edema of the extremities and caput medusæ. In hypertrophic cirrhosis the course is chronic, the jaundice slight at first and then increasing, the liver rarely contracting.

---

[1] American Journal of the Medical Sciences, cxxi, 60-84.

The causes that lead to obstructive biliary cirrhosis may be congenital deficiency of the bile-ducts, gall-stones and the consequences thereof, carcinoma of the head of the pancreas, and the pressure of enlarged lymphatic glands at the hilus of the liver. The livers are greatly enlarged with a rough surface, the weight is increased, the cut surface showing greatly dilated biliary passages and areas of new connective tissue. As indicated, contraction occurs in the later stages with obstruction to the portal circulation. Hypertrophic cirrhosis with jaundice—Hanot's cirrhosis, biliary cirrhosis—shows a symmetrically enlarged and jaundiced liver, the common and hepatic ducts being pervious. The French school hold that Hanot's cirrhosis is caused primarily by infection, and it thus differs etiologically also from obstructive biliary cirrhosis.

DISINFECTION OF THE URINE FROM CASES OF TYPHOID FEVER.

Even before the discovery of the typhoid bacillus and the establishment of its etiologic relations, it was appreciated that the intestinal discharges constituted an important agency for the transmission of the hypothetic virus of the disease. As time went on and bacteriologic knowledge increased, it became recognized that typhoid fever is not exclusively a disease of the intestinal tract, i. e., that its lesions are not confined to these structures; and, further, that the intestine may even escape. Alert and industrious investigators soon showed that typhoid bacilli are eliminated with the urine in a considerable proportion of cases of typhoid fever, sometimes in enormous number and generally in pure culture. The micro-organisms do not, as a rule, appear in the urine until the second or third week of the disease, and when once present they may persist for long periods of time, even for years. The urine may exhibit little or no other alteration, and the presence or the absence of bacilli is thought to be without prognostic significance.

With the knowledge of these facts, it is obvious that the urine, not less than the intestinal discharges, may be an important factor in the transmission of typhoid fever, and both should, therefore, be equally subjected to disinfection as a prophylactic measure. Dr. N. B. Gwyn[1] has recently reported the results of an investigation into the comparative value of various disinfectants in rendering sterile urine containing typhoid bacilli. It was found that milk of lime, or slacked lime, while the cheapest disinfectant, is neither rapid nor certain in action, and in order to obtain results at all satisfactory one must use a solution so concentrated that on standing it will precipitate half of its actual volume of lime. Carbolic acid proved of value only in large amount, or in very strong solution. Mercuric chlorid, on the other hand, acted as a powerful and rapid disinfectant, only a small amount being required, and having the further advantage of being clean, odorless and easily applied. Formaldehyde was found to be a fairly efficient disinfecting agent, but its cost precluded its use in any but dilute solution. Chlorinated lime, prepared in saturated solution and using the supernatant fluid, proved itself a most reliable disinfectant, free chlorin being evolved on addition to the urine. The liquid chlorids—a mixture of zinc, aluminum and copper chlorid—was somewhat less active.

For disinfection of the urine in the bladder and the urinary system, urotropin, administered by the mouth, has been employed, with the results more or less satisfactory. Solutions of mercuric chlorid, 1 to 100,000 or 1 to 50,000, may be employed for irrigation of the bladder, and with some assurance that any bacilli in this viscus will be destroyed.

THE OPERATIVE TREATMENT OF SUBDURAL HEMORRHAGE.

The usual cause for hemorrhage into the brain is rupture of a diseased vessel, sometimes superinduced by increased blood-pressure. The condition, therefore, apart from the generally inaccessible situation of the extravasation, is one from the operative treatment of which not much is to be expected. Hemorrhage into the membranes of the brain, however, is more commonly of other etiology, and is correspondingly more amenable to surgical intervention. This condition is often due to traumatism, resulting in rupture of one of the venous sinuses of the dura mater internally, or of the middle meningeal artery, or of the veins of the cortical pia mater. Independently of traumatism, it may be due to rupture of aneurysms of the large arteries at the base or on the convexity of the brain, to the escape of blood from an intracerebral hemorrhage, to senility, chronic disease of the kidneys, heart or blood-vessels, hemorrhagic disease, such as purpura, scurvy, hemophilia, anemia, leukemia, hematoma in the insane—bleeding from a meningeal vein—internal hemorrhagic pachymeningitis, and activity in an overheated atmosphere. The symptoms are not always distinctive and the diagnosis is sometimes exceedingly difficult. When, however, it appears reasonably certain that an intracranial extravasation of blood has taken place in an accessible situation, operation will be clearly indicated. The number of cases in which this has been successfully undertaken is not large, although sufficiently so to justify its performance under suitable conditions.

An instance of this kind has recently been reported by Dr. J. Ramsay[1], of Launceston, Tasmania. The patient was a man, 54 years old, addicted to alcoholic excess, who had set out to bring home a newly purchased horse, and was found unconscious on the road, with the horse standing beside him. In the course of an hour or two consciousness partially returned and the man became greatly excited. When examined, some forty hours later, a small bruise of the scalp was found in the left occipital region, without evidence of injury to the skull. Occasional irregular movements and twitching appeared in the right wrist and hand, later also in the left, then likewise in the lower extremities, and finally on the left side of the face. A general convulsion now occurred, and was followed by several others, urine and feces being passed involuntarily. In the attacks the movements began on the left side of the face, extended to the upper and the lower extremity on the same side, and then became general, the right side of the face alone not being involved. In the intervals the right arm was rigid and the left flaccid. The urine contained albumin. Breathing became Cheyne-Stokes in character. The condition not yielding to bleeding and sedatives, trephining was undertaken. On exposure of the right motor area a large flat blood-clot was found on the surface of the brain just beneath the dura. This was removed and the wound closed. Two convulsions occurred subsequently, but none thereafter. Some mental and motor impairment remained, though gradually lessening in degree.

THE SALT CURE!

A Paris dispatch says all medical Paris is ringing with laughter over American physicians' enthusiasm in the salt cure. One physician is reported as saying that "these Christopher Columbuses of the medical profession on the other side of the Atlantic have disclosed one thing, that is, their ignorance and credulity." It might be said, on this side, that whoever is thus excited to laughter on the other side of the Atlantic displays equal ignorance and credulity in putting faith in yellow-journal reports that American physicians are enthusiastic over the salt cure.

DEATH OF QUEEN VICTORIA.

The death of Queen Victoria is an event that in many ways calls for notice even in a journal not devoted to general recording of political events. Her long and beneficent reign covered nearly the whole period in the past century in which the epoch-making advances in our science have been made. The Victorian era will go down in the history of medicine, as in that of literature and of science, as the brightest in our records. No ruler has had his or her name associated with so much that is of benefit to our race, or has, within the limitations of the position, more deserved it. In her personal character, which is of more importance in a monarch now than was formerly the case, she has left an example that it is hoped will be followed by her successors for all time. It is worthy of mention in this connection that the new king of England has done himself the honor of accepting an honorary membership in the medical profession. We trust that he may worthily wear it in his new responsibilities.

THE KANSAS LYNCHING.

The disgrace to Colorado in the brutal lynching of a negro by burning noticed in The Journal, last month, has been paralleled by a similar outrage in Kansas. These two occurrences indicate a psychological condition of the communities in which they occur, and in which, it is claimed, conviction for the crime is impossible; that is certainly worth consideration. Such relapses toward savagery would seem to warrant the views of some anthropologists as to the degeneration of the white race in America, but for the fact that in these, as in nearly all outrages on negroes in the northern states, the foreign-born element largely prevails. What they really indicate is that in certain classes of society civilization is only skin deep and in communities where the enforcement of the law is lax the underlying brutality will show itself. What Kansas and Colorado need is the thorough application of the law to lynchers, and until this is done they will remain disgraced. If conviction is impossible in Leavenworth, that city will have to bear its special dishonor which it thus insures.

REGULATION OF PRACTICE IN MICHIGAN.

The Michigan State Board of Registration has made its report to the governor and includes in it, among other like facts, that a number of persons were found practicing medicine under diplomas or certificates as pharmacists, dentists, etc. In one case where the practice had been carried on for years under the sanction of a dental diploma, the nature of the qualifications was explained to the holder, who remarked that it was "very funny; I paid for the other kind and supposed I had it." The members of the legislature can appreciate such facts as the above and realize that the state board is a protection to the welfare of the citizen. It is to be hoped that they will remember this when the quacks make their attack on the state board in the present session. The Michigan law is far from being an ideal measure, but the present state board is demonstrating what can be done even with such an imperfect medical-practice act. It is "the man behind the gun" that wins battles, and there are states with far better laws than that of Michigan that are worse protected against quacks.

ANTITOXIN.

The New York *Tribune* of January 13 publishes reports obtained from the respective health departments, and from inquiries of physicians, as to the effects of the use of antitoxin in diphtheria in various cities. In Baltimore the report of Dr. William Royal Stokes, city bacteriologist, gives a mortality with its use of less than 9 per cent., and of only 36 per cent. in the laryngeal form of the disease. In Chicago the reduction of the death-rate from diphtheria has been 50 per cent.; in Buffalo the mortality from the disease has been lowered over 60 per cent., and the results of the antitoxin treatment, as shown by the actual figures when they were compiled, astonished even the health officials themselves. In St. Louis the general consensus of opinion among physicians seems to be unanimously in favor of antitoxin, and in the city hospital where only the worst cases are found, it is the routine to give it in all cases of throat trouble before bacteriologic examination is made. In Paterson, Newark and Jersey City the same story was told. In Newark where statistics were reported they gave a decreased mortality of the disorder from 38 per cent. to 15.4 per cent., and in 1899, when, according to the percentage tables there should have been under the antitoxin treatment 445 deaths, there were actually only 124. In that city also figures are given of the death-rates of cases treated with and without antitoxin respectively, showing a nearly double ratio of the latter. All these statements, of course, only confirm the general testimony from the experience of the profession, but as long as there are still some posers as unbelievers in antitoxin it is well they should be placed on record. While as a rule attempts at publication of medical facts in lay journals are not to be commended, in a case like the one here noted the effects are likely to be salutary.

INCREASED MORTALITY FROM CARCINOMA.

The truth is not always pleasant, but however unpalatable, it is probably never so potential for evil as even sugar-coated error. Attention has been called by a number of observers to the fact that carcinoma is becoming increasingly prevalent, but the statement has not been acceptable and attempts have been made to cast doubt upon its accuracy. Nevertheless, the evidence would seem to suport the contention for such an increase. Thus, Thomas Oliver,[1] in discussing the question of the heredity of carcinoma, points out that statistics, both in England and in America, show that while the mortality-rate from tuberculosis is decreasing, that from carcinoma is notably on the increase. Thus, the mortality records of the Mutual Life Insurance Company, of New York, covering the period from 1843 till 1898 and dealing with 46,525 deaths include 882 due to carcinoma. The age-period in which the largest number of deaths from this cause occurs is from 55 to 60 years. In 1879 the percentage of deaths from carcinoma between the ages of 50 and 70 years was 4.23; in 1889, 6.22; in 1898, 7.59. According to the statistics of the Scottish Widows' Fund, the statistics of the deaths from carcinoma were, from 1815 till 1845, 0.93 per cent. of the whole number; from 1845 till 1852, 0.72; from 1852 till 1859, 2.87; from 1859 till 1867, 3; from 1867 till 1873, 4.56; from 1873 till 1880, 4.34; and from 1880 till 1887, 5.23. Twice as many females as males die from carcinoma, their mean age of death being 62.29 years, as against 60.43 years for males.

THE GOVERNOR OF CALIFORNIA ON THE PLAGUE.

The recent message of the Governor of California is interesting reading from a medical point of view. Although a layman, he poses as a medical expert and declares that from his own investigation he has proved that no plague has existed at any time in San Francisco, the opinions of the United States quarantine officers to the contrary notwithstanding. He suggests, moreover, that the only basis for the reports is the possible escape of plague germs from cultures and slides recklessly carried around in the pockets of "certain physicians and others," and that they innocently or otherwise inoculated a Chinese cadaver producing—post-mortem it appears—the enlarged glands and other macroscopic and microscopic signs of the disease. In view of the dangers he thus assumes in the above brilliant conception, he calls upon the legislature to make it a penal offense, with a maximum sentence of life imprisonment, for any one to have in possession or make from any case of plague any such cultures and slides without the written permission of the state board of health, fortified still further by executive approval. He would also make it a felony to publish any false reports of the existence of plague or to neglect to immediately inform the state board of health of any real or suspected case. The unlucky physician who suspects plague is thus between the devil and the deep sea; he is a felon if he falsely diagnoses, and also one if he fails to give utterance to his suspicions to a body that may for all he knows be conveniently organized to suppress such facts. The general tone of this part of the message, with its idiotic surmises and special pleading, indicates rather an attempt to prove a bad case than a genuine conviction that plague has not occurred. His muddle-headedness in regard to infection from "microscopic slides" and the inoculation of cadavers is funny, to say the least, and beautifully illustrates his pretensions to competency as an expert on the plague question in San Francisco. As a state paper, in this respect, the message is unique.

THE ACTION OF TUBERCULOUS TOXINS ON THE OFFSPRING OF THE TUBERCULOUS.

The question in regard to the heredity of tuberculosis is not as clearly understood as its importance demands. While the congenital transmission of bacilli from mother to offspring is demonstrated occasionally in rather special instances yet but comparatively few nowadays believe that the disease itself is commonly inherited. On the other hand there is a more general impression that the offspring of the tuberculous bring with them into the world a peculiar predisposition to tuberculosis, a lessened vital resistance, caused by the action of toxic substances on the organism. Experimental evidence in favor of this view is brought forward by Carriére[1]. Products of the distillation of cultures of tubercle bacilli on glycerinated peptone were injected into guinea-pigs, which were then bred; the fetuses were few, constitutionally feeble, often dying early without macroscopic evidences of disease. A small series of experiments seems to indicate also that the descendants of pigs injected with tuberculous poisons are more sensitive to tuberculosis, and most so when both father and mother were injected. These results are not directly applicable to man. Guinea-pigs are frail animals, the mere confinement of which may materially affect their vitality. But at the same time common experience teaches that healthy offspring presupposes a healthy and vigorous parentage, and tuberculosis when at all advanced is nearly always associated with wasting and enfeeblement. Whether the deleterious action of the tuberculous poisons, whatever their nature and mechanism may be, is so far-reaching as to threaten the existence of the human patient was a man, 54 years old, addicted to alcoholic excess, who had set out to bring home a newly purchased horse, and was found unconscious on the road, with the horse standing beside him. In the course of an hour or two consciousness partially returned and the man became greatly excited. When examined, some forty hours later, a small bruise of the scalp was found in the left occipital region, without evidence of injury to the skull. Occasional irregular movements and twitching appeared in the right wrist and hand, later also in the left, then likewise in the lower extremities, and finally on the left side of the face. THE CLUMPING OF BACILLI AND OF RED CORPUSCLES.

The essential importance of physico-chemical processes in biological phenomena is becoming more and more generally recognized. Indeed, it is along physico-chemical lines that we may look for satisfactory explanations of many phenomena in normal as well as pathological conditions, phenomena the existence of which is made clear, but not fully explained by studies of a morphological nature. And it is probably in this very field that the new century will witness the most far-reaching achievements in physiology and pathology. Sir Lauder Brunton's simple experiments[1] illustrating the clumping of bacteria and the formation of rouleaux by red blood-corpuscles show well what a flood of light may be thrown on such phenomena when they are approached from the standpoint of physics and chemistry. If lucifer matches are covered with hard soap and thrown into a flat trough containing water they float about indifferently, but if the water is acidulated the artificial bacteria are at once drawn together into clumps. If the fluid is made alkaline the clumps do not reform when broken up. On the addition of litmus to the water, the changes in color will indicate the changes in reaction. Artificial blood-corpuscles may be made out of sheet cork cut into discs and loaded on one side with bits of lead so as to float upright. As long ago as 1869 Norris showed that partially submerged artificial corpuscles are drawn together and form rouleaux. If totally submerged they remain separate. If dipped in petroleum they coalesce even under water. And Brunton shows typical rouleaux formation by treating cork corpuscles in the same way as he treated matches. These peculiar and interesting manifestations are probably connected with changes in the surface tension produced, and so Brunton suggests that the clumping of bacilli and the formation of rouleaux may be due to the liberation of some fatty substance by the action of carbonic acid. In the case of bacilli provided with flagella, clumping is more complex, because the flagella must be rendered motionless. Whatever the ultimate explanation, these experiments are certainly valuable also as a ready means of demonstrating to students how clumping may be produced.

Medical News.

CALIFORNIA.

Dr. J. J. Kinyoun, U. S. M.-H. Service, federal quarantine officer at San Francisco, is ill with appendicitis at his home on Angel Island.

Dr. Charles S. Stoddard has been appointed county physician and health officer for Santa Barbara and Montecito, at an annual salary of $1000.

The position of physician of Shasta County, which now pays $900 a year, is so much desired that three aspirants have filed petitions. One of these gentlemen generously offers, if elected, to do the work for $600 a year.

The charges of criminal neglect preferred against Dr. David Gochenauer, physician of San Deigo County, have been dismissed by the county board of supervisors, which at the same meeting re-elected Dr. Gochenauer county physician for the present year.

CONNECTICUT.

The Class of 1903, Yale Medical School, has adopted resolutions expressing its deep sympathy with the family of Arthur Ely, a member of the class, who recently died, and its sense of loss as a class by his death.

The new Maternity Hospital, erected at a cost of $38,000, on the grounds of the New Haven Hospital, under the supervision of a committee, of which Dr. William H. Carmalt was a member, was opened for inspection January 4.

Bristol has appointed four physicians as town physicians for the year, allowing each a compensation of $125 per annum.

The Board of Aldermen of Hartford, after much heated discussion, has decided to increase the salary of the city physician from $600 to $1000.

DELAWARE.

As a result of the January examination for license to practice, seven applicants have been granted certificates by the State Examining Board.

The Delaware State Hospital at Farnhurst, through its trustees, reports a deficit of $25,000 in the last two years, due to increase in the number of patients. It asks for an appropriation of $131,000 for the next two years.

Delaware Hospital, Wilmington, is a beneficiary by the will of the late Dr. W. W. Lesley, to the extent of $11,000, which is to be used to establish two free beds to be known as the William Wood Lesley and Sarah A. Lesley memorial beds.

The annual meeting of the trustees of the Delaware Hospital for the Insane was held in Wilmington, January 3, when contracts were awarded for food supplies for the institution. At this meeting Dr. Jean M. Wilson, pathologist to this hospital, sent in his resignation.

DISTRICT OF COLUMBIA.

Dr. George W. Foster, who has been connected with the Government Hospital for the Insane for about nine years, has resigned to accept the superintendency of the Second Hospital for the Insane at Bangor, Me.

The Columbian University Hospital, Washington, had its annual meeting January 3, at which the need of additional facilities was strongly urged. Dr. Albert F. A. King was elected president of the board, and Dr. E. A. de Schweinitz, secretary.

A bill has been introduced in the House of Representatives providing that the directors of Providence Hospital, Washington, be authorized to erect additional buildings and make such improvements for hospital purposes as they may deem proper on Square 764, now owned and occupied by that institution.

The attorney for the District, who was called on to decide whether or not an "electrical physician" required a license to practice, is of the opinion that unless the practice of an "electrical physician" is identical with the practice of massage, or the so-called Swedish movement cure, or unless the applicant intends to use ordinary domestic remedies without fee, gift, or consideration of any kind, he is required to obtain a license in accordance with the provisions of the act of Congress.

ILLINOIS.

Dr. George A. Zeller, Peoria, superintendent of the Hospital for Incurable Insane, who is now in the Medical Department of the Volunteer army in the Philippines, writes that he does not intend to return until the expiration of his term of service.

Because of the present system of appointing internes to Cook County Hospital, whereby none of the thirty-two internes at present is a native of Cook County, it is suggested that the positions be divided into three classes, one-third for the county, one-third for the state, and one-third for outsiders. The examinations would remain as at present; but it is thought that Cook County ought to retain the advantage of its institutions and not throw away all its benefits on outside physicians.

Efforts will be made by the Illinois Society for the Prevention of Consumption to induce the legislature to appropriate $200,000 for the establishment of a state sanitarium for the care of tuberculosis. Plans and estimates for the sanitarium have been completed, and Dr. John A. Robison, secretary of the society, has been instructed to submit them for the approval of the State Board of Health. The project is indorsed by Mayor Harrison, Health Commissioner Reynolds and the State Medical Society.

Chicago.

Judge Baker has remitted the fine noted last week, on Dr. Charles Eberlein, who left the court-room where he had been summoned as a witness.

The total mortality of Chicago for the week ended January 19 was 509, a mortality per annum of 16.61 per 1000. Of children under 1 year 111, and of adults over 60 years 107 died. Pneumonia caused 120 deaths; influenza, 18; consumption, 52, and violence, 26.

---

[1] Journal of Pathology and Bacteriology, 1900, vii, 53-54.

Among recent additions to the teaching force of Rush Medical College are D. G. Lingle, professor of experimental physiology; W. D. Zoethout, laboratory professor of neurology; F. C. Waite, assistant in anatomy, and C. H. Miller, technical assistant in the department of anatomy.

The State Board of Health has begun a crusade against the unlicensed practitioners, "healers," "magnetic physicians" and the like. "Dr." H. F. Coates, a "magnetic healer," was arrested January 13, while giving a "magnetic" treatment to 25 women. Edward Podatzekie was fined $100, January 14 for practicing medicine on a license issued to his wife.

On January 22, the isolation hospital contained 49 smallpox patients. Dr. Isaac W. Rawlings has been placed in charge of the hospital. The cases which are now being found come from a large area, extending all over the city. Three cases were taken to the hospital from Cook County Hospital and one from Michael Reese Hospital on January 21.

Except as to the smallpox situation the public health conditions have materially improved during the past week. Pneumonia is less virulent and the number of deaths from this cause is 25 per cent. less than for the preceding week. Unless the recent dust storms again kindle up the smoldering infection there is reason to believe that the worst of this outbreak is over.

The Chicago Clinical School has transferred to Dr. George Thomas Palmer the *Chicago Clinic*, which will be conducted by him beginning with the January number. It will hereafter be edited by Dr. Marcus P. Hatfield, and every effort will be made to make it a popular medical publication. This publication has been conducted for 13 years; it was started as the *Omaha Clinic*.

COMMISSIONS PROHIBITED.

Resolutions of great interest to the profession were presented at the January 23 meeting of the Chicago Medical Society, and after brief discussion, were referred to a committee consisting of Drs. James H. Stowell, Frank Billings, John B. Murphy, Louis L. McArthur and N. S. Davis, Jr. The resolutions were as follows:

> Whereas, It is commonly reported that some consultants and operators are in the habit of compounding fees; and,
>
> Whereas, The giving of commissions or a part of the fees by physicians or surgeons to any other person is detrimental to the good name of the profession and reduces the practice of medicine to the lowest commercial basis:
>
> 1. Because it is in effect the employment of an individual drummer for personal advertising;
> 2. Because it in effect promotes one's personal gains at the expense of other well-qualified physicians by an underhanded method of cutting fees, and,
> 3. Because it is in effect the *practicing* of a confidence game upon the patient; therefore, be it
>
> *Resolved*, That this course is considered dishonorable by this Society, and shall subject any member practicing it to expulsion.
>
> *Resolved*, That every member knowing or hearing of any member of the Society violating the spirit of this resolution is hereby earnestly requested to report the same to the committee on judiciary, in writing, with the fullest possible circumstantial statement, to the end that the facts or rumors may be thoroughly investigated for the benefit of the accused and for the benefit of the Society.
>
> *Resolved*, That it shall be the duty of the committee to employ every means in its power to ascertain the facts in the case; that it shall notify the accused of the charges; and shall give him every facility to explain the matter, and that it shall report its findings to this Society as soon as practicable.
>
> *Resolved*, That the willful violation of the spirit of these resolutions after this date shall be a good and sufficient cause for expulsion from this Society, and that upon the report of the committee upon any case, a three-fourths vote of the members present, by secret ballot, shall determine the action of the Society.
>
> *Resolved*, That the Secretary be instructed to send a copy of these resolutions to every member of the Society and to the various medical journals in this country.

INDIANA.

Dr. John R. Mauk, Cambridge City, one of the oldest and best-known physicians in eastern Indiana, is seriously ill.

Senator Charles Whitcomb will introduce bills at this session of the legislature establishing a state hospital for dipsomaniacs and other inebriates and one requiring county coroners to be physicians.

The State Board of Medical Registration is considering the proposition of slightly lowering the minimum requirements for the colleges that want their graduates to practice medicine in the state without examination.

During December, 2607 deaths were reported in Indiana, 308 of which were from consumption, 299 from pneumonia, 139 from typhoid fever and 20 from influenza. In Indianapolis and Evansville tuberculosis and pneumonia caused more than 70 per cent. of the total mortality.

IOWA.

Dr. Albert C. Phillips, Sioux City, being the lowest bidder for the position of physician of Woodbury county, has been awarded the contract, at $600 a year.

The Wapello County Medical Society has passed resolutions on the death of its late member, Dr. C. C. Powell, extending sympathy to his family and expressing its sense of bereavement at his death.

The physicians of Clinton have organized a Physicians' Protective Association with Dr. David T. Nicoll as president and Dr. Edward L. Martindale secretary. They agreed to furnish the secretary with names of candidates for the "blacklist," and condemned the plan of letting out the care of the county poor to the lowest bidder.

Iowa surgeons have entered on a crusade against the payment of commissions to country practitioners who send them cases for operation. They hope to secure the adoption of resolutions opposing this practice, when the State Medical Society meets in May, and to secure a bylaw making the penalty on any member of the society guilty of the practice, expulsion.

The State Board of Health has passed new rules providing that whenever any person shall be sent to any institution under the control of the board, except to either of the penitentiaries, from a locality where smallpox, diphtheria or scarlet fever is prevalent at the time of the reception of said person in the institution, there shall be furnished to the chief executive officer so receiving said person, a certificate that said person has not for seventeen days next preceding the time of sending been exposed to any such disease. And if, in such cases no certificate is furnished, said chief executive officer shall refuse to receive said person in said institution.

KANSAS.

Dr. W. B. Swan, Topeka, secretary of the State Board of Health, reports 262 cases of smallpox in the state, with two deaths.

Dr. Winifred S. Ferguson, Kansas City, has been fined $25 and costs for failure to report to the authorities a case of smallpox.

The physicians of the state are planning to secure legislation providing proportionate representation on the State Board of Health for the schools of medicine recognized by law. At present there are more than 2000 physicians of the regular school in the state and 317 of the homeopathic and eclectic schools; yet the State Board of Health consists of 3 regulars, 3 homeopaths, and 3 eclectics.

An unregistered physician of Anthony, who sued the estate of a deceased patient for $3050 for services rendered, had his claim disallowed by the probate judge, because he had no diploma from any medical school, and was not a member of any medical society. Under the laws of the state he is not recognized as a physician, and is therefore not entitled to collect any amount for services rendered.

MARYLAND.

Dr. R. P. Winterode, a graduate of the Baltimore Medical College, has been appointed pathologist at the Maryland Hospital for the Insane, Catonsville, to succeed Dr. Cornelius Deweese, recently resigned to accept a similar position at the Government Hospital, Washington, D. C.

The directors of the United Charities Hospital, Cambridge, Dorchester county, elected the following medical staff for the next two years: Drs. B. W. Goldsborough, chief of staff; Drs. John Mace and Guy Steele, local staff; Dr. Thomas S. Cullin, gynecologist; Dr. Nathan R. Porter, surgeon; Dr. Herbert Harlan, diseases of eye and ear; Drs. William Osler and Howard A. Kelly, consultants.

The State Board of Health, at its annual meeting, January 10, elected the following officers: Dr. William H. Welch, president; Dr. William B. D. Penniman, chemist, and Dr. W. Royal Stokes, bacteriologist. Dr. Johns Fulton, the secretary, submitted his annual report. There are 31 cases of smallpox in the state outside of Baltimore, viz., 6 in Allegheny county, 24 in Prince George's county, and 1 in Montgomery county. All these patients are in quarantine, and suspected persons are under observation, and Dr. Fulton says no alarm need be felt.

Baltimore.

Dr. Aaron Friedenwald has been elected president of the McCulloh Street Synagogue.

When an emergency call for vaccin physicians was made, January 6, 23 out of 24 physicians responded, and the twenty-fourth was prevented by illness.

A bill to pension the widow of Dr. Jesse W. Lazear, who died in Cuba, Sept. 25, 1900, while investigating yellow fever has been introduced in congress by Representative James W. Denny, of this city.

Dr. Charles W. Chancellor will memorialize the legislature of West Virginia to renew his lease of Berkeley Springs, which expired in 1900. He agrees to expend $50,000 in improvements on the springs. There will be determined opposition by other would-be lessees.

Dr. Anna Giering, of this city, was arrested at the instigation of Mr. Anthony Comstock. agent of the New York Society for the Suppression of Vice, January 10, on the charge of using the mails for unlawful purposes, namely, for procuring criminal operations. She was held in $2500 bail, and her daughter-in-law was held for a like amount.

The Charles Frick branch of the library of the Medical and Chirurgical Faculty of Maryland, now has 1693 volumes, 336 having been added during the year. A large proportion of these are new books and monographs. The files of some of the most valuable English journals and hospital reports were completed by purchases made in London. One thousand five hundred and thirty-four books were taken out by readers, and the number of readers frequenting the rooms was 3976 last year.

The sentence of Dr. George C. Worthington, who was convicted of manslaughter, in causing the death by criminal operation, of Amelia A. Miller, and who was given ten years in the penitentiary, has been confirmed by the State Court of Appeals. Strong efforts have been made to keep him out of the penitentiary. He was twice convicted of manslaughter, but the first verdict, in October, 1899, was set aside because one of the jurors was under age.

MASSACHUSETTS.

Dr. Henry C. Williams, Boston. has established a surgeon's room at the Lagrange street police station, equipped with all remedies and appliances for emergency medicine and surgery.

Dr. Frederick S. Ward, for the past two years in charge of the pathological work of the Taunton State Insane Hospital. has resigned his position with that institution and opened an office for private practice in Springfield.

The Boston Board of Health has amended somewhat the regulations with regard to contagious diseases. Any person infected with smallpox, scarlet fever, diphtheria or croup shall be immediately isolated, and shall not leave the room or place until the board of health shall have certified in writing that all danger of communicating the disease is past. No one but the attending physician, nurse and agents of the board of health shall enter an apartment set aside for the treatment of contagious disease, or leave, until the danger is past and a certificate has been issued by the board.

MICHIGAN.

By a recent order of the faculty of the State University, all medical students are required to wear Red-Cross badges, as more strict precautions are enforced against the students of this department who are supposed to be more exposed to infection than those in the other departments of the university.

The State Board of Registration in Medicine in its annual report shows that since January, 1900, 310 practitioners have been granted certificates to practice medicine upon presenting diplomas from reputable medical colleges. Forty-three medical colleges have been placed on the list of reputable medical colleges. Altogether the board has issued certificates to 4250 practitioners. It is estimated that about 600, or at least fully 50 per cent. of the itinerant practitioners have left the state, while there remain about 200 unregistered physicians still in practice. It is said that the ranks are being gradually and surely thinned out, owing to local prosecutions under the new medical act and the difficulty of evading the law.

Proposed bills for better legislation for public-health purposes were approved by the State Board of Health for introduction into the legislature. Among them were those to provide for a state hospital for consumptives, to provide for the testing of all milch cows supplying milk for sale and use in cities and villages, and a proposed amendment to the local quarantine law, to provide for an annual public meeting under the auspices of the local board of health in each township, city and village. The secretary presented the quarterly report of work done in the office, which shows the number of reports of outbreaks of dangerous communicable diseases, concerning which action was taken by the office, during the quarter, to be as follows: Diphtheria, 180; scarlet fever, 259; typhoid fever, 522; measles, 56; whooping-cough, 41; smallpox, 66; meningitis, 120, and consumption, 364. Total for the eight diseases, 1608.

MINNESOTA.

The library of the late Dr. John H. Murphy, St. Paul, has been presented to the Ramsey County Medical Association by his widow.

The Owatonna City Hospital was formally opened for inspection January 5. The hospital has accommodation for twelve patients, with a maximum capacity of seventeen, and is thoroughly outfitted and equipped. Dr. John H. Adair is president of the advisory board.

The State Board of Health met at St. Paul January 15 and elected the following officers: Dr. Franklin Staples, Winona, president; Dr. Henry Hutchinson, St. Paul, vice-president, and Dr. Henry M. Bracken, Minneapolis, secretary and executive officer. The marked increase in the number of cases of smallpox reported in the past year was the chief subject of discussion at the meeting.

MISSOURI.

Two medical students were arrested and fined $50 each at Kansas City, January 16, for not reporting to the board of health a case of smallpox which they were attending.

A resolution was adopted January 9, concurrently by the house and senate, which provides that these bind themselves to appropriate $10,000 for the use of the State Board of Health. The money is to be used by the board to prevent the spread of smallpox, which is prevalent throughout the state.

A committee appointed by the State Medical Association at its last meeting, is in Jefferson City for the purpose of recommending legislation in the interest of the physicians of Missouri. The members of the committee are: Dr. A. W. McAlester, Columbia; Dr. Eugene L. Priest, Nevada; Dr. Frank J. Lutz, St. Louis; Dr. David C. Gore, Marshall, and Dr. Herman E. Pearse, Kansas City.

The State Board of Health adjourned January 7, after electing Dr. C. B. Elkins, of Ozark, president; Dr. J. T. McClanahan, Boonville, vice-president, and L. C. McElwee, St. Louis, secretary. Dr. S. C. James introduced a resolution rescinding the action of the July meeting of the board in Kansas City in 1899, thus making it necessary for the board to recognize the diplomas of all colleges that matriculated students in 1898, and who graduated at the end of the scholastic year of 1901, and to register or license those graduates of any college having a three-years' course.

NEBRASKA.

The diagnosis of smallpox in St. Edward, made by Dr. Jones, has been confirmed by Dr. S. R. Towne, of the State Board of Health, and quarantine established.

Dr. Victor H. Coffman, health commissioner of Omaha, urges the immediate erection of an emergency hospital properly equipped and provided with adequate police protection.

Senator Trompen introduced a bill in the state senate January 15, which legalizes the practice of osteopathy and declares it not to be the practice of medicine as contemplated by the law governing the practice of medicine.

NEW HAMPSHIRE.

The Dover Hospital was incorporated January 18 by eleven ladies of that city. It is to be a charitable association.

The State Board of Medical Examiners has issued licenses to practice to eighteen applicants who were examined December 11 and 12.

Dr. Gustave Lafontaine, Manchester, whose arrest for practicing without a license was noticed in The Journal and whose defense was his lack of familiarity with English, has passed a satisfactory examination, and has been licensed to practice.

NEW YORK.

Dr. Charles C. Duryee, Schenectady, has been appointed a member of the board of health.

Mr. Cotton has introduced a bill to exempt from taxation the property of medical societies in New York and Buffalo.

The Oswego local health board has ordered a general vaccination of school children and teachers. The schools were ordered closed for two weeks.

The estate of the late J. D. Sarven, Tarrytown, has been appraised. It is estimated that by the terms of his will the Presbyterian and St. Luke's Hospitals will each receive $59,140.

Mr. Bell has introduced into the assembly a bill to so amend the general health law, by more specifically defining who are and who are not lawful practitioners of medicine, that there may no longer be any doubt as to the legal status of faith-healers and other similar impostors.

The State Board of Health reports about 75 cases of smallpox in the state. The most serious outbreaks at the present time are at Watertown and Schenectady, although both are under control. One case at Southold, Suffolk county, and the presence of several at Norfolk, St. Lawrence county, and Northville, Fulton county, were reported to the board.

A week ago it appeared as if the long fight over the site for the State Hospital for Consumptives was at an end, and that Raybrook had been finally chosen. It appears now that another sharp wrangle is to take place in the legislature, as a bill has been introduced to compel the selection of the Dannemore site and the building of the hospital by convict labor on state lands.

Buffalo.

Dr. Nelson G. Russell has resigned the position of district physician, and Dr. Herman de Groat has been appointed from the eligible civil service list in his place.

Major Ira C. Brown, Buffalo, who is in the government service in the Philippines, has been placed in charge of the medical supply depot at Iloilo and of the vaccin farm. He is also the disbursing officer for the department.

The health commissioner has issued a proclamation concerning smallpox, and advises general vaccination. A meeting of the health commissioner and district physicians was held to consider the advisability of general vaccination in all private, parochial and public schools.

New York City.

Dr. Hiram N. Vineberg has been appointed adjunct attending gynecologist to the Mount Sinai Hospital.

Register James R. Howe has given $2500 to the Eastern District Dispensary and Hospital Association, Brooklyn.,

Drs. Austin Flint, Jr., and Edward A. Ayers have resigned as attending physicians of the Mothers' and Babies' Hospital.

William T. Wardwell, president of the Red-Cross Hospital, has given $40,000 toward a fund for the erection of a new hospital.

The mortality of Greater New York for 1900 was 70,716, or 4987 more than for 1899, the mortality per 1000 being 20.53 in 1900 and 19.47 for 1899. There was increase of about 50 per cent. in the deaths from measles: 25 per cent. from typhoid fever; 10 per cent. from diphtheria and croup, and more than 100 per cent. from sunstroke.

Since the first case of smallpox was reported on Nov. 5, 1900, there have been 127 cases, with ten deaths. A death from smallpox occurred in Brooklyn a few days ago, and the certificate was signed by a physician who stated that the cause of death was typhoid fever. Asked by the health department to explain this, he said that he had been in doubt about the diagnosis, and had stated it to the best of his knowledge and belief. He said he had seen over 100 cases of smallpox in Russia.

PENNSYLVANIA.

For the second time since the appearance of diphtheria at Mt. Joy, near Lancaster, the public schools have been ordered closed.

The Lycoming County Medical Society held a special meeting at Williamsport, December 30, at which a committee was appointed to draw up resolutions relative to the death of Dr. Louis Schneider.

Dr. Alice Bennett having withdrawn as a candidate for the position made vacant by the resignation of Dr. Susan Tabor, Dr. Mary Moore Wolfe has been elected resident physician of the Norristown Insane Asylum, at a salary of $1500 a year.

Philadelphia.

A new board of trustees of the Medico-Chirurgical College, composed entirely of laymen, was elected January 16.

At the eighteenth annual meeting of the Alumni Association of the Medico-Chirurgical College the following officers were elected: Dr. John Welsh Croskey, president; Dr. Stillwell C. Burns, secretary, and Dr. S. S. Gans, treasurer.

The annual election of officers of the medical staff of St. Mary's Hospital was held January 15, and resulted as follows: Dr. John J. Moylan, president; Dr. Louis F. Love, vice-president, and Dr. Joseph Ross, secretary. It is believed that the new building of this hospital will be completed early in the present year.

RHODE ISLAND.

Dr. Charles W. Stewart and wife, of Newport, have sailed for Europe, en route to Vienna, where Dr. Stewart will take post-graduate work in surgery.

Diphtheria prevails at the Home for Destitute Children at Bristol, R. I., and nine cases have been reported. One of the city schools has been ordered closed.

The Hopeworth Sanatorium, Bristol, a private hospital for nervous diseases, suffered a $6000 loss by fire January 3. Martha Cottage was burned but the main building was uninjured.

In the case of Dr. Joseph Napoleon Roy, Harrisville, mentioned in The Journal of November 17, the State Board of Health has revoked Dr. Roy's certificate, and he promises to appeal to the Supreme Court and to furnish some interesting revelations as to the political aspect of the affair.

GENERAL.

Sanitary inspectors have recently been placed at the ports of Nanaimo, Chemainus and Ladysmith, on the Pacific Coast of British Columbia, for the purpose of inspecting vessels bound from those ports for San Francisco, to prevent the introduction of smallpox into the latter place.

Steps are being taken by the U. S. Marine-Hospital Service to establish a temporary supplemental quarantine station at Venus Point, S. C., on the Savannah River, for the purpose of intercepting cases of smallpox bound to Savannah from the coast islands of South Carolina, where this disease is said to be very prevalent. Inquiry is also on foot to ascertain the extent of this disease in the islands.

The U. S. Marine-Hospital Bureau recently received a report to the effect that four fatal cases of plague had appeared on a vessel arriving at Shields, England, from the Rio de la Plata. Passed-Asst. Surgeon Thomas, on duty in London, was immediately ordered to this point. He also stopped at Hull, England, to investigate a report of plague on the steamship *Friary*, recently from Alexandria, Egypt, and has reported by wire that five deaths from plague occurred among the crew of this vessel en route, and that no further cases have appeared and that all sanitary precautions have been taken.

The death-rate for December, in Honolulu, was 2.85 per cent., or 112 deaths, 32 of whom were females. Of the deaths among males, 21 were due to consumption. The following were the causes assigned: Malarial fevers, 2; typhoid, 3; diarrhea, 1: infantile diarrhea, 1; dysentery, 2; congenital syphilis, 1: septicemia, 1; inanition, 6; laryngeal, mesenteric and miliary tuberculosis, 1 each, and pulmonary, 17; atelectasis, 1: old age, 5; premature birth, 1; congestion, 7, convulsions, 1: senile dementia, 1; paralysis, 1; diseases of the spinal cord and membranes, 1; beri-beri, 2; valve disease of the heart, 4: asthma, 3; bronchitis, 4: croup, 1; edema of the glottis, 1; pleurisy, 1: pneumonia, 13; pulmonary edema, 1; appendicitis, 1; gastritis, 1; gastro-enteritis, 1; hernia, 1; inflammation of intestines, 5; cirrhosis of the liver, 1; peritonitis, 2; acute nephritis, 1; chronic nephritis, 2; uremia, 1; Bright's disease, 1; metritis, 1; puerperal convulsions, 1; puerperal hemorrhage, 1; accidental fall, 1; crushed by dray, 1; poisons, 2: suicide, 2.

PAN-AMERICAN MEDICAL CONGRESS.

The prospects for a large representation of the medical profession of this country at Havana, at the meeting of this Congress, are very promising. Not only will a large number go from the extreme East, but the West will send good delegations. The latest reports from Havana indicate that the health of the city is quite satisfactory, the danger from yellow fever being practically eliminated. The railroad rates are moderately low, the fare from Chicago to Havana and return being $86, which includes berth and meals on the steamer. Those wishing to go via New Orleans should remember that the Morgan line of boats, which has recently been put into service, leaves on Saturday only. Those who wish to go by this route can leave Chicago by the Illinois Central at 8:30 a. m., Friday, February 1, arriving at New Orleans Saturday, February 2, at 9:35 a. m. The boat leaves two hours later and arrives at Havana on the morning of February 4. For other routes see previous issues of The Journal.

CANADA.

The French-Canadian medical men of the province of Quebec are endeavoring to organize a medical congress of the French practitioners of North America, to be held some time next summer. It is fully expected that the outcome of the congress will be the formation of an association of French practitioners for the whole continent. It is understood that the French practitioners of Louisiana are favorable to the undertaking. There are reputed to be 500 French practitioners in the United States, and a little over 1000 in the province of Quebec.

The relation, if any, between the manholes and the prevalence of diphtheria in Toronto is now going to receive careful investigation and observation on the part of the medical health officer of the city. Dr. Sheard has had prepared a large map of each of his inspectors' districts; and where a case of diphtheria occurs, it will be noted if a manhole is in the neighborhood, and also the class of street pavement. In this way the influence of local conditions will be investigated. It is expected that the scavenging of the city will also soon be placed under the medical department.

Dr. Clarke, superintendent of the Kingston Asylum for the Insane, has been appointed a commissioner to investigate the workings of the asylum at New Westminster, British Columbia.

A movement is on foot to induce the War Office of England to create places for a certain number of Canadian nurses in connection with the medical corps of the British army. A great many young Canadian women are trained at the hospitals here each year, but the field is limited, and it is thought that the war office ought to be able to avail themselves of our nurses, many of whom have shown themselves capable in the South African campaign.

MEDICAL DEFENSE FUND.

The regular meeting of the medical society of the district of St. Francis of the province of Quebec was held on January 11, under the presidency of Dr. Brown, of Richmond, Quebec. The Medical Defense Union of this association is being endorsed by all the medical men in that district, and several Montreal men have expressed a wish to become members. The question of physicians being appointed for fraternal orders was the principal topic of discussion. An effect will be made to do away with the present system of appointments, and the system of allowing each member of a lodge to choose his own physician in time of sickness, the lodge to pay the doctor's bill, substituted in its stead. It was pointed out that in the great majority of cases the lodges paid out more to the appointed physician than if paid under the latter scheme. The doctors of the City of Sherbrooke present decided to call a meeting of all the medical men in that city, and have them enter into an agreement not to accept any regular appointment in lodge except as examining physician. The association will shortly tender a banquet to Surgeon-Major Worthington in recognition of his work in South Africa.

FOREIGN.

The Vienna *Medicinische Wochenschrift* celebrates its semicentennial by a special number, containing "Aphorisms," and congratulations from its numerous friends and collaborators, who testify to its fidelity to the service of the medical sciences and its dignified course through its half century of existence.

The Paris Medical Club gave an entertainment recently in which the music, songs and compositions recited were all by French physicians of the day, many of them popular in wide circles at home and abroad. They were all rendered by professional artists. Among them were Richelot's melodies, Prof. Richet's famous fables, Cazalis' "Mal d'Aimer"—the latter better known by his pseudonym," Jean Lahor"—and Dr. R. Blondel's musical compositions.

MAGNETIC HEALING IN FRANCE.

A recent decision of the supreme court in France is considered a great triumph for the profession, as it is the first organized effort of physicians to put down quackery in that country. It is declared illegal practice of medicine for any one not having been granted a diploma as a physician, to apply magnetism to the treatment of patients. Three years ago the Medical Syndicate at Angers commenced legal proceedings against a magnetic healer, accusing him of the illegal practice of medicine. The charlatan in question treated his patients by making passes over them and applying "magnetized cotton." The local court acquitted the healer and the syndicate appealed. The superior court confirmed the decision that magnetism could not be considered a treatment. The syndicate then appealed to the supreme court, supported morally and financially in its efforts by the Union des Syndicats Médicaux de France, while the magnetic healers in the country formed a powerful combination against them. The decision of the Cour de Cassation, handed down Dec. 30, 1900, states that the treatment of diseases by magnetism is to be considered the practice of medicine and should only be done by medical men. "The syndicate may justly be proud of its perseverance and success," one confrère editorially exclaims, "for if physicians suffer from these practices, the patients suffer still worse—they die."

LONDON LETTER.

THE ANTI-TUBERCULOSIS MOVEMENT.

The anti-tuberculosis crusade, which was begun more than two years ago, has made great progress. In the profession the open-air treatment has come to be regarded as the treatment par excellence. Among the general public, by means of meetings, pamphlets, etc., a great deal of vital information has been diffused as regards the necessity for providing sanatoria and the importance of hygienic measures to prevent contagion. The National Association for the Prevention of Tuberculosis is the mainspring of this movement for enlightening the public and obtaining the support of leading men in the country which is necessary for the success of any reform. A large number of private sanatoria for carrying out the open-air treatment of consumption have now been provided, but for the poorer part of the population who can not afford to pay for such treatment the work of providing it free or at a small cost, though making good progress, is still in its earliest stage. The compulsory notification of consumption is a measure which is certain to be shortly enacted. In the meantime a number of sanitary authorities have adopted a system of voluntary notification. The National Association for the Prevention of Tuberculosis is now issuing to corporations, urban and rural councils, etc., a pamphlet containing suggestions as to voluntary notification and provision of open-air treatment for pauper consumptives. Under the notification system, cases are isolated and insanitary areas and houses are improved. Information is also given as to the cost of erecting sanatoria, disinfection of consumptives' dwellings, and the improvement of cowsheds. A large number of hospitals now provide open-air treatment, either free or at a small charge. Boards of health are now building sanatoria or maintaining beds in existing ones, or adapting special wards in the infirmaries to the open-air treatment. Another outcome of the antituberculosis movement is:

THE BRITISH CONGRESS ON TUBERCULOSIS.

The congress will be opened on July 22, 1901, and will sit from that date until the 26th. Every British colony and dependency has been invited to send delegates, and the governments of foreign countries to send representative men of science, who will be guests of the congress. Consumption and other forms of tuberculosis, though preventable and controllable, cause about 60,000 deaths annually in the United Kingdom. Probably thrice this number of persons are constantly suffering from one or other form of the disease. The object of the congress is to exchange the information and experience gained throughout the world as to methods available for stamping out the disease. Papers will be read and clinical and pathological demonstrations will be given. The museum, which will be a special feature of the congress, will contain pathological and bacteriological collections, charts, models, and other exhibits. Authorities of this and other countries will be invited to supply documents on the historical, geographical and statistical aspects of the subject. As a result of the papers and discussions practical resolutions will be formulated, which will serve to indicate the measures best adapted for the suppression of tuberculosis. The work will be divided into four sections, as follows: Section 1, state and municipal; section 2, medical, including climatology and sanatoria; section 3, pathology, including bacteriology; section 4, veterinary.

DEATHS FROM ARSENICAL BEER.

A record of the inquests held in Manchester alone, respecting deaths supposed to be due to arsenical poisoning from consumption of impure beer, shows in a striking manner the seriousness and extent of the epidemic. Twenty-one inquests have been held; in 8, death was due to arsenical poisoning, in 7, to natural causes, but there were arsenical symptoms; in 2, death was accelerated by the poison. At one of the inquests Dr. Reynolds, visiting physician to the Manchester workhouse, to whom is due the credit of discovering the cause of the outbreak of peripheral neuritis in Manchester, gave evidence as to how he arrived at his conclusion, which is most interesting as an example of sound medical reasoning. He observed that herpes occurred in some of the cases of peripheral neuritis. He therefore concluded that the herpes and the neuritis were due to the same cause. Now, the only drug which he knew produced herpes was arsenic. He, therefore, concluded that the patients must be taking arsenic in some way. As the only common factor was the beer he suspected that was the source, and on analysis found that it contained arsenic. In one of the fatal cases of arsenical poisoning the lungs were dropsical and the liver was much enlarged and in a condition of chronic inflammation. But no traces of arsenic could be found in the viscera. In another case an appreciable quantity of arsenic was found in the liver, kidneys and heart. Two deaths from arsenical poisoning have occurred at Liverpool.

THE RELATION OF MASTITIS TO TUMOR FORMATION.

At the Pathological Society Mr. F. T. Paul read an important paper on this subject. He said that the tendency of chronic mastitis to end in tumor formation had more impressed him every year. Cancerous breasts almost constantly showed microscopic changes indicating preceding chronic mastitis, and breasts removed for simple chronic mastitis frequently presented appearances suggestive of the commencement of cancer. This *same* was true of innocent tumors, even of those of early life. "Involution mastitis" commenced as a chronic interstitial inflammation and passed into a cirrhotic state, accompanied by cystic alterations in the acini and generally by considerable increase in the gland elements. At the stage of involution in some cases resolution took place; in others the irritation continued. especially in the peri-acinous connective tissue and after prolonged stimulation might end in the growth of a fibroadenoma. In other cases or in other parts of the same organ the epithelium responded chiefly, and intracystic papilloma or carcinoma might originate. He concluded that the association of chronic mastitis with adenoma in early life and with cystic and other varieties found later, its almost constant presence in conjunction with cancer, the marked bilateral mastitis which preceded bilateral cancer, and the appearances seen under the microscope in chronic mastitis, taken in conjunction with clinical experience, showed that chronic mastitis. if not the immediate. is at any rate the frequent, predisposing cause of tumor change and renders excision desirable in all marked or inveterate cases.

Marriages.

Otis Higgins, M.D., to Miss Blanche Dicks, both of Lebanon, Ind., January 9.

Charles A. Kearney, M.D.. Farley, Iowa, to Miss Caroline Freeman, December 25.

Greene D. McCall, M.D., Fulton, Mo., to Miss Annie Baskett, Mexico, Mo., January 9.

H. Frank Preston, M.D., Utica, N. Y., to Mrs. Anna McFarland, Altoona, Pa.. November 7.

G. Duffield Stewart, M.D., Detroit, Mich., to Mrs. Katharine Fletcher, Mt. Clemens, January 3.

Jacob S. Green, M.D., Alameda, Cal., to Miss Gertrude Bialoglowski, Oakland, Cal., January.

Thomas C. McNamara, M.D., Hoboken, N. J., to Miss Minnie Eloise Gallagher, Brooklyn, N. Y., January 23.

John H. Burkhalter, M.D., U. S. M.-H. Service, Mobile, Ala.. to Miss Lillian Johnson, Thomson, Ga., January 2.

John S. Meserve, M.D., Dover, N. H., to Miss Edith Conner, daughter of Dr. Phineas S. Conner, of Cincinnati, January 1.

B. F. Sandow, M.D., government physician, Waimea Kauai, Hawaiian Islands, to Miss Eula Elston, Berkeley, Cal., January 1.

John B. Dennis, M.D., ensign U. S. navy, stationed at Philadelphia, to Miss Adelaide A. Ware, of Fortress Monroe. January 8.

Deaths and Obituaries.

Charles Wesley Purdy, M.D., Queen's University, 1869; Honorary Fellow of the Royal College of Physicians and Surgeons of Ontario, 1888; LL.D., 1898, Queen's University, Kingston, Ontario, died January 20 from uremia, at his home in Chicago, aged 54. He was born in Collins Bay near Kingston, Ontario. and took his academic course in Victoria University, Montreal. He practiced for two years in Hastings, Ontario, and then came to Chicago. He was successively house physician at the Grand Pacific and Auditorium Hotels until 1893, when he moved to his home on Twentieth street, in which he lived thereafter. For many years he had made diseases of the kidney his specialty, and was an accepted authority on this branch of medicine and on analysis of urine. His contributions to the literature on these subjects are numerous and valuable. His work on *uranalysis*, which has gone through several editions, is a standard; and his text-books on Bright's disease and diabetes are also considered authoritative. He was a member of the faculty of the Post-Graduate Medical School of Chicago from its organization, for several years, but never enjoyed didactic teaching, preferring to make laboratory researches and to publish their results. He was a member of The American Medical Association, British Medical Association, Illinois State Medical Society and Chicago Medical Society, and was a charter member of the Chicago Society for Internal Medicine. He was an indefatigable worker, and several months ago suffered from nervous prostration, attended by *insomnia*, etc. He went away for rest and recuperation, but without avail. He returned from Alma, Mich., on January 15. Three days later he was taken ill, and on the morning before he died, passed into a comatose condition from which he did not rally.

Benjamin F. Swafford, M.D., for many years a prominent physician and surgeon of Terre Haute, Ind., died at his home in that city January 8, of diabetes, aged 67. He was graduated from Rush Medical College in 1858, and was prosector to the chair of anatomy during the years 1857-1858. At the outbreak of the Civil War he entered the service as surgeon of the Eleventh Indiana Cavalry, and later had charge of Field Hospital No. 1 at Eastport, Miss., until May, 1865. He then entered civil practice at New Goshen, Ind., removing to Terre Haute in 1874, where he continued to practice until his death. He enjoyed a large, successful and lucrative practice and was one of the leading medical men of the country. He was a member and ex-president of the Vigo County Medical Society. a member of the Aesculapian Society of the Wabash Valley, and for years an active member of the Indiana State Medical Society and of The American Medical Association

David N. Rankin, M.D., *Jefferson* Medical College, Philadelphia, 1854, an old and honored member of The American Medical Association, State and County Medical Societies, and of the Laryngological Association: a delegate to the Berlin Congress in 1890; a surgeon of the volunteer army in the Civil War, and prominent alike socially and *professionally in* Allegheny, from pneumonia, after an illness of three weeks, at his home, at Shields Station, Pa., January 1.

Lieut. Louis P. Smith, assistant-surgeon U. S. A., College of Physicians and Surgeons, N. Y., from septicemia following an operation for appendicitis at the First Reserve Hospital, Manila, P. I., January 8, aged 30. Dr. Smith was the first medical officer to land in Cuba, and built the first shore hospital. In November, 1899, he sailed for the Philippine Islands and was acting brigade surgeon at Dagupan.

Wilbert K. Sloan, M.D., College of Physicians and Surgeons. Keokuk, Iowa, 1875, a prominent physician and *citizen of* Moline, Ill., a member of the local, state, Illinois-Iowa district societies and of The American Medical Association, and for twelve years a member of the board of education, at his home. January 1, from intestinal tuberculosis, after a lingering illness, aged 53.

Benjamin Franklin Leonard, M.D., University of Maryland, 1876, a member of the staff of the Maryland General Hospital, surgeon to the Hebrew Hospital and Asylum, and a member of The American Medical Association, at his home in Baltimore, from pneumonia, after an illness of six days. April 10, 1900, aged 53.

Cyrenius C. Powell, M.D., Albany (N. Y.) Medical College, 1864, one of the most prominent physicians of Southeastern Iowa, at his home in Ottumwa, January 6, from septic infection, after an illness of three weeks. The Wapello County *Medical Society*, at a special meeting, January 8, adopted resolutions of sympathy.

Robert A. Truxillo, M.D., Kentucky School of Medicine, Louisville, 1891, of Assumption Parish, La., from smallpox. contracted while in charge of the Levee Convict Camp on the east bank of Bayou Lafourche, January 7.

Henry Foster, M.D., Western Reserve University, Cleveland. Ohio, 1848, proprietor of the Clifton Springs Sanatorium, at his home in *Clifton* Springs, N. Y., suddenly, *from* heart disease, January 15, aged 79.

Isaac Newton Thacker, M.D., Ohio Medical College, 1840. a pioneer in medicine *in Ohio* and for nearly half a century an active practitioner, from paralysis, *at* his home in Defiance. Ohio, January 8, aged 89.

H. G. Tope, M.D., surgeon of the Eightieth Ohio Infantry in the Civil War, and since that time in practice at Lamartine, Ohio, at his home in *that place*. *December* 25, aged 62.

James Henderson Hale, M.D., Vanderbilt University, Nashville, Tenn., 1892, from a bullet-wound accidentally received, at his home in Osceola, Ark., January 9, aged 30.

George Schlagenhauf, M.D., Washington University, St. Louis, 1875, from heart disease, after a long illness, at his home, Altamont, Ill., January 9, aged 53.

James P. Epes, M.D., University College of Medicine, Richmond, Va., 1898, in New York City after an operation for appendicitis, January 11, aged 30.

Nathaniel S. Sievers, M.D., University of Pennsylvania, 1867, at his home in Salem, N. C., after an illness of several years, January 12, aged 60.

William P. Connally, M.D., Tennessee Medical College, Knoxville, 1894, of Atlanta, at Abilene, Texas, from consumption, January 13, aged 26.

Adolphus J. Dennis, M.D., Kansas City Medical College, 1900, from consumption, January 5, at St. Joseph's Hospital, Kansas City, aged 23.

Charles B. Borden, M.D., Bellevue Hospital Medical College, New York, 1877, from pneumonia, January 9, at his home in Stamford, Conn.

Horace Halbert, M.D., University of Buffalo, N. Y., 1851, at his home in Canastota, N. Y., January 11, after a long illness.

Albert H. Snead, M.D., College of Physicians and Surgeons, N. Y., 1858, at his home in Waco, Texas, January 8, aged 63.

William A. Wright, M.D., University of Nashville, Tenn., 1857, at his home in Rives, Tenn., January 10, aged 75.

Correspondence.

Self-Castration.

Camden, N. J.

To the Editor:—Emil L., a young white man, was brought to the Cooper Hospital about midnight of September 26. A couple of hours previously he had castrated himself, removing the entire scrotum. When he came into the hospital his appearance indicated that he had lost considerable blood, and the severed vessels were still bleeding. Examination revealed that the scrotum had been amputated close to the urethra, and the spermatic cords were retracted into the external abdominal rings. The vessels of the cords were ligated and the cutaneous flaps of the wound were sutured in the median line. A week subsequently the wound had healed by first intention; and when cicatrization and contraction are complete there will remain only a median raphe, in close contact with the penis.

For a day or two after admission the man was reticent, and it was difficult to induce him to speak of the act or of the causes that impelled him to it. But, later, he became more communicative, and in describing his operation he said he first tied a cord around the scrotum, above where he intended to cut, believing this was necessary to save him from a dangerous loss of blood. He then seized the scrotum and testicles in his left hand, and with a razor cut from above downward, with a sawing motion, severing successsively all the structures. He said the "tendons" were more difficult to cut than the skin; that there was not much bleeding at first, but it became more severe in a few minutes. When asked if he was not tempted to abandon the procedure when he felt the pain of the cut, he replied that the pain was not very great, and he thought the flow of blood tended to prevent much suffering. He observed that the cord placed around the scrotum to prevent bleeding did not remain in position after the parts were severed, and to this fact he attributes the greater flow of blood that subsequently ensued. To the remark that he might have amputated the penis in his haste, he laughingly replied that he was careful not to do that.

A native of Switzerland, 27 years of age, he has resided in this country fourteen lears; a florist by occupation. His father, six brothers and three sisters are living, his mother dead, the cause of her death unknown. From his description the members of his father's family were probably of a melancholy temperament and easily excited. Concerning himself, he says he was always despondent, that his employers did not use him right; that he was nervous, and his memory poor. He always had some pain in his testicles, and frequently pain in the back. He never practiced masturbation; never had sexual intercourse, and never experienced strong desire for it. Involuntary emissions occurred at intervals of a month or six weeks, with the result that the pain in the back and testicles became less severe for a short period. Socially, he was always a recluse, and never associated with the opposite sex.

When questioned as to the immediate motive that prompted him to mutilate himself, he replied that it was because of the pain he experienced, and he thought by this means to obtain relief. He felt that his lack of success in life and his inability to please were due to the condition of his sexual organs, and he hoped by removing the offending members to obtain relief from the various influences that made him unhappy and a constant sufferer. He further said he had for years meditated on the desirability of removing the testicles in certain individuals, to prevent the transmission of undesirable traits to posterity. He had no knowledge of the Skopzi, and is not familiar with the practices of that sect.

On the seventh day following the removal of the testicles an involuntary seminal emission occurred, during sleep, but was unattended with a lascivious dream; it caused him to awake immediately. The stain on the linen was examined ten hours later, and presented all the characteristics of dried semen. Washed with dilute acetic acid, a slide was moistened with the resulting mixture, and the microscope revealed the presence of spermatozoa, but not in large quantities, there being, on an average, three to five in the field of observation. Following the emission, there was considerable pain in the wound.

The testicles, wrapped in a handkerchief, were taken with the patient to the hospital. They were of normal size and consistency, and minute inspection reveals that they were free from disease.

Daniel Stroch, M.D.

Comments on Dr. Deaver's Article "Walled Off."

Melton, Del., Jan. 19, 1901.

To the Editor:—Dr. Deaver's article in The Journal of A. M. A., of January 5, is interesting as well as instructive. We all appreciate an early diagnosis as much as early treatment, and his statement "Let me insist that you have your cases of appendicitis operated on, yes, immediately after the onset of the initial pain," seems rather strong. For my own benefit and also for a large number of the profession, we would like the Doctor to give us the symptoms of the initial pain, its character and location. The symptoms of appendicitis are so varied and deceptive that I am sure many hesitate to operate, owing to the fact of being unable to arrive at an early positive diagnosis. We are inclined to think that should the Doctor's advice be taken many abdomens would be opened and normal conditions in relation to the appendix be found. I appreciate very much the Doctor's article and am not writing in the spirit of criticism, but as a seeker after truth, appreciating, as the Doctor does, the value of an early operation if one is necessary, but seeking for infallible signs whereby one may not err in an early diagnosis. Could we be as positive of the symptoms and physical signs of appendicitis as we are of empyema or pleurisy with effusion then we would not hesitate to follow the advice. Every physician feels a great responsibility resting upon him when called to cases in which the symptoms are indicative of appendicitis—to operate or not to operate is the question. He asks: Am I warranted in subjecting the patient to the dangers of an operation while some doubt exists in regard to the diagnosis? We believe in many cases it is impossible to make an early diagnosis unless the abdomen be opened. The Doctor's advice may apply very well to hospital, but the same can not always be carried out in private, practice. For the sake of diagnosis are we justified in opening the abdomen if no diseased appendix is found? . . . Many will frankly admit that they can not make a diagnosis of appendicitis in its early stage, and while having read all the literature at my command on the subject I admit I could make a better diagnosis after the abdomen was opened than before. We would like to hear from the Doctor again on the early symptoms and positive diagnosis of the disease.

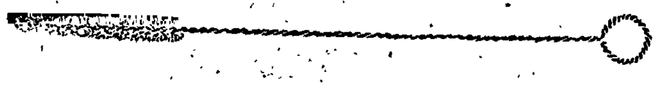
R. B. Hopkins, M.D.

New Instruments.

A New Method of Cleaning the Cervical Canal.

GEORGE W. NEWTON, M.D.
Professor of Gynecology, Chicago Clinical School; Instructor in Gynecology, College of Physicians and Surgeons; Attending Gynecologist, West Side Hospital.
CHICAGO.

The difficulty experienced in trying to remove the secretion from the cervical canal before making applications thereto caused me to seek other methods than theories heretofore advised. I had a brush made as shown in the cut and the ease with which the canal can be cleaned is really surprising. It does its work perfectly, and removes equally as well the thick, yellow, gelatinous gonorrheal plug as it does one of the hematogenous variety of endocervicitis. The brush is cylindrical in shape, 1½ in. long, ¼ in. in diameter, tapering to 3/16 in. If the patient is a nullipara and has a small cervical canal a smaller brush should be used. With a pair of scissors it is a simple matter to trim the bristle off to any size desired. Several sizes should be kept on hand; as they are very inexpensive the cost is a matter of small consideration. The brush is inserted into the cervical canal to the internal os, revolved once or twice and then withdrawn, and the membrane lining the canal will be clean. The discharge becomes entangled in the meshes of the brush and adheres to it as it is withdrawn. To clean the brush hold it under running water for a few moments. It can be sterilized in the usual manner. Although simple, this brush will be found to be a very useful instrument. The uselessness of applications to the cervical canal is often due to the fact that the medicament is not applied to the membrane but to discharge which filled the canal and which it was impossible to remove. Five cases of gonorrheal endocervicitis have been practically cured by applications to the canal after first cleaning the membrane by my brush. These brushes may be obtained at the instrument shops.

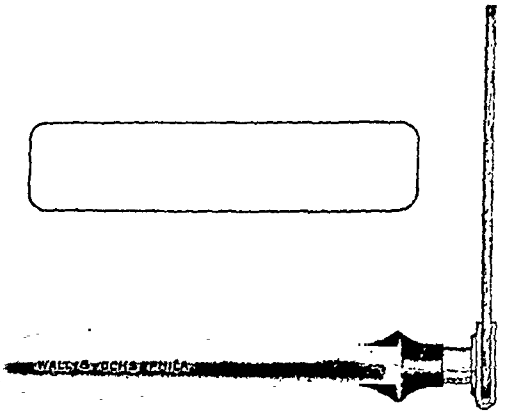


A New Tongue-Depressor.

G. ALVIN HILL, A.M., M.D.
PHILADELPHIA.

Any metallic tongue-depressor, however carefully made, will, after a time, become unsightly from the wearing off of the plating, and no amount of cleaning will give it the appearance of being clean; so fastidious patients are very apt to look askance at it. Another annoying objection to all instruments made of metal not corrugated or roughened is their tendency to slip backward or sidewise on the tongue, causing irresistible gagging and a necessary pause in one's examination or operation, not to mention a less docile state of that member afterward.

With the instrument here described these unpleasant features are entirely obviated. The spatula is of hard, nicely finished wood, which, on being placed on the tongue, adheres to it, so that considerable forward traction can be made and thus effectually draw the base of that organ away from the fauces, allowing more room for inspection or such applications as may be desired. After use, it is removed from the handle and thrown away or laid aside and a fresh one used for the next patient who, seeing this procedure, is impressed with the cleanliness of the operator and not infrequently comments on it. These little slips of wood are cheap and easily obtained from the makers. It is generally my custom, however, after using a few dozen of them—rejecting all that have become stained by drugs, such as silver or iodin—to scrub them in soap and water and then subject them to a vigorous boiling for a half hour or more, and after rinsing in clean water allow them to dry, when it will be found that they are as perfect as at first and even whiter.



There can be no question as to their cleanness and aseptic condition after this treatment.

The adhesion to the tongue, the freedom from liability to gag the patient, and their clean and aseptic quality so satisfactory to both physician and patient are the chief merits of this instrument.

Miscellany.

The Support of Medical Societies.—At the beginning of the New Year and at the beginning of the new century we extend to our readers and friends a cordial greeting and offer them our best wishes for prosperity and happiness. In our last issue we called attention to a few of the unsolved problems in medicine, the solution of which we expressed the belief would be accomplished in the near future. We desire at this time to call attention to a matter which we have frequently urged before, and the importance of which to the welfare of the profession of medicine is so great that no apology is needed for bringing it up again. We refer to the proper and complete organization of the profession through its medical societies. Every reputable physician should belong to three medical societies—his county society, his state society, and the AMERICAN MEDICAL ASSOCIATION. In many country districts the counties are not populous enough to support a county medical society, but there is usually a district society, which takes its place. The county societies should be, and usually are, auxiliaries of the state society, and all of the state societies are auxiliary to the AMERICAN MEDICAL ASSOCIATION. We have, then, an ideal scheme for perfect and complete organization, and there is only lacking a sufficient appreciation on the part of many individuals in the profession of the importance of becoming a part of this organization, and thereby increasing its power; and this increase in power means a direct benefit in many ways to every practicing physician. An ideal method of organization, but one which is perhaps not practical in such a large country as this, would be to have the AMERICAN MEDICAL ASSOCIATION become the veritable parent society and have membership in the association convey membership in the state and county societies; the dues all being paid to the Association and a proper adjustment made through its treasurer to provide for the expenses of the local societies. Ten dollars a year would undoubtedly be a sufficient membership fee, to include all the expenses and to furnish each member with one of the best weekly medical journals in the world. There are in Minnesota not far from fifteen hundred reputable practicing physicians who are eligible to membership in the AMERICAN MEDICAL ASSOCIATION and in the Minnesota State Medical Society. Of this number less than five hundred, not 33 per cent., are members of the state society, and only about two hundred, or less than 14 per cent. belong to the National Association. These percentages seem ridiculously low, and, yet we believe the figures will be found about the same in other states. The St. Paul meeting of the AMERICAN MEDICAL AS-

SOCIATION next June will, we hope, be marked by a large accession to its membership by members of the profession in Minnesota, and we also hope that many of them will take the opportunity to join the state medical society, which meets in St. Paul at the same time. It seems hardly necessary to rehearse these advantages, both to the individual physicians and to the profession as a whole, which result from membership in and from the general support of, the representative medical societies. We believe that most medical men recognize and appreciate these advantages, and yet many of them—from perhaps carelessness, procrastination or from some other equally inexcusable reason, or for no reason at all—do not join these societies, and by their failure to do so they deprive the profession to which they belong of the support which it has a right to expect from every one of its members. We urge every one of our readers, who is thus derelict in his duty, to delay no longer, but to make application at once for membership in the AMERICAN MEDICAL ASSOCIATION, and then to begin to make his plans to attend the St. Paul meeting. The requisites for membership are very simple and to those who do not know what they are we shall be very glad to furnish the necessary information. We would add that as the fiscal year of the Association begins in January, the present month is the most convenient time to join and to begin to receive THE JOURNAL with the commencement of the first volume of the 20th century. —*St. Paul Med. Journal.*

Observations on Diseases in the Tropics.—Major Charles F. Mason, surgeon, 26th U. S. Vol. Infantry, in a report to the Surgeon-General of the Army, tabulates the results of his experiences in Porto Rico and the Island of Panay as follows:

	In Porto Rico.	In Panay.
Filariasis	common in natives	rare or absent
Ankylostomiasis	common in natives	rare or absent
Chiggers	common in soldiers	rare or absent
Syphilis	common in natives and soldiers	rare or absent
Malarial fevers	common in soldiers	uncommon
"X" fever	common in soldiers	rare or absent
Beri-beri	rare or absent	common in natives
"Y" fever	rare or absent	common in soldiers

The fever which he calls X, as denoting his ignorance of its nature, was evidently specific. It began suddenly with chilly sensations, high fever, nausea and frequent vomiting, constipation and headache. In five to seven days the temperature fell to normal with slow pulse, jaundice and albuminuria. The patients appeared very sick but always recovered. "Y" fever occurred in Panay epidemically at the end of the dry season. It also was evidently specific, beginning abruptly with chilly sensations, headache, rheumatic pains and high fever, which ended by crisis with profuse sweating and marked weakness. There was no eruption, no secondary fever, no jaundice. The patients recovered, convalescence being often attended with obstinate neuralgia. This was often called dengue, but it frequently occurred in patients only recently recovered from an attack of the latter disease. Dysentery prevails in Panay throughout the year, but with a marked increase in the number and severity of the cases at the beginning of the rainy season, which reaches its maximum about the end of August. It is by far the most serious disease which attacks the white soldier in the tropics, both as regards its mortality and its invaliding effects. Out of 32 deaths from disease in the 26th U. S. Vol. Infantry during its first year of service in the Philippine Islands, 10 were from dysentery and its complications and 10 more from typhoid fever. Boils, abscesses and leg ulcers are very common, the latter especially during campaign when it is impossible to keep the underclothing clean; though not dangerous to life these seemingly trifling ailments put a large number of men out of service temporarily and correspondingly swell the sick report. Suppurative inflamation of the middle ear with perforation of the drumhead is of frequent occurrence; it is insidious in its commencement, often deafness and a sudden discharge of pus being the first symptoms noticed; upon examination an acute catarrhal pharyngitis is usually found.

Societies.

COMING MEETINGS.

Medical Society of the Missouri Valley, Omaha, Neb., March 21, 1901.

Medical Society of the State of New York, Albany, Jan. 29-31, 1901.

Pan-American Medical Congress, Havana, Cuba, Feb. 4, 1901.

Tri-State Medical Association of the Carolinas and Virginia, Richmond, Va., Feb. 26, 1901.

The Associated Health Authorities and Sanitarians of Pennsylvania, Harrisburg, Feb. 6-7, 1901.

THE GOLDEN BELT MEDICAL SOCIETY held its midwinter meeting at Abilene, Kan., January 9, and elected Dr. James R. Crawford, Salina, president, and Dr. Samuel W. Shenck, Solomon, secretary.

THE ORANGE COUNTY (Cal.) MEDICAL SOCIETY met January 2, and elected Dr. Howard S. Gordon, Westminster, president; Dr. Francis M. Bruner, Santa Ana, vice-president, and Dr. John L. Dryer, Santa Ana, secretary.

THE ST. JOSEPH (Mo.) MEDICAL SOCIETY, at its January 8 meeting, elected Dr. John M. Bell, president; Dr. Thompson E. Potter, vice-president; Dr. Wallace B. Deffenbaugh, secretary, and Dr. Perry P. Fulkerson, treasurer.

THE PASADENA (Cal.) MEDICAL SOCIETY held its annual meeting January 9. Dr. George E. Abbott was elected president; Dr. Henry H. Sherk, vice-president, and Dr. John E. Jones, re-elected secretary and treasurer.

THE JACKSON COUNTY (Ala.) MEDICAL SOCIETY held its annual meeting at Scottsboro, January 5, and elected Dr. James W. Knowlton, Paint Rock, president and county health officer, and Dr. William C. Mapes, Scottsboro, vice-president.

THE NEW HAVEN (Conn.) MEDICAL SOCIETY held its annual meeting January 2, and elected Dr. Frank H. Wheeler, president; Drs. Jay W. Seaver and Frederick Bellosa, vice-presidents, and Dr. Alfred G. Nadler, secretary and treasurer.

THE BAY COUNTY (Mich.) MEDICAL SOCIETY met at Bay City, January 14, and elected Dr. Henry B. Landon, president; Dr. John W. Coughlin, vice-president; Dr. Morton Gallegher, secretary, and Dr. Charles H. Baker, treasurer, all of Bay City.

THE LAWRENCE COUNTY (Ala.) MEDICAL SOCIETY elected Dr. C. S. Chenault, Mount Hope, president; Dr. Edgar T. Simms, Hettsboro, vice-president, and Dr. William J. McMahon, secretary and county health officer, at its January 9 meeting.

THE CAMDEN CITY (N. J.) MEDICAL SOCIETY, at its meeting January 9, elected Dr. Joel W. Fithian, president; Dr. W. A. Casperson, vice-president; Dr. Sylvan G. Bushey, secretary; Dr. William H. Pratt, treasurer, and Dr. Joseph H. Willis, librarian.

THE WINNEBAGO COUNTY (Ill.) MEDICAL SOCIETY held its annual meeting in Rockford, January 8, and elected Dr. Thomas N. Miller, president; Dr. Paul L. Markley, vice-president, and Dr. Sanford R. Catlin, secretary and treasurer, all of Rockford.

THE MANITOWOC COUNTY (Wis.) MEDICAL SOCIETY held a meeting January 15, at which the following officers were elected: Dr. William G. Kemper, Manitowoc, president; Dr. Louis Falge, Reedsville, vice-president, and Dr. Herbert Thurtell, Manitowoc, secretary.

THE AUGUSTA (Ga.) MEDICAL SOCIETY held its annual meeting January 8, and re-elected Dr. Theodore E. Oertel, president; Dr. William Z. Holliday, vice-president; Dr. W. Clifton Lyle, secretary; Dr. Eugene E. Murphey, treasurer, and Dr. Louis W. Fargo, librarian.

THE NASHUA (N. H.) MEDICAL ASSOCIATION held its annual meeting, January 8, and elected Dr. Herbert L. Smith, president; Drs. Sam S. Dearborn and Augustus Guertin, vice-presidents; Dr. Charles E. Congdon, treasurer, and Dr. Ella Blaylock Atherton, secretary.

THE BALTIMORE MEDICAL AND SURGICAL ASSOCIATION, on January 14, elected the following officers for the ensuing year: Dr. Charles G. Hill, president; Drs. Edward E. Gibbons and E. B. Tenby, vice-presidents; Dr. Eugene Lee Crutchfield, secretary, and Dr. D. Z. Dunott, treasurer.

THE CLINTON COUNTY (Ia.) MEDICAL SOCIETY held its annual meeting at Talladega, January 8, elected Dr. Benjamin B. Fairchild, Jr., was elected president; Dr. Edward L. Martindale, vice-president; Dr. David T. Nicoll, secretary and treasurer, and Dr. Christian Jonsson, librarian.

The Talladega County (Ala.) Medical Society, at its annual meeting at Talledega, January 8, elected Dr. Benjamin B. Simms, president; Dr. Jason S. McCants, vice-president;. Dr. William G. Harrison, secretary and county health officer, and Dr. Eugene P. Cason, treasurer, all of Talladega.

The Alameda County (Cal.) Medical Society, on January 8, elected Dr. Hubert N. Rowell, Berkeley, president;. Dr. Edmund J. Overend, Oakland, vice-president; Dr. Myra W. Knox, Oakland. secretary; Dr. Carl R. Krone, Oakland, treasurer, and Dr. Edward N. Ewer, Oakland, librarian.

The Tulare County (Cal.) Medical Society met in Visalia, January 3, and elected Dr. Alexander L. Wilson, Tulare, president; Drs. Harley P. Mathewson, Visalia, and Robert E. L. Morton, Dinuba, vice-presidents: Dr. Thomas J. Patterson, Visalia, secretary, and Dr. F. A. Combs, Visalia, treasurer.

The Elkhorn Valley (Neb.) Medical Society met at Norfolk, January 9, and elected Dr. P. H. Salter, Norfolk, president; Drs. John P. Gilligan, O'Neill, and H. L. Kindred, Meadow Grove, vice-presidents; Dr. Archibald L. Muirhead, Winside, secretary, and Dr. William H. H. Hagey, Norfolk, treasurer.

The Hartford (Conn.) Medical Society, at its annual meeting, January 7, elected Dr. George R. Shepherd, president; Dr. William M. Hudson, vice president; Dr. Joseph E. Root, secretary; Dr. George N. Bell, assistant secretary; Dr. George K. Welch, treasurer, and Dr. Frederick T. Simpson, librarian.

The Jackson County (Ia.) Medical Society held its annual meeting at Maquoketa, January 15, at which Dr. George O. Johnson, Maquoketa, was elected president; Dr. John C. Dennison, Bellevue, vice-president; Dr. James O. Ristine, Iron Hills, secretary, and Dr. Willis A. Scott, Maquoketa, treasurer.

The Omaha Medical Society elected officers January 8 as follows: Dr. Byron B. Davis, president; Drs. Gertrude Cuscaden and Rufus D. Mason, vice-presidents; Dr. Joseph M. Aikin, secretary; Dr. Millard Langfeldt, treasurer, and Drs. Harry M. McClanahan, Benjamin F. Crummer and Andrew B. Somers, board of censors.

The York County (Maine) Medical Society met at Biddeford, January 10, and elected the following officers: Dr. Ambrose H. Weeks, Bar Mills, president; Drs. Henry I. Durgin, South Eliot, and Charles W. Blagden, Sanford, vice-presidents; Dr. Lawrence E. Willard, Saco, secretary, and Dr. J. Starr Barker, Kennebunk, treasurer.

The Kalamazoo (Mich.) Academy of Medicine met in annual session January 11. Dr. Herman H. Schaberg was elected president; Dr. Charles H. McKain, Vicksburg, first vice-president; Dr. Orrin F. Burroughs, Galesburg, second vice-president; Dr. Herman Ostrander, Kalamazoo, secretary, and Dr. Edwin H. Van Densen, librarian.

The Doctors' Club met at Newark, N. J., January 11, and elected the following officers: Dr. Katherine Porter, Orange, president; Dr. Ella Palmer, Jersey City, vice-president; Dr. Isabel M. Geddes, Newark [illegible] retary; Dr. Mary D. Hussey, East Orange, [illegible], and Dr. Augusta M. Madison, Newark, treasurer.

The Marion County (Ind.) Medical Society held its annual meeting in Indianapolis, January 7, and elected the following officers: Dr. Lehman H. Dunning, president; Dr. George H. F. House, vice-president; Dr. Theodore Potter, secretary; Dr. Fred L. Pettijohn, assistant secretary, and Dr. Simon P. Scherer. treasurer, all of Indianapolis.

The Montgomery County (Pa.) Medical Society, at its meeting January 10, elected the following officers: Dr. Percy M. Corson, Plymouth Meeting, president; Drs. George M. Stiles, Conshohocken, and J. Newton Hunsberger, Skippack, vice-presidents; Dr. Harry H. Whitcomb, Norristown, secretary, and Dr. S. Nelson Wiley, Norristown, treasurer.

The Philadelphia Medical Club held its annual meeting January 11 and elected the following officers: Dr. Edward L. Duer, president; Drs. John B. Deaver, Philadelphia, and Edward Marvel, Atlantic City, N. J., vice-presidents; Dr. Guy Hinsdale, secretary; Dr. F. Savary Pearce, treasurer, and Dr. James M. Anders, member of the board of governors.

The Schuylkill County (Pa.) Medical Society held its meeting in Pottsville, January 8, and elected the following officers: Dr. Alexander L. Gillan, Pottsville, president; Dr. Joseph P. Morris, St. Clair, vice-president; Dr. George W. Farquhar, Pottsville, secretary; Dr. David Taggart, Frackville, treasurer, and Dr. J. Spencer Callen, Shenandoah, censor.

The Madison County (Ala.) Medical Society discussed the smallpox situation at its meeting, January 8, at Huntsville, and elected the following officers: Dr. James L. Darwin, Huntsville, president; Dr. William D. Pettus, Rap, vice-president; Dr. Edgar Rand, Leighton, secretary and treasurer, and Dr. William C. Wheeler, Huntsville, county health officer.

The Georgia Medical Society, of Savannah, elected the following officers at its annual meeting, January 8: Dr. Thomas P. Waring, president; Dr. John A. Crowther, vice-president; Dr. Charles B. Lanneau, recording secretary; Dr. Arthur A. Morrisson, corresponding secretary; Dr. James G. Van Marter, Jr., librarian, and Dr. John S. Hawkins, treasurer.

The Androscoggin County (Maine) Medical Association met January 8 at Lewiston and elected Dr. Oliver A. Sprague, Turner, president; Drs. Edgar F. Conant and E. A. McCollister, Lewiston, vice-presidents; Dr. Richard R. Ricker, treasurer; Dr. Anson A. Cobb, Auburn, recording secretary, and Dr. Benjamin E. W. Cushman, Auburn, corresponding secretary.

The Orange Mountain (N. J.) Medical Society held its annual meeting at Montclair, January 4, and elected the following officers: Dr. Wellington Campbell, Short Hills, president; Dr. Francis J. E. Tetrault, Orange, vice-president; Dr. Richard D. Freeman, South Orange, secretary; Dr. Carl Buttner, Orange, treasurer, and Dr. Henry A. Pulsford, South Orange, reporter.

Chicago Academy of Medicine.

Regular Meeting held Dec. 14, 1900.

Dr. William A. Evans in the chair.

The topic for discussion was "Pregnancy," which was considered from various standpoints.

PHYSIOLOGIC AND FOLK-LORE ASPECTS OF PREGNANCY.

Dr. H. C. B. Alexander said that the most important phase of the physiology of pregnancy proper coming under the domain of the topic assigned is that which relates to the physiologic increase of woman's functions during pregnancy, and that which pertains to the resultant perturbations of the organs leading to autointoxications. The pregnant woman has regained in part the child's power of cell reproduction without the child's power of eliminating the waste consequent on cell reproduction. To increase the first, without decreasing the mother's future strength after childbirth, and to decrease the second, without affecting the first, are the two problems presented to the obstetrician by the disturbances of woman's physiologic equilibrium from pregnancy.

THE MUTUAL INFLUENCES OF PREGNANCY AND THE INFECTIOUS AND CONSTITUTIONAL DISEASE.

Dr. Robert B. Preble discussed this subject, and said it is usually considered from three standpoints, the influence of pregnancy upon the disease, the influence of the disease upon pregnancy, and the influence of the disease upon the fetus. The last aspect is the only one about which we have new information, for it is only recently that any attention has been given to this view of the question. Feré for some time has been making a series of interesting studies upon the influence of various agents on the chick embryo. He has exposed the egg in the incubator to alcohol, ether, tobacco and various other toxic bodies, including a variety of the bacterial toxins. In this way various monstrosities have resulted similar to those obtained by shaking the incubating eggs. It seems likely that these injurious agents and the various infections and intoxications, when they act upon the embryo before the differentiation of the various organs lead to malformations, and when they act after the organs are defined, their effects are similar to those experienced in post-fetal life. For example, malformation of the heart will result from injurious influences early in fetal life and fetal endocarditis and from similar influences felt later in uterine life. None of the infectious diseases is much altered by a coincident pregnancy. The only possible exceptions to this statement are those diseases which rapidly produce anemia, such as acute articular rheumatism, malaria, etc. The addition of such anemia to that of the pregnancy is markedly injurious. Another possible exception is that of acute yellow atrophy. This disease, undoubtedly an infectious one, is considerably more frequent in pregnancy and the puerperium than under other circumstances. Chlorotic women are usually sterile, but if they conceive, the anemia is intensified by the pregnancy. Women who, as young girls, have been chlorotic, often suffer a relapse during pregnancy. Pernicious anemia is made worse by pregnancy, but leukemia is not materially influenced. All of the acute and chronic infectious diseases have an injurious influence upon pregnancy and the fetus, often causing an abortion. With the exception of the variola, these diseases are usually no worse when combined with pregnancy than under ordinary circumstances, but the summation of the disease and a resultant abortion are bad. Variola, which occurs somewhat more frequently during the second half of pregnancy, is often of the severer form. Abortion occurs in about 50 per cent. of the cases; the severer the variola, the more certain the abortion. Pregnant women bear vaccination well, but the vaccination does not protect the fetus. According to Sedgwick, a fetus may have an intrauterine variola, or be born with the eruption without the mother having the disease. What is more probable is that the mother has had a variola without eruption. Scarlatina is an uncommon complication of pregnancy. Olshausen finds but seven cases. If severe, it excites abortion. Measles is somewhat more common than scarlet fever. Underhill has collected fifteen cases. In five of seven cases, occurring early in pregnancy, abortion occurred. All of seven cases in the last month of pregnancy miscarried early in the disease. Pregnant women show a certain degree of immunity toward typhoid fever, and this immunity increases in the second half of pregnancy, but the speaker has found no evidence bearing upon the correctness of this statement. When the disease occurs it causes abortion in considerably more than one-half of the cases. The maternal mortality from typhoid is somewhat higher than the average mortality, being 17 per cent. of 183 cases. Malaria often causes abortion, particularly in the second half of pregnancy; according to Goth, 41 per cent.; Weatherley, 46 per cent. The combination of the anemia of pregnancy with the hematolysis of malaria is particularly bad. In pneumonia the more advanced the pregnancy the more inevitable its interruption, and it is only when the miscarriage occurs during the ninth and tenth months that the fetus has a good chance. Cases treated expectantly give a mortality of 14.3 per cent.; those in whom abortion is induced give a mortality of 71.9 per cent. Influenza, during epidemics, is often the cause of abortion; the more severe the influenza, the more inevitable the abortion. It was formerly stated that tuberculosis became quiescent during pregnancy. The opposite is true. The more advanced the tuberculosis, the more injurious the pregnancy. With advanced tuberculosis abortions are common, and if the child is born alive it is a weakling. According to Grisolle, 38 per cent. of children of phthisical women die, and about one-fourth of these are stillborn. Actual transference of the tuberculosis, i. e., an intrauterine tuberculosis, while not unknown, is decidedly rare.

TOXIC HABIT AND TOXIC OCCUPATION ASPECTS OF PREGNANCY.

Dr. Charles S. Bacon said that when abortion is caused it may be due to the toxic substance acting injuriously upon the uterus, or it destroys the child and reflexly acts upon the uterus. If the poison directly affects the uterus it may affect the uterine muscle, causing contraction, or it may interfere with the circulation. A poisonous substance taken habitually, voluntarily, or accidentally, may affect the uterus. The basis of scientific knowledge on this subject was established by Gusserow a number of years ago, and since then confirmed by a number of other experimenters, who have shown that substances pass from the mother into the fetus through the placenta. Morphin undoubtedly passes through the placenta, but it does not follow that this drug affects the fetus as it would a born child. Strychnin, injected into the fetus while it is still in the uterus, in large doses, causes convulsions in the mother and perhaps death, but does not cause convulsions in the fetus. The fetus lives for some time after the death of the mother. Alcohol is commonly supposed to have some effect on pregnancy, but there are no conclusive proofs that taken in fairly moderate quantities it causes abortion. Experiments have conclusively established the fact that alcohol taken in moderate doses is not excreted by the breast, and only when taken in large quantities is it found in the milk. It is sometimes said that morphin causes abortion. Whether it does so by its effect on the uterus, or by affecting the child, is not definitely established, nor has it been absolutely proved that morphin does cause abortion. Another question is as to the effect of morphin on the milk when it is given to pregnant women. The excretion of morphin, or of any of the alkaloids of opium by the milk, has been claimed by some, but it has not been definitely established. That the fetus is affected in its structure and functions of various organs of the body by morphin much in the same way that it is affected by alcohol, is extremely probable. Workers in tobacco factories are apt to abort. About twenty years ago investigations were made by the French government on this subject, several hundred cases were collected and classified, which showed that no definite conclusions could be drawn. Chronic lead-poisoning is frequently the cause of abortion, but whether the abortion is produced by the action of lead on the uterus, by its action upon the fetus, or upon the mother, is an open question. It seems probable that lead acts upon the mother rather than upon the fetus, because the action of lead upon the unstriped muscular fibers of the intestine is well known, and it is probable that it may act upon the uterine muscles in the same way and cause uterine colic in the same manner that it causes bowel colic.

VENEREAL AND DERMIC ASPECTS OF PREGNANCY.

Dr. William L. Baum stated that gonorrhea very rarely interferes with the progress of pregnancy. In a number of cases the gonorrheal process is present shortly before the birth of the child, and it seems to exert very little, if any, influence upon pregnancy. Gonorrhea may influence pregnancy in this way, that a long-continued infection, or frequent reinfections as a consequence of endometritis, salpingitis, etc., may produce a disturbance during pregnancy. As to syphilis, it is the constitutional intoxication which plays an important rôle in subsequent pregnancies. It is known that in the majority of instances, particularly in untreated cases of the malignant forms of syphilis which occur in pregnant women, the women abort. The child, if carried to full term, may be syphilitic at birth, or manifest syphilitic symptoms thereafter.

As to the skin manifestations in pregnancy, he considered the effect of the skin disease upon the course of pregnancy, and the etiologic factor in pregnancy which causes certain dermic manifestations to take place. Frequent attacks of pruritus without any apparent skin lesions may be noted. During pregnancy there may be multiple types of erythema and a great many true neuroses of the skin. Skin lesions of the pigmented type, such as chloasma, may be brought about by other conditions than pregnancy. There is very little literature on the subject of the exanthemata having any particular effect upon the progress of pregnancy, except those of the contagious type.

RENAL ASPECTS OF PREGNANCY.

Dr. Charles E. Paddock discussed this phase of the subject. It may be only one of the numerous modifications produced by the economy of gestation, and while the diagnosis is not always easy, the treatment will, as a rule, determine it. It is claimed by Winckel that 2 per cent. of women who were healthy before pregnancy have albumin in the urine during pregnancy, and it is further claimed that 6 per cent. of all pregnant women have albuminuria. Pregnancy in the majority of women is not a physiological process, and the sooner this is understood, the better it will be for the mother and child. The changes going on in the economy of the woman call for greater demands upon the heart, liver, kidneys, etc., and any interference with the action of one of these organs acts disastrously upon the others. There would be fewer cases of albuminuria and eclampsia if hygienic rules were adhered to. If albumin be present during the first few months of pregnancy, rest in bed and a milk diet will usually be all the treatment that is necessary. If, however, there are other symptoms showing a beginning intoxication, more heroic treatment will be necessary. Should the urine show no change under this treatment, the emptying of the uterus is imperative. Under ordinary circumstances the eclamptic attack must be controlled by chloroform and chloral, and labor allowed to go on. The attack, as a rule, induces labor. Olshausen and Veit advocate the use of morphin. Morphin in the speaker's experience has been unsatisfactory. He feels much safer with chloroform and chloral, and believes the use of morphin in eclampsia has influenced unfavorably the mortality.

From the present state of knowledge concerning albuminuria and eclampsia, the author concludes that the etiology and pathology are unknown; that the kidney shows the most constant lesion, but may be entirely healthy; that the majority of the cases are acute exacerbations of a chronic nephritis, and that the principal treatment is prophylactic.

NEUROLOGICAL ASPECTS OF PREGNANCY.

Dr. Daniel R. Brower referred to nausea and vomiting and uterine pain as being among the nervous phenomena of pregnancy. The remedies most useful to control vomiting are those that appeal to the nervous system, namely, tonics and sedatives. Nausea and pain, in the early months of pregnancy, are noted mostly in the neurasthenic type of women. Chorea of pregnancy is a serious neurological condition. It is to be combated by the same general methods that are employed in ordinary chorea. He pins his faith in the treatment of chorea to some one of the preparations of arsenic, administered in heroic doses.

Multiple neuritis, or the neuritis of pregnancy, is rare, and is doubtless, when it occurs, the product of auto-intoxication. Hysteria develops from the pregnant state, but the basis for it is laid in the previous history of the individual, pregnancy being simply one of the additional factors.

THE PSYCHIATRIC ASPECTS OF PREGNANCY.

Dr. W. G. Stearns, in explaining the comparative rarity of insanity in pregnancy, said that it must be recognized that the parturient state is natural; that woman was born to that end, and that her system has been prepared for it, and is consequently better fitted to withstand its depletions than the other strains placed upon her by unfavorable or vicious external conditions. The psychosis which most commonly develops during gestation is melancholia. Ushered in by a gradually deepening depression with timidity and vague forebodings, later profound depression, undefined fear and despair, suicidal tendencies, refusal of food, and sometimes positive stupor become the most prominent mental symptoms, but can not be distinguished from those found in melancholia otherwise produced. Puerperal insanity is more frequent than either the insanity of pregnancy or lactation. While the psychoses developing in pregnancy and during lactation are chiefly melancholias, about two-thirds of the cases occurring during the puerperium are manias. Seventy-five to 80 per cent. of women recover in puerperal insanity in from two to nine months, but occasionally recoveries are delayed for from two to three years. About 10 per cent. die, and the remainder become chronically insane. Lactational insanity may be any form of derangement, but is oftener melancholia from exhaustion, particularly if another pregnancy or the return of the menses combine to deplete the nutritional supply of the nervous system. Hallucinations are common. The treatment and management of the psychoses occurring in the course of childbirth should differ in no essential manner from that of mental disease occurring at other times, with the exception that much more can be expected of prophylactic treatment.

OPHTHALMOLOGICAL ASPECTS OF PREGNANCY.

Dr. Casey A. Wood pointed out that the most important condition for which the ophthalmologist is consulted, is difficulty of accommodation, namely, difficulty in reading, in writing, in doing near work generally. Muscular conditions in the eye are different during pregnancy from those before and after it, and they do not differ from muscular difficulties observed in the body elsewhere. A primipara not infrequently requires the aid of glasses in reading or doing near work, but after pregnancy has been completed she can dispense with them. Pigmentation of the eyelids is not infrequently seen in pregnancy, which is merely a part of the general pigmentation. Cases of well-marked blindness, and even of complete blindness, have been observed and reported as one of the outcomes of gestation. Violent and long-continued vomiting produces small hemorrhages into parts of the eye, and sometimes serious results follow. Detachment of the retina is not a very uncommon condition in pregnancy. Retinitis albuminurica frequently accompanies pregnancy, but the disease of the retina shows itself in a more favorable form in pregnancy than it does in the ordinary forms of Bright's disease. The prognosis is not as grave in pregnancy from albuminuric retinitis as it is in chronic Bright's disease, although the conditions are about the same. Temporary amblyopia of uremia, with or without albuminuric retinitis, was referred to. Occasionally a patient who is pregnant, whether albuminuria be recognized or not, has temporary or even complete blindness, which may last from a few hours to a few days. These patients almost invariably get well. Nothing pathological can be seen in the fundus by the ophthalmoscope.

LARYNGOLOGICAL ASPECTS OF PREGNANCY.

Dr. Edward T. Dickerman referred to the influence of pathologic conditions of the upper respiratory tract upon pregnancy. In the first four months of pregnancy, especially in women of a neurotic temperament, nasal obstruction is observed, or there is a turgescence of the erectile tissue in the nose. This condition gradually subsides toward the sixth or seventh month, when nasal breathing is again restored. Late in pregnancy the tones of the voice may be affected. The upper tone limit may be lowered. Many professional singers fear pregnancy on account of losing their voice. During pregnancy there is a lowering of the voice due to interference with free chest expansion. Afterward there is a general relaxed states of the abdominal muscles which, until they resume their normal tonicity, may influence voice production, but pregnancy should have no permanent influence upon the voice. Tertiary syphilitic lesions of the larynx and of the pharynx are almost invariably retarded during pregnancy, and they remain practically in a dormant state for months after parturition has taken place, when they take on renewed activity and the tissues rapidly break down.

THE TEETH IN PREGNANCY.

Dr. Eugene S. Talbot said that during pregnancy women are subject to more or less discomfort, annoyance and inconvenience from the teeth. The disturbance may vary from slight uneasiness to the severest form of odontalgia involving one or several teeth. Decay not only takes place in new localities, but rapid disintegration about new fillings is very common. The teeth are so sensitive and soft they can be cut like chalk. The decay creates the appearance of horn or cartilage, showing that the tooth is deprived of its lime salts by a process similar to osteomalacia in bone. When children are born at frequent intervals, especially if complications arise, the teeth are frequently completely destroyed. Interstitial gingivitis is likewise a common condition of the jaws and gums during pregnancy. Mouths healthy before pregnancy become diseased. So far as the alveolar process is concerned, there is a different etiological factor. Much stress is laid upon the normal physiological nature of pregnancy and childbirth. The changes which occur in nutrition, secretion and excretion, however, indicate a new factor, which, under Virchow's definition, must be pathologic, albeit not nosologic. One of the most marked changes is a perverted function of the excretory organs. The effete matter is not eliminated and auto-intoxication results. The alveolar process is a transitory structure. It is simply developed for the purpose of holding the teeth; when these are lost, the process absorbs. The effect of auto-intoxication upon the alveolar process is to produce interstitial gingivitis, halisteresis, osteomalacia, Volkmann's perforating canal absorption, and endarteritis obliterans. The indications are inflammation of the gums, absorption of the process, leaving the necks of the teeth quite exposed. The teeth later loosen and drop out. The teeth of pregnant women should be put into a healthy condition as soon as possible. Dental operations should only be done as a necessity. After the teeth have been put in order the physician should insist upon perfect cleanliness of the mouth and teeth.

Dr. James G. Kiernan, in discussion, took issue with Dr. Bacon. He could not see, with regard to the question of the passage of morphin through the placenta and mammary gland, why more evidence is needed than the researches of Loewenstein, Potter, Bureau, and others, who have found morphin in the mammary gland and in the placenta. With regard to tobacco studies, thirty years ago, or a little over, boodle investigations were made by the French government in connection with the government monopoly of tobacco. These, like the English opium investigations made in India, were intended to be as little derogatory of tobacco as the English investigations were of opium. Etienne, in 1897, made a careful investigation of the women who work in the tobacco factories. Corroborative results were noted as to findings in other European tobacco factories, as well as in some of the tobacco factories in this country. Furthermore, observations prove that the fluids discharged at delivery contain nicotine. As to the influence of lead poisoning on the offspring of the Staffordshire potters, he could speak strongly. He has had cases of big-headed idiots, in one of whom the brain at the age of 21 weighed 68 ounces. The barren ependyma formation lining the ventricles, replacing the old hydrocephalus, as it did in the case of Cuvier, was six times as thick as it should be. Strictly speaking, however, so-called hypertrophy of the brain in macrocephalic idiots is connective-tissue hypertrophy, not active functionating hypertrophy of nerve cells.

Cincinnati Academy of Medicine.

Meeting, Jan. 7, 1900.

President Dr. C. L. Bonifield in the chair.

GALLSTONES.

Dr. B. Merrill Ricketts reported cases, also presenting specimens. Case 1. Male, aged 45 years, had suffered from severe attacks of colic for twenty years. Four years ago he passed some 40 octagonal stones about the size of a pea. Cholecystotomy was made Dec. 30, 1900. The gall-bladder was found bilocular and closely adherent to the stomach and duodenum; all adhesions had to be separated before the gall-bladder could be brought into the abdominal incision. It was then deemed necessary to incise each cyst, and from the lower cyst was removed 10 stones, from the upper or fundus, 77. These stones were all about the size of a pea, were octagonal, and were extremely highly polished. Before concluding the operation the septum dividing the gall-bladder into two compartments was torn away, thus forming one cavity. Since the operation the temperature has never been above 99.2: there has been no pain or icterus, and his recovery seems assured. Case 2. Male, 39 years old, with a history of icterus and of colic extending over many years. Cholecystotomy was made Dec. 13, 1900. On opening the gall-bladder, there were found 15 stones and an equal number were removed on the fifth day. An evacuation of the wound on the fifteenth day contained many small fragments of biliary concretions, but subsequent dressings have failed to show any and the biliary tract is in all probability free from these concretions. The patient made an uninterrupted recovery and the wound is now entirely closed. Case 3. Male, 39 years of age, with a history of having suffered from occasional attacks of gall-stone colic for several years. Cholecystotomy was performed about Dec. 1, 1900. On opening the gall-bladder, about five ounces of a clear fluid apparently containing pus, escaped. He had not been able to find a stone either by the finger or the sound in either the gall-bladder or the common duct. Bile flowed freely until about the fifth day, when he was seized with a severe paroxysm of pain and the amount of bile was doubled. A stone was suspected, especially as he would have occasional attacks of pain. He returned home on the 18th day, only to have a severe attack of colic within 24 hours. He returned to the hospital, and on examining the dressings there were found several broken fragments of a smooth stone without facets. The wound has been kept open in the hope that other fragments, the presence of which are suspected on account of the occasional attacks of pain, may be discharged. In case this does not happen it is more than probable that another operation may become necessary at some future time. The essayist believed that the escaped stone had been present in a dilated hepatic duct. As to the causes of the fracture of the stone or stones, "the probabilities are that the absorption of oxygen, the changing of the fluid discharging from alkaline to acid, or the contraction of the tissues of the biliary tract, one or all, are the causes for the breaking into fragments of the stone or stones."

SPINAL COCAINIZATION.

Dr. H. J. Whitacre reported three cases. Case 1. Double complete fistula in ano. Patient a male, aged 45, very dissipated as regards his habits, presented himself at Christ's Hospital for treatment. On physical examination there was found consolidation, probably tubercular, in the upper lobes of both lungs, a mitral regurgitant murmur, and the kidneys chronically diseased; in addition he gave a history of having taken many forms of alcohol cure during the last ten years, and admitted a recent protracted spree of about four weeks' duration. Fifteen minims of a 2 per cent. cocain solution—put up in sterile pearls—were injected into the spinal canal between the fourth and fifth lumbar vertebræ. The patient said at the end of ten minutes that there was some numbness in his feet, but the anesthesia did not extend higher. Even at the end of 45 minutes there was no further progress. Suddenly he stated that there was no sensation in the buttocks, and examination revealed this to be the case, as also in the perineal region, though the lower extremities never lost sensitiveness. Anesthesia extended as high as the umbilicus. The operation was now performed, painlessly, in twenty minutes. Even when the operator inserted his finger some four inches into the rectum and delivered the grooved director that had emerged at this point, the patient complained only of a dragging sensation. There were no toxic manifestations. On the day following the operation, he complained of an attack of sciatica, which he himself assigns to the peculiar—lithotomy—position he had to assume during the operation, as he has previously had many such attacks. Nothing else of an unfavorable nature appeared. Case 2. A male, 82 years of age, with a history of prostatic enlargement covering a period of many years. During the last two years he has suffered from attacks of acute cystitis or of retention, so that fully eighteen months of this time has been spent in hospital wards at various intervals. He was able to catheterize himself fairly well, until he one day attempted to improve matters by forcing the meatus and urethra with a hickory stick; since that time an experienced physician has had the greatest difficulty in introducing a catheter. His advanced age, arteriosclerosis, and damaged kidneys would have made the giving of a general anesthetic an extremely hazardous matter. Eighteen minims of the 2 per cent. solution were used for the injection. Vomiting occurred in about three minutes and he complained of weakness. His face was pale, but his pulse showed no alteration. In ten minutes, operation was begun; it consisted of a perineal section, external urethrotomy, and removal of the right prostatic lobe. This was all done without pain, without evidence of shock, and with no failure on the part of any of the vital functions. Anesthesia continued over an hour. Recovery was uninterrupted. Case 3. Male, 17 years of age, with a history of osteomyelitis of the femur of six years' duration. At the time of the injection the patient made a sudden movement and anesthesia not ensuing in over an hour, essayist is certain that this movement threw the needle out of the spinal canal and the fluid was injected outside the dura. He was certain that the second injection made two days later entered the dura, but no anesthesia following in over an hour, ether was given. The only untoward symptoms following the injection were a headache twenty-four hours after and a slight rise of temperature. His method of giving the injection in these cases was that of Tuffier, and he endeavored to maintain the rigid asepsis of a major operation. The essayist then gave a history of the operation and reports as to mortality up to date. He also stated that in his opinion the operation had best not be performed in nervous women and children. He did not think that the method would be used higher in the cord. As regards the advantages to be derived he said that operations have often to be made on patients the victims of severe pulmonic, cardiac, or renal disease, in which patients a general anesthetic would be dangerous to the highest degree.

RAYNAUD'S DISEASE.

DRS. A. RAVOGLI and M. L. HEIDINGSFELD presented a patient afflicted with Raynaud's disease; a male, aged 24, of German birth, duration of his disease ten years. The fingers of both hands were affected about equally. They were enlarged to about twice their normal size, and were chronically edematous; they were very cold to the touch and of a bluish-red color; a few bullæ were present on the phalanges of several fingers, and at the digital extremities of several of the metacarpal bones; these bullæ had a tendency to necrosis; there was diminished sensation to heat and cold. There was no hyperesthesia or anesthesia; no periodicity; involvement of the fingers alone: no direct or predisposing cause such as trauma or exposure to cold. On account of these facts the diagnosis must be held sub judice, with the possibility of the case being a vasomotor or trophoneurotic change, such as chronically cold hands, erythromelalgia, or angioneurotic edema. Some improvement has been noticed under intestinal antiseptic treatment.

DR. B. F. LYLE reported a case of Raynaud's disease that had died at the branch hospital for consumptives. He had been sent from the city hospital on account of areas of dulness involving both apices. On post-mortem examination there was found a fibroid condition of the apices, a general edema of the lungs—the direct cause of death—a fatty liver, and as was afterward shown by microscopic examination, a sclerosis of the posterior and lateral columns of the spinal cord. The man's mental condition was such that no satisfactory history could be obtained at the time he entered the branch. The gangrene had first attacked the left great toe, and had gradually involved, symmetrically, a considerable portion of both legs. The upper lip and the tip of the nose had also suffered.

DR. F. W. LANGDON, who had also examined the case, agreed in the diagnosis, and stated that at the time of the examination the patient's condition was such that nothing satisfactory could be elicited.

DR. J. E. GRIEWE made a detailed report as to the pathological changes in the spinal cord, and was inclined to the view that they were not causal so far as Raynaud's disease was concerned, not casual, but a part of a general pathologic change, of which the gangrene and the symmetrical fibroid changes in the lungs were other and coincident phases.

DR. A. RAVOGLI stated that the patient was in the dermatological ward of the Cincinnati Hospital, and on his service several months before he was transferred to the branch. At that time his mental condition was good and he gave a well-marked history of local asphyxia and of periodicity covering a period of some six or seven years previous to the onset of the gangrene. He was inclined to the opinion that it was a well-marked case of Raynaud's disease.

Philadelphia Pediatric Society.

Meeting Dec. 11, 1900.

President Dr. Alfred Stengel, in the chair.

TRANSPLANTATION OF PEDICLED FLAPS.

DRS. C. H. FRAZIER and A. L. NEWHALL reported a case of flaps transplanted from buttock to hand, with exhibition of patient, a colored boy aged 3 years, who had two years ago fallen against a hot stove, striking on the palm of the hand. A severe burn resulted, followed by cicatrization and contracture. The operation consisted in making two parallel incisions on right buttock, after which the scar tissue on the hand was removed. The sides of the flap on the buttock were stitched to the sides of the hand; a few days later the upper and afterward the lower edges of the flaps were dissected loose and stitched in a similar manner. The parts were kept immobilized, good union has resulted, and the hand and fingers are almost normally useful.

SPASTIC PARAPLEGIA.

DR. C. F. JUDSON reported a case following traumatism in a child 5 years old. The father had died of diabetes. There had been no history of paralysis on side of father or mother, except an aunt, who had suffered from late hemiplegia. At 2½ years it had suffered from typhoid and later from chickenpox. The present illness dates from about Jan. 7, 1900. The onset was apparently sudden and marked by a period of unconsciousness lasting ten minutes. About the fifth week he began to manifest weakness in the legs, and gait became awkward. Later the gait became typically spastic and he could not walk. The muscle sense was good, as was also co-ordination. Sensation to pain was slightly reduced; eyeground was normal. There was no involvement of sphincter nor evidences of rickets. After a course of warm baths and rest in bed ankle-clonus, which had been present, now disappeared, and the child began to improve, and at this time is able to walk, but with a distinctly spastic gait. There is no evidence of Pott's disease.

INFANTILE PALSY.

DR. ALFRED STENGEL reported several cases accompanied by more or less wasting. He believes that the condition was more prevalent in the city than usual, an opinion in which several speakers concurred.

DR. J. P. CROZER GRIFFITH exhibited a case of nodding spasm. The patient was a colored child about 1 year old, whose condition was manifested by continual nodding backward and forward, but at times a rotary movement would occur. The child was not distinctly rachitic.

DR. A. A. ESHNER had seen a good many of these cases at the Orthopedic Hospital which had been associated with rickets.

DR. D. J. M. MILLER had several years ago treated three similar cases with bromids and out-door life with great benefit.

Meeting Jan. 8, 1901.

President Dr. Alfred Stengel, in the chair.

SEVERE ANEMIA WITH LEUCOCYTOSIS.

DR. S. M. HAMIL reported a case of severe anemia with leucocytosis in an infant of six months. This child had been breast-fed. It presented a yellowish color. At the first examination it was found that the liver and spleen were both enlarged. A murmur could be detected over cardiac area and vessels of the neck. The blood examination showed 3,000,000 red corpuscles and the leucocytes ranged from 23,000 to 29,000. Nucleated red-cells were present, as was poikilocytosis. The lymphocytes formed about 67 per cent. There were no evidences of rickets, scurvy, nor tuberculosis. The speaker regards the case as being a border line, one between leukemia and pernicious anemia.

LEUKEMIA IN AN INFANT.

DRS. J. A. SCOTT and H. M. FISHER reported a case in which the red cells had numbered 3,360,000 reds, and the leucocytes 36,500. The polymorphonuclears had been 25 per cent., eosinophiles 8 per cent., and the hemoglobin 30 per cent. A considerable number of myelocytes had been present, but were now diminishing, as were the nucleated red cells. The child lately had suffered from an attack of diarrhea, the stools numbering ten or twelve each day. The spleen had diminished considerably in size. There had never been any hemorrhage from the mucous membranes. By a mistake this child had been taking large doses of tincture of nux vomica, which had seemed of benefit and the medicine had been continued.

MALFORMATION OF THE BOWEL.

DR. E. E. GRAHAM exhibited a specimen of malformation of the bowel. This child had been born at term and seemed normal. During the first twenty-four hours the child refused to take the breast, and on the following day an unsuccessful effort was made to have it nurse. Up to this time there had been no bowel movement, but vomiting had occurred. Twelve hours subsequently the abdomen became distended. At this time he suspected some obstruction of the bowel and made a rectal examination, but the obstruction could not be felt. Later the abdominal distention become more pronounced and an operation was decided upon, which was done under the influence of local anesthesia, with success, the patient manifesting no symptoms of pain. On making an incision a point of obstruction was found in the distal end of the colon which terminated in a cul-de-sac and was adherent to the sacrum. The child rallied from the operation only slightly, and died a few hours later.

GYROSPASM OF HEAD, WITH NYSTAGMUS.

Dr. D. J. M. Miller presented a case. The child had been artificially fed from birth. Last summer it had suffered from an attack of colitis. The head movements began in May last and have continued since that time, but in September were not so pronounced. Two weeks ago there was lateral rhythmic movements, and on holding the head still, nystagmus would develop. Examination of the eye-ground proved negative. In these cases a history of acute illness may usually be determined.

Dr. Frank White stated that he had at present under observation of a case of a similar nature to the one presented, but more marked in character.

CONGENITAL SARCOMA OF LIVER AND SUPRARENAL CAPSULE.

Dr. William Pepper read a paper on and presented specimen of this tumor. The father of the child had at one time suffered from insanity. The mother had six other children, all seemingly healthy. There was no history of syphilis. The patient had been born at the sixth month of gestation. A few weeks after birth a tumor could be outlined in the abdominal region, the latter region being bulging in character. The mass filled up the right iliac region and extended slightly to the left of the umbilicus, where a rather sharp border could be felt. Flatness was elicited over the entire area. The child died when three months old. At the autopsy it was found that the entire abdominal region was filled up by the liver and spleen. The capsule of the liver had a marbled appearance with hemorrhagic foci. A few enlarged lymphatic glands were found in the abdominal region. The growth had been one of typical lymphosarcoma. The speaker had made a thorough review of the literature on this subject. The facts seemed to indicate that the growth is essentially of congenital origin. In the majority of instances there is a history of rapidly growing tumor coming on a few weeks subsequent to birth, and without pain. A history of syphilis is generally not present. In certain cases the sarcoma might be round-celled in type. One writer had thought the primary seat of these growths was located in the liver, others that it was in the right suprarenal. This case seemed to originate in the latter locality.

Dr. J. A. Scott thought that one of the marked features of the case was the profound involvement of the suprarenal, without evidences of pigmentation.

Dr. Pepper, in closing, stated that of 41 cases reported only slight pigmentation had been present in 3 instances.

Dr. Alfred Stengel then delivered the annual address.

San Francisco County Medical Society.

Regular Meeting Dec. 11, 1900.

President Dr. Geo. H. Evans in the chair.

SOME OF THE RARER COMPLICATIONS OF GONORRHEA.

Dr. M. Krotoszyner referred to the ravages of the gonococcus on the posterior urethra, bladder, ureters, and pelvis of the kidney in males, and the ascending gonorrheal infections in women, generally ending in a complete destruction of the uterine adnexa, and called particular attention to the nervous complications of this disease. He had personally seen many cases of very severe hypochondriasis caused by a chronic posterior urethritis, which in the majority of instances had been submitted to too much treatment. In his service in the French Hospital (genito-urinary) at least 60 or 70 per cent. of all his patients suffer with sexual neurasthenia. Besides these functional troubles, organic affections of the nervous system on the basis of gonorrheal infection had been reported, of which three forms seem to be most prevalent: 1, neuralgic affections caused by gonorrhea, especially gonorrheal sciatica: 2, gonorrheal muscular atrophy and atrophic paresis; and, 3, gonorrheal neuritis and myelitis.

He reported a recent case of the first form in which a man had been confined to bed for several weeks with excruciating pains along the course of the right sciatic nerve, and the history of a recent gonorrheal infection. The sciatica, however, did not abate until several weeks after the disappearance of the discharge. In speaking of the third form, he said the literature on gonorrheal myelitis is not so scanty as one may be led to assume. As far back as 1839 Stanley described a case of paraplegia of the lower extremities caused by gonorrhea. Since that time a number of cases have been reported by other authors. Moltschanoff was able to establish organic degenerative processes in the spinal column of animals inoculated with the toxins of gonococci, which produce a complex of symptoms similar to that of tabes. He thought that the connection of gonorrhea with nervous diseases seems to call for just as much attention and study on the part of the neurologist as that of syphilis and nervous affections. Another rare complication of gonorrhea that the author observed a few months ago was in the case of a young man of 23, under his care for a severe attack of gonorrheal urethritis, prostatitis, and epididymitis, who called his attention to an affection of the finger nails, which he had noticed for two or three weeks. There appeared a sharp demarcation between the matrix and body of the nails. The upper part of the nails showed a grayish discoloration and rugged edges. It seemed as if the body of the nails would soon fall off. There was no history of syphilis. The patient was referred to Dr. Douglass W. Montgomery, who also could not arrive at a satisfactory conclusion as to the etiology of this nail affection. The author observed the patient closely and noticed the absolute disappearance of his nail disease with the abatement of his gonorrheal affection. He said that it was a well-known fact that in weakened and tuberculous subjects gonorrhea is sometimes incurable; on the other hand gonorrheal infection may weaken the system to such an extent as to lessen the resistance to tuberculous infection, either of the general system or locally. He had recently seen a case of tuberculous vesiculitis and orchitis on the basis of a chronic posterior urethritis, and thought that gonorrhea would occupy a very important place as an etiologic factor in tuberculosis. This opens up a new field for observation and study, and many dark pathologic conditions now unexplainable as to their etiology may be cleared up by the knowledge that gonorrhea, heretofore considered a simple local affection, is in truth a constitutional disease, and that the gonococcus forms toxins which may invade all organs and tissues of the body, and produce as manifold and serious complications as those we are accustomed to observe in syphilis.

Dr. D. W. Montgomery said that on March 28, Dr. Krotoszyner sent him the patient referred to. "The man, 21 years of age, a cook by occupation, was suffering at the time from gonorrhea, but his general health was good. He told me that the affection of the nails began six or eight months previously; in that of the left middle finger; there was a great deal of pain, and the whole finger-tip was reddened, but there was no redness at the base of the nail. The nail of the left index finger was the next affected; at the start this was painful and the finger-tip was reddened. The subsequently affected fingers were neither red nor painful. The left thumb nail was the only one that fell off entirely. The toe-nails were not affected; there was no numbness nor anesthesia nor other nerve symptoms, nor was he troubled with cold hands or feet. The skin was in all other situations in good condition, white and normal. There were no symptoms whatever of psoriasis, and as previously mentioned, the patient had never suffered from syphilis. The hair and teeth were good. When I saw him, the nails of the left ring, middle, index, and the right thumb, were affected: the affected nails were white, and broken with uneven free edges. The nails had lifted under their free edge, and the process had worked backward, separating the nail from its nail bed. There was no advancing red border such as is seen in psoriasis, indicating the advancing edge of the disease. As Dr. Krotoszyner has said, I did not know what to attribute the disease to. There was no history of syphilis, there was no evidence of disease of the nerves, and there was no sufficient evidence of psoriasis. If this nail affection is to be attributed to gonorrhea; then it differs from the gonorrheal nail affections described by Vidal, Jeanselme and Stanislowsky, in there not being at the same time a corneal dermatitis."

GASTRIC CARCINOMA.

Dr. S. I. Harrison presented a carcinoma which he had removed Sept. 22, 1900, from a man 50 years of age. The man came from Nevada, where he had been treated for about three years for gastric catarrh. He came complaining of constant nausea and frequent vomiting—no blood—and discharging large quantities of mucus from the bowels. The tumor was situated under the outer margin of the left rectus muscle. It was quite movable, could be shoved up under the ribs or drawn down almost to the umbilicus, but always remained on the left side. Celiotomy was done with the assistance of Drs. E. E. Kelley and F. B. Carpenter. The incision was made through the left rectus muscle, and the tumor was found in the anterior wall of the stomach near the pylorus and had invaded a large area. Two fifths of the stomach, including the pylorus, was removed. The incision in the stomach was entirely closed by three rows of catgut sutures. An end-to-end anastomosis was then made between the duodenum and posterior wall of the stomach by means of a Murphy button. He rallied well from the effects of the operation, his temperature never exceeding 100.4 F., and on the fifth day feeding by the stomach was begun. At the end of two weeks he was able to sit up, and three weeks from the time of operation he left the hospital. The Murphy button had not been recovered. A careful search had been made, except on two or three occasions during his last week in the hospital, when he went to the toilet, contrary to orders.

When last seen he stated that he could eat and digest any kind of food without distress, and was gaining in weight at the rate of a pound a day. No X-ray search had been made for the button.

Chicago Surgical Society.

Regular Meeting Held Jan. 4, 1901.

Dr. Christian Fenger in the chair.

MORRISON OPERATION FOR LIVER CIRRHOSIS.

Dr. L. L. McArthur presented a patient upon whom he had performed the Morrison operation—operative establishment of collateral circulation. The man had been a hard drinker of distilled liquors for years, and had ultimately developed the characteristic hobnail liver. The result of the operation was excellent. He said that an excellent résumé of the literature on this subject could be found in a recent number of the *American Journal of the Medical Sciences*, by Fraser, who reports the fourteenth case. The operation should be done under cocain anesthesia, as recommended by Fraser.

Dr. M. L. Harris did a similar operation in February, 1900, on a man 54 years of age, who had been a very heavy drinker of whisky. The third week after the operation the patient left for home. Eight weeks thereafter he died suddenly. At the autopsy cerebral hemorrhage was found as the cause of death, the hemorrhage having taken place in the ventricles of the brain.

TWO CASES OF HIP-JOINT DISEASE TREATED BY THE PHELPS METHOD.

Dr. M. L. Harris presented these cases. The first was a boy, 7 years of age, who was admitted to the Children's Hospital, Aug. 10, 1900, and discharged Dec. 30. Patient was admitted in the usual condition, greatly emaciated, having hectic fever, pain, and the characteristic deformity of hip-joint trouble. There was a large abscess filling the left hip-joint and extending beneath the tensor vaginæ femoris muscle almost to the knee. He was operated on Aug. 29, the joint opened, and the tubercular focus, found on the upper surface of the neck and inner surface of the great trochanter, removed with curette. The joint was filled with pus and tubercular granulations, which were removed with curette. The abscess extending down the thigh was opened in the same way, and also posteriorly where an abscess had dissected backward. The joint was filled with carbolic acid—95 per cent.—and allowed to remain one minute, when it was removed and alcohol used. All the cavities were filled in the same manner, and washed out with alcohol and dried thoroughly with gauze. A large drainage-tube was used, and the wounds packed with gauze. A long anterior Thomas splint and plaster to fix the joint were used. Improvement was rapid; the cavities closed up, and the joint is now well.

The other patient, a boy of 4 years of age, was admitted to the hospital July 9, and operated on July 15. The case was essentially the same as the first one. The joint was opened, the tuberculous focus found on the upper surface of the neck extending into the joint, and was thoroughly removed with curette. The joint was filled with carbolic acid and washed with alcohol in the same manner as in the first case, a large drainage-tube being introduced, the joint packed, the wound dressed in the same manner, with Thomas splint, and the boy is now running around.

Dr. Harris mentioned three more cases in the hospital which he had treated in the manner described, but they had been operated on so recently that they were not well enough to be presented. In both of the cases presented almost complete motion in the joint was preserved.

Dr. Christian Fenger referred to the early operations that were made for disease of the hip-joint some fifteen or twenty years ago. He asked whether the Phelps method of treatment was equally satisfactory for primary synovial tuberculosis. The results in the two cases presented by Dr. Harris were more favorable than those from iodoform emulsion injections alone.

Dr. McArthur stated that the conservative surgeon should explore any sinuses or abscess cavities that may be associated with probable hip-joint disease, and see whether the tubercular focus lies in the fossa within the greater trochanter or whether it be a tuberculosis of the acetabulum, for in 2 or 3 per cent. of the cases the hip-joint may be spared if the diseased area be curetted and the joint not incised.

Dr. Harris answered the question of Dr. Fenger by saying that he had not used this treatment in any case of primary synovial tuberculosis. In five cases he had used it in primary hip-joint trouble. It is not the intention to dissect out the capsule in the Phelps method. The tubercular foci are removed by means of the curette, and the joint cavity filled with carbolic acid.

CONGENITAL ANGIOMA OF TONGUE.

Dr. Jacob Frank presented a case of congenital angioma of the tongue in a man, 71 years of age. The patient was shown to elicit opinions as to operative intervention.

Dr. Christian Fenger said that if an angioma of the tongue begins to grow, it should be removed immediately. He had operated on one such case, removing one half of the organ, and the patient is still living.

SURGERY OF THE BLOOD-VESSELS.

Dr. John B. Murphy read a paper in which he spoke of the surgery of the blood-vessels.

In the discussion Dr. Fenger said that the essayist had taken an original step forward in this work, it being an improvement over the invagination method practiced by him (Murphy) in 1897. Where suturing of the arteries can be done, invagination should not be undertaken. Suturing arteries is the easier method.

Dr. A. E. Halstead stated that Lambert was the first to resort to arterial suture, he having made a longitudinal suture of the carotid artery in 1762. Dr. Halstead mentioned a case in which, three weeks ago, he sutured an oblique wound of the first part of the axillary artery. The patient was a woman, 43 years of age, on whom he was operating for a recurrent carcinoma of the breast. The axillary artery was cut obliquely through two-thirds of its circumference while removing the tumor from its sheath. The hemorrhage was controlled by pressing the artery against the clavicle with the index finger of the left hand. Four interrupted catgut sutures were then passed through the two outer coats of the vessel, closing the wound perfectly. The radial pulse was immediately restored.

Dr. Arthur Dean Bevan considered suture of the arteries as being still in its experimental stage, and he regarded the old method of ligating an artery at two points, on either side of the injury, as the safer method.

Dr. Murphy admitted that the work was in its developmental, but not its experimental, stage. The clinical results favored some other means than ligation of arteries.

New York County Medical Association.

Stated Meeting, Dec. 17, 1900.

President Dr. Parker Syms in the chair.

RETENTION CYST OF THE LIVER.

Dr. William A. Shufelt presented this specimen, which had been removed by operation. There was no evidence of calculi in the cuts, and the gall-bladder was normal. He said that he had been able to find recorded only five cases of simple cyst of the liver. These had been, for the most part, sterile echinococcus cysts, but he had been led to regard his specimen as a retention cyst beause of the absence of echinococcus hooklets, the fact that the cyst had been found filled with bile, and because of its histological relations.

TUBE AND OVARY IN AN INGUINAL HERNIA.

Dr. Shufelt also presented this specimen, which had been removed by operation from a woman of 30, who had had for a long time an irreducible inguinal hernia. At the operation the sac of the hernia was found to contain a perfectly developed tube and ovary.

COFFEE AS A BEVERAGE: ITS DELETERIOUS EFFECTS ON THE NERVOUS SYSTEM.

Dr. William M. Leszynsky said that to indiscriminately condemn coffee as useless might shock the faith of multitudes. The purpose of the paper was to show that the ill effects of coffee were by no means uncommon. This statement was founded on a careful study of this subject for the past ten years. Roasted coffee contains caffein and caffeone. We all realize the excellence of coffee as a medicinal agent. From 1892 till 1896 the average importation of coffee into this country had been 597, 484, 217 pounds annually. The people of the United States are said to consume about one-third of the total coffee production, and in this fact, perhaps, was to be found the explanation of the proverbial nervousness of our people and the explanation of the large amount of work they are capable of doing. Dr. Love had expressed the opinion that the excessive use of coffee leads to worse results than the abuse of alcohol. Undoubtedly the morning cup of coffee had a most beneficial effect on a large proportion of our population. The popular idea that coffee can replace food or increase the capacity for work without corresponding tissue-waste was entirely erroneous. The old adage, "What is one man's meat is another man's poison," was often exemplified in regard to the action of coffee. Most physicians had given the subject little if any attention. The habitual daily indulgence in coffee, even in moderate quantities, by those susceptible to its action, invariably led to functional nervous disturbances. No doubt the addition of milk and sugar, by favoring fermentation, adds to the bad effect. Many physicians seem to think that coffee never acts harmfully if taken without milk or sugar, but this was not borne out by extended experience. All neurotic individuals seem to be more or less susceptible to coffee, and it usually aggravates any existing hyperemia in the cerebral system. He had seen persons in whom sneezing had been induced by the use of coffee. He could recall several cases of pneumonia in which caffein had been given as a heart stimulant, which had exhibited marked insomnia and great restlessness until the caffein had been withdrawn. In several patients he had been able to explain an obscure vertigo by the action of coffee. The wakefulness and ready flow of thought after taking coffee was now a commonplace observation. Nurses on night duty and many literary persons were given to taking coffee to secure this stimulating effect. The nervous system of children was peculiarly susceptible to the stimulating effect of coffee, and its use in them should never be permitted. It produces a certain precocity which is deplorable. He had often seen night terrors and tremulousness disappear in children after excluding coffee from the dietary. Several years ago he had attended a boy of 6 years, suffering from acute coffee poisoning. When seen he was in an active delirium, with a pulse of 200, tachycardia and visual and aural hallucinations. The boy had entered the bar-room of the hotel and had taken some coffee beans. These he had eaten during the evening to the extent of about half an ounce. He entirely recovered in about one week. Dr. Leszynsky said that there was a large class of neurasthenics whose nervous condition was ascribable to the use of coffee. He had carefully studied and treated about 200 such cases. Naturally many of the persons so affected were individuals who work under high pressure and are required to do a good deal of talking. They usually complain of mental depression, irritability, insomnia, bad dreams, occasional vertigo, general tremulousness, precordial oppression, cardiac palpitation, loss of appetite, frequent eructations of gas, and constipation. The symptom-complex most commonly noted was general nervousness, tremor, vertigo, restless sleep, cardiac palpitation, eructation of gas and constipation. The pulse would be found of low tension and varying in rapidity from 90 to 130. Tachycardia or bradycardia might also be present. Of course, this entire series of neurasthenic symptoms might result from other causes. Coffee-poisoning was most commonly confounded with chronic alcoholic toxemia, but the diagnosis could be made by a process of careful exclusion. The majority of those who suffer from the coffee habit, according to his experience, drink alcoholic liqours very rarely. In some cases the symptoms might appear in persons taking only three or four cups of coffee daily, but in these instances it would usually be found that very little nourishing food was taken. In acute coffee-poisoning there would be great excitability, or even delirium; in chronic coffee-poisoning the toxemia manifests itself as a depressing form of neurasthenia. Although the effects of the abuse of coffee had been known since 1705, the importance of the subject had never been adequately realized in this country. In only a few cases in his experience had bradycardia been present as a result of the abuse of coffee.

In the treatment of these patients he did not recommend in every case immediate or total abstinence. As a general rule, they should be limited to one cup of coffee in the morning, and its strength should be gradually reduced. An infusion of cocoa nibs taken in moderate quantity frequently proves acceptable as a substitute for coffee. There are many preparations on the market advertised as substitutes for coffee, but they consist of a very miscellaneous collection of substitutes. He had long since refrained from recommending any of them because their continued use had led to indigestion. Many persons in breaking off the coffee habit had thoughtlessly changed to cocoa, and had used it immoderately. As cocoa contains theobromin, which is almost identical chemically with caffein, the result could be easily imagined. Occasionally it would be necessary in these cases of coffee-poisoning to resort to the rest cure. In almost all cases a cure could be effected in from three to six months.

Therapeutics.

Hemorrhoids.

Hemorrhoids are tumors composed of the varicose dilatation of the hemorrhoidal veins, either externally or internally. Internal hemorrhoids differ from external only in that they are covered with mucous membrane instead of skin, and have a greater tendency to hemorrhage. The chief predisposing cause is the absence of valves in the hemorrhoidal veins. The direct causes are the mechanical influences which obstruct the circulation, such as sitting in the erect position; sedentary occupations; such a mode of life as leads to a constant hyperemia of the lower portion of the rectum; overeating; over-drinking of alcoholic liquors; pregnancy; excessive use of purgatives; constipation, which is usually the exciting cause of an attack, and disturbances of the liver. The important symptoms are the indications of irritation, such as itching, burning, throbbings about the anus or paroxysms of pain, and, in case of internal piles, hemorrhage is of frequent occurrence. The treatment consists to a great extent in proper regulation of diet, daily evacuation of the bowels, which should be of a soft, mushy consistence, and the proper amount of exercise. When the tumors protrude, they should be replaced slowly while the patient is stooping, first coating them with sterilized vaselin or cocoa butter.

OINTMENTS FOR EXTERNAL PILES.

℞.	Chrysarobin	gr. xv	1	
	Iodoformi	gr. v		3
	Ext. belladonnæ	gr. x		66
	Vaselini	ʒiv	16	

M. Ft. unguentum. Sig. Apply locally night and morning, first cleansing the parts well with water.

AS A LINIMENT.

Adler, in the *Cincinnati Lancet-Clinic*, states that external hemorrhoids, when inflamed or otherwise, can always be painlessly removed under cocain anesthesia, and it is at the time that they are inflamed that the operation does most good, for it not only radically removes the trouble, but it quickly alleviates the intense suffering which their presence otherwise occasions. As a liniment he recommends the following:

℞.	Ext. hamamelidis fluidi			
	Ext. hydrastis fluidi			
	Tinct. benzoini comp., āā	ʒiv	16	
	Tinct. belladonnæ	ʒi	4	
	Olei olivæ carbol—5 per cent	℥i	32	

M. Sig. Apply locally twice a day.

TO ALLAY THE IRRITATION AND ITCHING.

℞.	Extracti opii			
	Extracti belladonnæ, āā	gr. vii		4
	Lanolini	℥i	32	

M. Ft. unguentum. Sig. Apply locally.

OINTMENT.

Monroe, in the *Lancet-Clinic* gives the following ointment for the relief of his patients suffering from external hemorrhoids:

℞.	Opii pulv.	ʒi-ʒii	4-8	
	Acidi tannici	ʒi	4	
	Bismuthi subnitratis	ʒii	8	
	Adipis—borated	℥ii	64	

M. Ft. unguentum. Sig. Spread on a thick cloth or lint; apply to the anus and fasten with a bandage.

COLLODION APPLICATIONS.

Samways, in the *British Medical Journal*, advises application of collodion for the itching. It also causes the pile to contract. It should be applied on a little cotton after defecation, morning and evening.

PREVENTION OF HEMORRHOIDS.

Matthews, as reported in *The Medical Standard*, states that the best agent for the preventive and palliative treatment of internal hemorrhoids is cold water. Do not allow the patients to inject hot water into the rectum; it causes a distention of the veins and further protrusion of the hemorrhoids. Cold contracts, therefore, if your hemorrhoidal patients will drink a mineral water to keep the bowels open, will apply cold water to the mass after the bowels move, and will inject moderately cold water into the rectum to aid every movement, they will get good results. If some ointment is desirable, the following is suggested by him:

℞.	Hydrarg. chloridi mitis	gr. xl	2	66
	Morphinæ sulphatis	gr. vi		36
	Cocainæ muriatis	gr. xii		72
	Vaselini	℥i	32	

M. Ft. unguentum. Sig. Apply locally night and morning. This is especially indicated when pain is present.

ITCHING HEMORRHOIDS.

For the itching or in cases of pruritus, the following is of value:

℞.	Menthol	ʒss-i	2-4	
	Vaselini	℥i	32	

M. Ft. unguentum. Sig. Apply locally when necessary to relieve the itching.

CHRYSAROBIN IN HEMORRHOIDS.

Chrysarobin has been highly recommended by such men as Pounne, Boas and others. The following formulæ, containing this preparation, may be found useful:

AS A SUPPOSITORY.

℞.	Chrysarobin	gr. i		06
	Iodoformi			
	Ext. belladonnæ, āā	gr. 1/3		02
	Cacoa butter	gr. xxx	2	

M. Ft. suppos. No. i. Sig. One such suppository two or three times a day for internal hemorrhoids.

TO CONTRACT THE NODULES.

Ewald states that the tumors may be touched with the following solution, which tends to make them more tough and resisting, and may contract the smaller nodules:

℞.	*Potassii iodidi*	gr. xxx	2	
	Iodi	gr. iii		2
	Glycerini	ʒx	40	

M. Sig. As a local application.

SUPPOSITORY.

The Nord. Medicale gives the following formula for local application to hemorrhoids:

℞.	Cocainæ hydrochlor.	gr. xii		72
	Ergotinæ			
	Ichthyoli, āā	ʒi	4	
	Hydrarg. chloridi mitis	gr. xl	2	66
	Vaselini			
	Lanolini, āā	℥ss	16	

M. *Sig.* A portion as large as a small hazelnut to be inserted into the rectum *after each evacuation.*

INTERNAL HEMORRHOIDS.

Internal hemorrhoids which may be situated as high up as the sigmoid flexure are more difficult to deal with on account of the tendency to hemorrhage, which usually is not severe, but at times may cause great alarm. When they protrude reduction must be made carefully and slowly. Pain is present and at times severe. The most intelligent treatment under such circumstances is rest in bed, the application of cracked ice or heat in the form of hot fomentations or hot poultices made up of linseed or cornmeal or onions. Rectal injections of water at a temperature of 40 or 50 F. may be used to check the inflammation and arrest the hemorrhage.

FOR THE HEMORRHAGE.

Ewald recommends for the hemorrhages pieces of ice passed into the rectum, which is usually sufficient. Injections of astringent solutions of tannic acid 1 to 2 per cent., alum 1 to 3 per cent., acetate of lead .2 to .5 per cent., nitrate of silver .5 to 1 per cent. are also valuable.

In alarming hemorrhages it is advisable to insert tampons of absorbent wool—not cotton—saturated with a 10 to 20 per cent. aqueous solution of ferropyrin or the distilled extract of hamamelis. Wool is preferable to cotton, as it remains softer and more elastic, while cotton tampons become hard upon pressure. Opium should be given to check peristalsis. The tampon should be removed in two or three days and followed by the administration of a small dose of castor-oil or some of the saline laxatives, such as Hunyadi or vichy water.

TO OVERCOME CONSTIPATION.

Constipation should be corrected in any form of hemorrhoids. The pulvis glycyrrhizæ comp., in moderate doses, is of use under such circumstances. A preparation containing equal parts of sulphur and cream of tartar prescribed as follows, is successful in overcoming the constipation:

℞.	Sulphuris precipitatæ			
	Potassii bitartratis, āā	ʒvi	24	

M. Ft. chartulæ No. vi. Sig. One powder on rising in the morning.

Mercury in the form of hydrargyri chloridum mite in small doses is indicated when the portal circulation is sluggish. Preparations containing aloes should never be administered to patients with any signs of hemorrhoids, as aloes, even when given in moderate doses, acts almost entirely on the lower bowel, producing a congestion of its mucous membrane.

CALOMEL TREATMENT.

Detrue, in *The Medical Record*, gives the following prescription containing calomel as an ointment in hemorrhoids:

℞.	Hydrarg. chloridi mitis	gr. xxx	2	
	Morphinæ hydrochloratis	gr. 1/3		02
	Bismuthi subnitratis,			
	Vaselini, āā	℥vi	24	
	Glycerini	℥ii	8	

M. Ft. unguentum. For local application to the protruding tumors.

AS AN ANTISEPTIC.

℞.	Balsami peruviani	gr. ii		12
	Acidi borici	gr. xlv	3	
	Vaselini	℥ss	16	

M. Sig. Apply locally.

[Balsam of peru contains benzoin preparations, which are antiseptic and astringent.]

FOR BLEEDING INTERNAL PILES.

Hare gives the following formula containing gallic acid as an ointment in bleeding internal piles, and if painful from ulceration an iodoform suppository should be used:

R.	Acidi gallici	gr. x		66
	Extracti opii			
	Ext. belladonnæ. āā	gr. iv		24
	Ung. simplicis	℥iv	128	

M. Sig. Apply night and morning.

He states that great care should be used in manipulating bleeding piles, and, if of the external variety, no attempt should be made to push them inside the sphincter ani, which would constrict them.

INJECTION TREATMENT.

It has not been long since treatment of hemorrhoids by injections was in favor, and it is still being used by a great many physicians. The results and complications which very frequently follow such procedures, such as extensive inflammation and sloughing, should put us on our guard and cause us to practice economy in the employment of this line of treatment. Injections should certainly never be made when the tumors are inflamed or strangulated, as they will cause increase in the pain and swelling and tend to abscess formation.

Below are formulæ for injections that are being employed, although we do not believe that the injection method of treatment is endorsed by many scientific physicians or surgeons:

R.	*Acidi carbol.*	gr. xii		72
	Glycerini			
	Aquæ destil, āā........................	℥i	4	

M. Sig. Inject two to five minims into each hemorrhoid; or

℞.	Alcoholis—pure	m. x-xx		6-1.33
	Acidi carbolici	m. ii-v		12-.30
	Aquæ, q. s. ad	℥i	4	

M. Sig. Two to three minims to be injected along each pile as the needle is withdrawn and not more than three hemorrhoids to be injected at one treatment. If the patient is a laboring man treat only one at a time; or

℞.	*Zinci chloride*	gr. x		66
	Cocainæ hydrochloratis	gr. iv		25
	Aquæ destil..........................	℥ss	16	

M. Sig. Inject a full hypodermic syringe of this solution into the hemorrhoid; or

℞.	Acidi carbol.			
	Acidi salicylici, āā	℥iss	6	
	Sodii boratis	℥i	4	
	Glycerini	℥i	32	

M. Sig. Inject two to four minims into each hemorrhoid.

Medicolegal.

Liability of County for Care of Needy Insane.—The Supreme Court of Ohio holds, in the case of the Commissioners of Cuyahoga County vs. the City of Cleveland, that, under the Ohio statutes, the burden of caring for insane persons in needy circumstances who can not be admitted to an asylum rests upon the county in which they have their legal settlement.

Failure to Furnish Agreed Medical Attendance.—The Appellate Court of Indiana holds, in the case of the American Tin Plate Company vs. Guy, that where an employer agrees to furnish competent medical and surgical services to an employee *and his family, in consideration of a certain sum deducted* therefor from his wages, the employee has a right to rely upon *the contract, and, if he is injured by the negligent failure of* the employed to perform its part of the contract, then the employer must be responsible in damages.

As to Child Resembling Alleged Father.—The Supreme Court of Minnesota holds that it was improper, as tending to *prejudice the jury, for the prosecuting attorney to call the at*tention of the jury, in the bastardy case of State vs. Brathovde, to the supposed resemblance of the child in question, a babe in arms, which was only about three months old, to the defendant, who was charged with being its father. The supreme court observes that it is a common saying that all young babies look alike, and thinks that such an invitation would but tend to give free scope to the imagination, in attempting to test the attorney's suggestion.

Must Keep Asylum Going.—The second appellate division of the Supreme Court of New York holds, in the case of McBride vs. the City of New York, that the department of charities of the city having had imposed upon it the duty of maintaining an asylum for the care of sick children was justified in appointing a nurse to meet an exigency, after it had been informed by the secretary of the civil service commission that *it had no list of eligibles, and the city must pay the salary,* although the position was under civil service. The object of the civil service law, the court says, is to increase the efficiency of the civil service, and it declares that it can not construe it as intended by the legislature to bring an end to the business of caring for children in the asylum. The duty imposed upon the department to make provision for continuing the asylum is a public one, to which the administration of the civil service law is ancillary. It was fulfilled by the appoint*ment of the nurse.*

No Defense to Crime That Life Might Have Been Saved.—The Supreme Court of Missouri, Division No. 2, holds that there was no error in the trial judge instructing the jury, in the homicide case of State vs. Lane, that if they believed and found from the evidence that the death of the man in question resulted from the effects of a blow upon the head inflicted by the defendant with a pistol they could not, in arriving at their verdict, take into consideration the fact, if fact it was, that the man's life might have been saved, after the infliction of the blow, by a proper medical or surgical treatment. The court points out that no effort had been made to show any maltreatment of the wound, or any misconduct on the part of the deceased with reference to his wound, and that the evidence of all the physicians was to the effect that the wound caused the death. Then it adds that the judge was right in telling the jury in plain language that the post-mortem discovery that trephining at the proper time would have saved the life of the deceased was no defense whatever to the charge of homicide.

Father's Liability for Attending Child With Mother.—The second appellate division of the Supreme Court of New York declared, in the case of Dixon vs. Chapman, that it can not be the law that a physician called upon to attend an infant child by the mother is chargeable with constructive notice of the actual relations existing between the father and mother of the child, in the absence of actual notice of the facts. Moreover, it holds that it is a general rule that, if a husband living separate from his wife suffers his children to reside with their mother he is liable for necessaries furnished for them on her contracts, for as a father he has the right to the custody of the children, and may, in a proper case, obtain possession of their persons by habeas corpus; and where he does not assert that right, but suffers them to remain with their mother, he thereby constitutes her his agent to procure necessaries for them. So, in this case, the court affirms a judgment against the father for the value of medical services rendered in and about the treatment of his infant daughter, where there was in fact no evidence that the physician knew until he had rendered most of the services that the father and mother were living apart and the circumstances were such that a court would have been justified in finding that the parties were not actually separated, the father returning home about once in two weeks.

May Testify as to Acts and Exclamations of Patient.—The second appellate division of the Supreme Court of New York holds, in the case of Zingrebe vs. the Union Railway Company, that a physician may tell the jury exactly what occurred in relation to a physical examination made for the purpose of testifying in a case, in so far as these occurrences are confined to the acts and exclamations of the patient, and do not embrace statements made by the patient to the physician. It would be absurd, it thinks, to say that the physician might tell the jury, for example, as in this case, that he "pressed upon the intervertebral spaces," without telling them what results followed such pressure, as that the patient would flinch, her face would be drawn up with an expression of agony, and she would make exclamations. Here the patient was blindfolded while undergoing the examination. And the court considers that the testimony of the physician as to his observations of the patient and of her conduct at the time was properly admitted in an action brought by her husband to show the jury the extent of her injuries charged to the negligence of the defendant, not as a basis of damages, but as establishing to what extent he had been, and was likely to be, deprived of the aid, comfort and society of his wife. It also holds evidence of her pain and suffering admissible for the same purpose, and concludes that $7,250 is not excessive compensation for a man 47 years of age, with his wife about one year older, destined to go through the remaining years of his life with a wife who is not likely to contribute anything of importance to his aid, comfort or society.

AMERICAN.

1. **Infection of the Breast.**—Bacon first calls attention to the difference between infection and simple hyperemia or congestion of the breast which attends the establishment of milk-secretion or prolonged intervals between nursing. Infection of the breast, on the other hand, is generally attended with fever, and the milk fever so-called is now known to be genital wound

infection. The increase of temperature accompanying the establishment of secretion is too slight to be called fever. The question as to the mode of infection, whether through lymphatics or milk-passages, is mentioned and the importance of diagnosis between breast infection and genital wound infection is also insisted upon. The distinction must be made by a study of the prominent local symptoms. The greatest difficulty is experienced when symptoms of infection coincide with pelvic tenderness and the determination may take some time. Another important point is whether an abscess has formed; the center of infection is often quite deep and determination of fluctuation difficult. If fever or local pain continue for more than two or three days diagnostic puncture should be employed. The mode of breast infection is usually either through contact by handling of the nipples, etc., or through the child. Precautions consist in washing it in clean water before nursing and after nursing, in 75 per cent. alcohol to prevent simple abrasion or accidental infection from the mouth or skin of the child and in always covering with sterilized gauze to prevent contamination with soiled garments or bed clothing. Alcohol is used as a disinfectant because it is not harmful. Other disinfectants, such as boracic acid, are of very little disinfectant value, while carbolic acid or sublimate are poisonous. The shape of the nipple will also have much to do with infection. If too short or too small or misshaped it is more liable to be wounded during nursing. When nipple wounds become infected, and before symptoms of general infection, they may be treated as in similar wounds of other parts of the body. A little cotton saturated in alcohol is generally sufficient. Nursing through a shield may be allowed. Chills and fever generally indicate deep infection, and when they appear nursing should be entirely stopped and the breast supported and put to rest by proper bandage. Treated in this way, 80 to 90 per cent. of all breast infections will terminate without abscess. The different forms of bandage are described and a valuable adjunct to the treatment is application of cold by the ice-bag. If, in spite of all treatment, some tenderness remains and suspicion of fluctuation exists, with slight increase of temperature, the hypodermic needle should be inserted. If any abscess is present, however small, it should be opened at once. If we are in doubt as to the presence of abscess a continuance of the bandage support and the ice-bag can do no harm and is the best possible treatment. Opening of the breast is a painful operation and greatly dreaded, and Bacon recommends infiltration anesthesia, after first washing out with sterilized water, and a few sterilized threads used for drainage and antiseptic dressing applied and breast bandage and drain removed in twenty-four hours. The wound is kept open by irrigation for a day or two longer, and will close of itself.

2. **Appendicitis.**—The symptoms considered bad by Hawkes are: A rectal temperature of over 102 F.; a pulse of over 100 (if the patient is not distinctly neurotic or hysterical), or a poor pulse of any frequency whatever—and especially a pulse in which there is any tension; a thoracic respiration of over 34 (if the patient is not distinctly neurotic or hysterical); a sick appearance of the patient at any time; continued vomiting at any time; more than moderate abdominal pain; more than slight rigidity; any distention whatever; marked sweating; a chill; the slightest dilated condition, not previously present, of the superficial abdominal veins on the right side of the umbilicus, or the slightest pitting of the skin in this region on pressure; marked increase in frequency of micturition (indicating usually a long appendix reaching into the bladder region—such an appendix will almost always be found markedly inflamed); the slightest jaundice; constipation not relievable by enemata; hiccough; a sudden drop of temperature or of pulse-rate in a patient who has been sick for twenty-four hours or more (this usually means perforation with beginning general septic peritonitis); an increasing leucocytosis. He would not wait until he gets two or three of these. The presence of one of these should point the way to the operation. He is inclined to think that in every case, excepting in the mild catarrhal type of appendicitis, we shall have at least one bad sign or symptom to put us on our guard. He advises operation in all acute cases excepting those mild ones in which when first seen the patient is evidently recovering. He wishes there were a way of ascertaining in each instance whether the case will subside or not. If he sees a case for the first time after every one of the so-called bad symptoms have subsided he will be willing to allow the patient to go on to recovery without operation, having a leucocyte count made at short intervals and the patient watched very closely. The old idea about there being a time when operative procedures were in themselves more dangerous and likely to spread infection has been thoroughly proved to be erroneous. It is not the time and occurrence of attack that makes the difference, it is the operator's methods. As to the length of time that it is safe to wait after the attack has subsided, his own preference is to wait not longer than ten days. The more cases of appendicitis one sees the more conservative one becomes, using the term conservative in the sense of not allowing the patient to drift along in the channels where soundings are impossible, and where at any time, suddenly and with little or no warning, the rocks may be struck and a total wreck result. The painstaking surgeon without question saves more of his patients by operation than by any other method.

4. **Dyspeptic Asthma.**—Murdoch reports five cases of asthma suffering from various gastric disturbances, not one of whom complained of stomach symptoms, but wished only to be relieved of the distressing shortness of breath from which they suffered. Chronic dyspeptic asthma is therefore not associated with any one form of stomach trouble in particular, but primary relief can only come from restoring the digestive organs to a healthy condition.

5. **Bone Tuberculosis.**—Owen says that tuberculosis, like syphilis, is specially apt to attack the bones, but unlike the latter, it prefers the delicate growing end of the diaphysis or the spongy tissue of a small bone. He confines his remarks here, however, to tuberculous disease of the bones in the hands and feet and what he calls ultra-conservative treatment of the bones and joints. The general tenor of his article is that we are sometimes apt to carry conservative treatment too far, though he would not be considered an advocate of radical treatment in all cases, and if he makes a mistake he thinks it is in the cause of conservatism. Nevertheless, he says he has performed Symes' amputation in a very large number of cases of tuberculous disease of the tarsus in hospital work and has not had any reason to regret it in one instance.

6. **Diverticulitis.**—Darnall describes a case of inflammation of a Meckel's diverticulum, six inches in length, rising from the ileum about three and one-half feet from the ileo-cecal valve. The operation was performed for appendicitis, but this was the condition found. He is inclined to think the diverticulum here was primarily affected and the morbid process analogous to that occurring in acute gangrenous appendicitis.

8. **Menopause.**—The fallacies noted by Shoemaker are the common notion that hemorrhage above the ordinary is an essential and common feature of the normal menopause, and its consequences in the neglect of important pathologic symptoms. He thinks that the physician will avoid a blunder which will afterward be expensive to himself and to his patient if he will proceed to find out at once whether or not she is flowing too much by questioning along the following line: What is the normal of that patient in normal health? How many days' flow? The approximate time when she left the normal; question whether the flow is progressively increasing or more frequent, the amount, as far as possible, being given in figures. It will often be found that the patient has bled almost daily for many months. It may show that no periods have been actually missed or that cessation definitely occurred and in a year or more flowing began again. In this last case some form of malignant disease is almost invariably present. The normal period, it should be remembered, lasts four or five days, and the interval should not be less than three weeks. Any marked deviation from the normal or physiological must extend back into early life. If examination is indicated, it should be made at once and thoroughly. Another fallacy is

that if fibroid tumors are growing or causing disturbances the patient will do well to wait for the menopause. This idea arose when the mortality after fibroid hysterectomy was over 50 per cent. The hope that the menopause will cure the case is in itself a fallacy, and he can not recall a case of uterine fibroid which gave trouble during menstrual life that was cured after the menopause, or in other words, where it paid to wait.

11. **Whooping-Cough.**—Thompson considers heroin a valuable therapeutic agent in this disorder, allaying cough and easing respiration, and it also renders easier the removal of mucous deposits on the posterior laryngeal wall, which will aggravate the attack.

12. **Re-expansion of the Uterus in Labor.**—Benjamin commences his article by saying: "I have come to the conclusion that the parturient womb during any stage of labor, and for a few hours following, can be expanded to about the same size as it was when labor began." He describes his method as follows: Supposing, for example, an extreme case in which the head was passed through the superior strait, and has become impacted low down in the pelvis in such a position that it can not escape through the inferior strait: Anesthetize the patient, bring the hips close to the edge of the bed, elevate them well above the level of the patient's shoulders, and put an assistant in charge of each leg. Having bared and sterilized your arm and hand and applied sterilized cosmolin, begin making firm pressure with the palmar surface against the presenting portion of the head in the direction of that portion of the axis of the pelvis occupied by the head; return it by exactly the route and flexions that it came, making firm, steady pressure between the pains and holding every fraction of an inch gained when the pain comes on until it is over. It will be found to give a little between each of the pains. The process is often a long and laborious one, and since the hands and arms are apt to tire out, advantage must be taken of each opportunity to rest them without losing ground, such, for instance, as propping the elbow against the knee, and foot against the wall, or in any other manner to take the strain off the muscles, and by occasionally changing hands or being relieved by an intelligent assistant. The womb will not only begin to elongate upward, but will seem to relax its efforts, so much so that the nurse standing by will sometimes exclaim, "The pains have left her," thus, gradually the head returns above the superior strait, making room for all purposes. You can now pass your hand around the child's head in all directions and absolutely confirm your diagnosis of the position, removing the cord from its neck in the womb if necessary, or, turning the body of the child, you can firmly grasp the head and turn it in the desired direction, assisted by the other hand on the outside of the abdomen. He illustrates the value of his method by reporting a case of re-expansion of uterus and return of the child's head when there was face presentation with chin posterior.

13.—See abstract in The Journal, xxxv, p. 1367.

15.—See Proceedings of New York County Medical Association.

16. **Suprapubic Cystotomy.**—Gibson's improvement on the method of suprapubic cystotomy refers specially to details of drainage and consists in applying practically what is Kader's operation to the bladder, making the valvular opening which can be catheterized, but which when left alone will close itself. The article is illustrated to efficiently explain the text. Kader's gastric operation, as well known, consists in inverting the edges of the incision and securing them by one or more rows of inversion sutures, leaving only a space sufficient for a drainage-tube, thus filling up the wall in such a way as to make a valvular opening.

17. **Epilepsy.**—Clark summarizes the present status of surgical treatment of epilepsy as follows: 1. Idiopathic epileptics with typical grand-mal seizures should never be trephined. 2. Idiopathics in whom seizures are of the Jacksonian type should be trephined only when infantile cerebral palsies can be excluded, and when the family and personal degeneracy is at a minimum; if operation is determined upon in such cases, a very thorough removal of the epileptogenic area should be made; even then but a fraction of one per cent. recover from their epilepsy. 3. Traumatic epileptics may be trephined when the injury is definitely proved and stands in direct causal relation and has existed not more than two years. The prognosis will then largely rest upon the degree of the neurotic predisposition present. The earlier trephining is resorted to after convulsions begin, the better the prognosis. If these rules are followed, many less so-called traumatic cases will be trephined, but the result will far exceed 4 per cent. of recoveries. All epileptics trephined for whatever cause must be given post-operative bromid treatment for years. As regards the medical treatment, he remarks that no one specific should be kept up too long, and points out the evils of bromid intoxication. He prefers to give the bromids in the form of emulsion with or without cod-liver oil, in which way he finds it less irritating and less toxic and more lasting in its effects. He summarizes the present-day medical treatment by bromid in the following statements: "1. By a combination of diet, regular occupation and personal hygiene, the bromids give the best results in treating idiopathic epilepsy. 2. The bromids, singly or combined, still remain our chief sedative for the epileptic state—in the young epileptic, to secure a possible entire suppression of attacks and ultimate cure of the disease: in the adult, an amelioration of frequent paroxysms and comparative physical and mental comfort. 3. The bromids, to be effective in chronic and longstanding cases, must be given in large daily doses to suppress convulsions, from gr. ccc-cd if necessary. They should be given gradually to find the sedative level, at which level it is the physician's principal duty to maintain them with physical and mental comfort to his patient. 4. Hot and cold baths, high enemas, alimentary antisepsis, and massage are absolutely essential to successful bromid medication. 5. Bromin is a worthy substitute for the bromids in many cases in which the latter are contraindicated or can not be given in high dosage. 6. Salt starvation or semi-salt starvation is a great adjuvant to the bromid treatment, and should be thoroughly tried in all cases in which bromids or bromin are apparently contraindicated before they are discarded."

19. **Patella Suture.**—Two cases are reported by Cox in which catgut sutures were used for uniting the fragments of the patella. He points out the possibility of irritation, etc., from the use of wire suture, and advocates the method here employed.

20. **Splenic Anemia.**—A case is reported in detail by Kelly, with remarks. It is of interest largely from the fact that it occurred in a young female. There was no pronounced enlargement of the lymphatics: enlargement of the spleen was not as great as has been reported by some and the hemorrhage was from the genitals. Dyspnea was extreme, at least in the latter portion of disease. The fever was high throughout the disease, though there were one or two inexplicable drops. The author makes no special statement as regards the nature of the disease, which he considers obscure. The assumption that the enlargement of the spleen is a feature is the only basis for the successful treatment thus far. The prospects of surgical treatment are perhaps the most hopeful, though as yet undeveloped.

21. **Some Diagnostic Details.**—A plea is made by Darnall for observation of physiognomy, more especially of the eye, of inco-ordination of the muscles, breathing, position, odors, and the better appreciation of temperaments. He thinks the physician should familiarize himself with these latter so that he may know just what allowances are to be made for each type.

22. **Gonorrheal Cystitis in the Female.**—Bierhoff's article reports five cases of gonorrheal cystitis occurring in a total number of 92 cases examined. He remarks on the pathologic conditions. In one the disease was that of the body of the bladder. The other four cases presented a cystoscopic picture of cystitis coli suppurativa. He believes that cystoscopy in the female is without the dangers attending it in the male, provided the examination is preceded and followed by proper measures. In every case, however, he would strongly

recommend the microscopic examination of the sediment before any treatment is begun. As regards treatment, he thinks we possess in protargol and largin two reliable products, which, if properly used, will do all that drugs can do, and we are not justified in delaying the commencement of treatment for a single day. Besides restriction of diet and the use of frequent hot Sitz baths, we may begin the use of such remedies in the proper strength in the form of urethral and vesical irrigation at once, some of the fluid being allowed to remain in the bladder each time. In all his cases he has been able to prevent the spread of disease beyond the parts originally affected. The patients should not be dismissed, however, until the urethral discharge has completely disappeared and remains absent, even after provocatory tests, and until the urethral scrapings are epithelial in character and nearly free from gonococci, the urine normal and the cystoscope reveals a vesical mucosa free from all traces of inflammation.

26. **Lachrymal Disease.**—In cases of epiphora it is not infrequent that the condition becomes a constant menace, threatening to cause ulcer of the cornea or phlegmonous inflammation, and radical operation is apparently demanded. Lancaster discusses the indications in these cases and favors the removal of the sac as producing diminution of the cavity and size of the lachrymal gland though there is often still considerable surplus of secretion. If, however, the condition of the patient is critical the operation is only a partial success in many cases and here he favors removal of the gland itself. There are some cases where removal of the gland without removal of the sac seems to promise relief, as where, for instance, there is no obstruction to the lachrymal passage and yet the epiphora is great. Favorable results from this procedure are reported by De Wecker and others. The disadvantages or dangers of the ordinary treatment are direct and indirect. Among the first he would include the possibility of failure of preliminary healing of the wound, entailing prolonged treatment, with more or less disfiguring scars, and if infection occurs and extends to the orbit there is the possibility of orbital abscess. There is a conceivable possibility of orbital hemorrhage occurring after extirpation and the possibility of causing ptosis by damaging the levator has been suggested. So far he knows of none of these that have occurred, excepting the first. Some operators have failed to get primary union. The direct unfavorable results are the chance of having too great dryness of the cornea after extirpation of the gland. There is also the chance of injuring the cornea by lack of of care. If the eye, after the operation, should become infected, it seems a lack of irrigation would be of a decided disadvantage and necessitate frequent artificial irrigation to take the place of the natural. Against this, however, there is the fact that the removal of the sac which is the focus of infection renders such keratitis or conjunctivitis less likely to occur. He knows of but one instance of serious complication following operation for the removal of the sac and gland. This was reported by Veasey and it seems clear that the keratitis which occurred was an unusual type and not to be regarded as the result of the operation per se. He reports five cases in which he has operated, in all satisfactorily to the patient.

28. **Spinal Cocainization.**—Richardson gives his impressions derived from observation of Tuffier's operations under this method of anesthesia. The patients had the appearance of being in actual danger, with anxious facial expression, deep pallor and very feeble pulse. The condition would apparently indicate the hypodermic or intravenous infusion of normal salt solution, or at least of brisk stimulation or artificial heat. He admits that these signs may be due to psychic conditions, as he has seen similar symptoms in simple faintness from mental shock. The advantages of spinal over general anesthesia can not be demonstrated except by years of experience, and he is not at all convinced that the method is without serious dangers. It is inconceivable to him that the introduction of a needle into the spinal canal should be without danger, let alone the question of sepsis. One patient was reported as having suffered from paralysis of the bladder for several months after this method of anesthesia. A feature of general anesthesia too little appreciated is the blessed oblivion of the patient from the beginning to the end of the operation, and this is lacking here.

29. **Cervical Adenitis.**—Cobb introduces his paper with the account of a case of a child, without history of previous trouble, contracting diphtheria followed by purulent discharge from the nose, with, two years later, removal of enlarged tonsils with adenoids, and one year after this operation with a still remaining purulent discharge from the nose and cervical adenitis following an acute coryza. This case he selected because it is typical of a class met with by the general practitioner, and he points out the possible connection between purulent rhinitis in these cases and cervical adenitis, illustrating it by the case given.

31. **Tubercle Bacillus.**—Graber gives the following as a convenient, cheap and reliable stain which can be used to a decided advantage and with a great deal of satisfaction by the hampered country doctor: Fuchsin (dry), 0.50 gm.; carbolic acid, 2.50 gm.; alcohol, 5.00 c.c.; distilled water, 10.00 c.c. Mix. Mount the specimen, dry, and fix; then with an ordinary medicine-dropper completely cover cover-glass held by small pair of forceps over flame of an alcohol lamp, replacing from time to time what is lost by evaporation so as not to let the specimen get dry at the edge. Steam in this way for one minute. Wash at once in water. This can be nicely done by holding cover-glass under the tap or by moving gently back and forth in a vessel of water. Dry and apply the following: Methylene blue (dry), 2.00 gm.; sulphuric acid (U. S. P.), 24.50 c.c.; distilled water, 73.50 c.c. Mix. This is to be applied in same manner, except that no heat is used and the time should be from 30 to 60 seconds. The writer has found 50 to 59 seconds to be about right, as a rule. If stained too much or not enough, modify accordingly the time of second staining. Wash in water as before, dry, and mount. This process takes but a few minutes and is very satisfactory. The tubercle bacilli are stained a bright red, all other substances blue.

37.—See abstract in THE JOURNAL, xxxv, p. 1047.

38. **Traumatic Keloid of the Median Nerve.**—Kiliani's case is that of a woman 21 years of age who had had the median nerve cut by window glass, resected and sutured together. On admission there was found over the median nerve a spindle-shaped bulbar thickening about the size of an olive. This was excised, together with a smaller one, and the nerve united by catgut suture. Sensation returned the fourth day, motion gradually afterward, and in less than three months the patient was discharged with a useful hand. The patient was readmitted some four or five months later with a small tumor at the original site, which has since decreased. The nerve tumor is called keloid because the incision twice developed keloid in the skin, indicating that the patient's tissues had a tendency to fibrous hyperplasias. Aside from the clinical and pathological interest which the case presents, he reports the case because it shows the absorption of silk sutures in the wound. Although the silk had not disappeared, microscopical observations of the tumor showed that absorption of silk fibers had set in.

40. **Laryngectomy.**—The conclusions of Davis' article are: It is feasible to remove the larynx under eucain anesthesia. If the two operations are done simultaneously and a favorable course is pursued, the result will be brilliant, the patient being "out of bed on the fourth day." It is his belief that Delavan is right, and that preliminary tracheotomy ought to be done. We should not sacrifice safety for brilliancy. The the leaving of an esophageal tube projecting from the wound is probably unnecessary, the patient swallowing on the third day. The wound need not be tamponed, but can be closed from the upper edge of the trachea to the hyoid bone. These patients can make their wishes understood by speaking in a short time after the complete removal of the larynx. In this case it was found comparatively easy to remove the larynx from below upward, going up on one side, then across at the hyoid bone, and down the other.

41. **Double Ureter.**—A case is reported by Summers, who calls attention to the fact of possible error in using "segregators" to determine the presence and condition of both kidneys. He says it is conceivable also that mistakes might occur when reliance is placed wholly upon ureteral catheters. Prior to an extraperitoneal nephrectomy of election it is wiser to palpate through a button-hole opening for the presence of any gross pathologic condition of the opposite kidney.

45. **Giant Cells.**—Buxton's paper is a discussion of the origin and development of giant cells and their relation to disease, and he says finally: "Without quoting other authorities who reached similar conclusions, we may sum up that giant cells: 1. In myelosarcomas represent absorption of bone. 2. In other tumors, represent foreign-body intrusion. 3. In all tumors are a secondary manifestation, and do not actively contribute to their growth."

46.—See editorial in The Journal of January 12, p. 112.

47.—Ibid.

49.—This article has appeared elsewhere. See The Journal, xxxv, ¶89, p. 123.

52. **Femoral Hernia.**—Bacon's article is a very elaborate and lengthy one, discussing all the operations and methods of treatment of femoral hernia, its mechanism, anatomy, etc., and the technique of Gordon's operation, which he recapitulates as follows: The first step is the curved skin incision, with the upper leg of the curve parallel to and about three-quarters of an inch above Poupart's ligament, and the lower leg vertical over the femoral canal or the hernial tumor. The second step is the careful preparation of the aponeurosis of the external oblique muscle. The third step is the isolation of the hernial sac, and the reduction of its contents. The fourth step is the cleaning out of the fossa ovalis and femoral canal, extending the operation into both the abdominal and the pelvic cavities, so as to have a firm bed for the peritoneum to rest on. The fifth step is the resection of the sac and the suture of the peritoneum. The sixth step is the incision in the aponeurosis and the freeing of the adjacent muscles. The seventh step is the suturing of the internal oblique and transversalis muscles to the periosteum of the pubic bone, along the pecten ossis pubis, that is, to Cooper's ligament, with mattress-suture, and the felling down of the up-turned free border of these muscles by simple sutures, fastening them to the pectineal fascia. The eighth step is the closing of the incision in the aponeurosis. The ninth and final step is the closure of the skin incision.

62. **Pneumonia.**—The various methods of the treatment of pneumonia are considered by Brown, who believes that the consensus of best teaching is that the most favorable results will be obtained by careful nursing, diet and hygiene, and the systematic use of hydrotherapy during the entire course of disease. Cold sponging and cold bags seem to be most practicable, with very little use of drugs of any sort, except perhaps some heart stimulant such as alcohol or strychnia. A dose of morphin may be needed to relieve pain if the ice-bag does not furnish relief. To this must be added the use of saline infusions and various inhalations, with or without oxygen, to allay bronchial irritation, while great care should be exercised in prophylactic measures by disinfecting the sputum and sickroom.

63. **Formaldehyde in Ear Disease.**—According to Reik, the best antiseptic in otitis is formaldehyde, of which he found 1 dram to the pint of boiled water the best solution, syringing the ear twice daily and using at least a pint at each sitting. It makes a 1 to 3000 solution of formaldehyde gas. It seldom causes discomfort, and if it should a weaker solution should be employed. He has gone over the figures of the dispensary of the Johns Hopkins and Baltimore Eye and Ear Hospitals to test the value of this method and, while he has been able to trace up and secure notes of only 47 cases, the results seem to support his views. There are certain disadvantages in the use of boracic acid, such as retarding the healing of perforation of the drum, which he has no reason to believe occurs in the use of formaldehyde. He says in conclusion: "I do not wish to be understood as claiming that formaldehyde will cure all cases of otorrhea, but merely desire to state my belief, based upon the experience given, that in those cases which are susceptible of cure by syringing with an antiseptic fluid, formaldehyde will accomplish the good result with more certainty and in considerably less time than any other antiseptic employed at the present time.

64. **Cholelithiasis.**—Mitchell reports cases of gall-stone surgically treated in which material of the common duct was examined bacteriologically and pure cultures of what were apparently typhoid bacilli obtained. The specially interesting point in the case is that there was no history of typhoid fever and he is satisfied as well as one can be from the past history that the patient never had the disease. He regards the case, therefore, as one of local infection with typhoid bacilli without the presence of the symptom-complex which we call typhoid.

76. **Theodor Billroth.**—Hemmeter's article is a biographical sketch with notice of the works especially in regard to music and philosophy of the distinguished surgeon, Theodor Billroth. He believes that Billroth has cleared up portions of the subject of physical and physiologic acoustics and developed the scientific aspects of music. He has also emphasized the gaps that must be filled before we can reach more tangible results concerning the purely physiological aspects of music.

77. **Aural Defects.**—Reik's paper is based on the examination of the ears of 440 school children in which he tested the hearing and internal and external abnormalities. He thinks that while he could not draw definite conclusions from this examination, if it be anywhere near correct, the normal limit for high tones is far above 32,000, and even above 49,000 in young persons, many of whom can hear over 70,000, and some over 100,000 vibrations per second. The abnormalities of the external ear were also observed, and some of them described and figured, and he thinks there is much of interest in this particular subject. The results of his paper are given in tabulated form.

78. **Testicular Fluid.**—Walker reports experiments on the injection of testicular fluid to prevent atrophy of the prostate gland after extirpation of the testes and sums up the results as follows: The prostate gland in the injected animals presented both macroscopically and microscopically the same changes that had occurred in the uninjected ones. It may be said, therefore, that the injection of the testicular fluid has apparently no effect whatever, and one is probably justified in concluding that the atrophy of the gland is in no way connected with the absence of any substance in the testicular secretion.

79. **Laryngeal Cancer.**—Mackenzie pleads for thorough work in laryngeal cancer, especially the importance of naked-eye diagnosis, as compared with only microscopic examination of excised portions. He says in case of reasonable doubt, after weighing all the facts as regards the diagnosis: Should the next step be the removal of a portion of the diseased structure for examination? And in the face of all authority to the contrary, he says emphatically, "No." Before even considering such a proposition, if it is considered at all, the suspected growth should be examined from every point of view and this is best accomplished by the second method, thyrotomy, or even still more extensive external operation. Wherever laryngeal examination leaves reasonable doubt thyrotomy is justifiable, and even after this has been done, if there should be any uncertainty remaining, the removal of a portion should be only a measure of the very last resort. The objections he makes to this procedure are: 1. It subjects the patient to auto-infection and metastasis. 2. Stimulates the local growth. 3. The method is often inconclusive and misleading and sometimes practically impossible. The general treatment is sufficiently simple. It should be that which governs us elsewhere in the treatment of cancer. Total extirpation with neighboring portions of healthy tissue or of any possible lymphatic infection should be the general rule of practice. No operation for lymphatic cancer is complete without removal of the neck lymphatics. Other measures, such as curettement or removal of all visible disease, are not up-to-date surgery.

85. **Cephalic Version.**—After reviewing the opinions of authorities, Horn reports a number of cases in which this method was employed by himself, and discusses the results. In one case podalic version was finally resorted to. The results as far as the children are concerned, considering the conditions, are fairly good, but he does not think the method will be likely to claim general preference. It is much to be desired, however, that it be more employed not only in the interest of the children, but of the mother. In full term children the podalic version gives generally preferable results, though if one had the time and inclination he could get good results with cephalic version, though it will not impress the laity as much. In the induction of labor he does not hesitate to give it, by the combined method, when external method has been given a thorough trial and failed, the preference by far over any other method, and this should be in the interest of the child.

88.—See abstract in THE JOURNAL, xxxv, p. 1050.

89.—See abstract in THE JOURNAL, xxxv, p. 1425.

92. **Gastric Disorders.**—After describing the anatomy of the stomach and its blood-supply, Mayo notices the methods of examination. He believes that too much attention is paid to laboratory and too little to clinical examination at the present time; the two should go hand in hand and neither be neglected. For instance, the salol test for loss of motor power is unreliable, but the finding of food in the fasting stomach regularly seven hours after taking is most practical and reliable; fourteen hours after indicates stagnation or retention. For getting the outlines of the stomach neither the gastrodiaphanoscope nor gastroscope are of real use, nor can the giving of bismuth or the using of metal sounds for X-ray examination be compared in efficiency with simple dilatation with bicarbonate of soda and tartaric acid, or better still, a stomach-tube and a Davidson syringe with which it is easy to distend the stomach with air. If on distension the lesser curvature and pylorus remain in the normal position while the greater curvature lies below the umbilicus, dilatation is evident. If they are detected below the costal margin the stomach has descended. The history of the patient, his present condition and the chemical and biological examination of the gastric contents, taken into account with the position and size of the stomach, give a basis for diagnosis and as a rule indicate whether an abdominal incision would be expedient. In the beginning nearly all operations on the stomach are exploratory; for the most important primary investigation seldom relieves the exact condition. The technique of the operation is described and ulcer and its operative needs are noticed at length. Some forms of gastrectasia of uncertain origin are also dwelt upon, such as what has been called spasm of the pylorus, of which he thinks he has met with four cases; the special forms of pyloric obstruction are described by him, in which a high lying and fixed pylorus became more and more compressed as the stomach filled, and the distension finally relieved itself by copious vomiting. He thinks this is often the cause of dilatation, and has operated on four such cases. The so-called "fish-hook" pylorus in which the opening is directed upward, increases the muscular efforts and acts in a similar manner by increasing the stomach's work. As regards operation, he says gastroenterostomy is the most generally advisable and has few contraindications. Pyloroplasty may be of benefit in certain cases. As a result of his own experience he believes that much depends on the condition of the pylorus. If the abatement is high relapse may occur, the weakened muscles being unable to elevate the food. Gastroplication may be advantageous in selected cases for pyloric opening, but personally he has never met with a case where this operation seemed called for.

93. **Bacteriology of the Alimentary Canal.**—The chief points in Martin's paper are that it is erroneous to endeavor to sterilize the food which enters the alimentary canal. It is true that the alimentary canal of a newborn infant is sterile, as is also milk from the breast of the healthy mother, yet in a very short time under good conditions the bowels of children apparently in robust health are inhabited by the colon bacillus and various other forms of micro-organisms. Thousands of infants, he claims, have been starved to death under the belief that the babies are being protected by sterilized food, which, while destroying possible pathologic germs also destroys at the same time thousands of beneficial bacteria. To pretend to abrogate the functions of the stomach in clearing the food of harmful bacteria by its acid secretion and attempting to presterilize the food and filtering the water seems to him absurd.

95. **Cataphoresis.**—Williams reports a case of caries within the internal ear treated by him by filling the meatus, packing the tympanum and filling the canal with dilute hydrochloric acid and placing the pole well wrapped with cotton into the auditory canal the other pole being applied to the mastoid on the opposite side. A street current of 110 volts was used, regulated by a selector apparatus obtained from a dental supply-house. No milliamperemeter was used, but the force was graduated by the sensations of the patient, and he claims that the patient was soon able to bear for a period of thirty minutes a voltage of 36 to 40 directly through the cranium in this way. The hydrochloric acid produced slight dermatitis, which he thinks was not harmful. The patient recovered. He also claims to have treated similarly another case of antrum disease. The treatment appears rather severe and risky, and perhaps had not better be adopted too freely.

107. **Vernal Catarrh.**—This disorder, which Allport says is not properly named, is a sort of chronic hypertrophic conjunctivitis, and more than a mere catarrhal inflammation of the eyes, consisting as it does of marked epithelial hypertrophy sometimes of enormous dimensions. He would, therefore, wish to supplant the name "spring" or "vernal" given by Saemisch, by this other designation which more nearly represents the pathology. The symptoms are described and the occurrence of the disease is said to be in warm moist climates particularly. He never saw a case in Minnesota and only three cases in Illinois. It appears to be more especially frequent in Turkey, Italy, Spain, etc., and it usually occurs during the warm months. The treatment is not satisfactory, but a wash has been recommended by Van Milligan consisting of two drops of dilute acetic acid to one ounce of distilled water, which adds materially to the comfort of the patient. The author also recommends boracic acid 10 grs., sulphate of zinc 2 grs. to one ounce of water dropped in the eye, or another prescription recommended by Dr. Casey Wood, consisting of sodæ biborat., 300 grs., boracic acid, 200 grs., hydrarg. chlorid cor., 1/12 gr., and distilled water, 10 ounces. Use in the eye cup several times a day. Allport also recommends salicylic acid, 6 to 10 grs. to an ounce of lanolin or mild ichthyol ointment. He concludes his paper with the suggestion of the trial of chromic acid.

111.—See abstract in THE JOURNAL of January 12, p. 127.

119. **Rectal Diseases.**—The subject of rectal disorders is taken up by Tuttle, who endeavors to show what is necessary in examining for them and how to diagnose and treat ordinary cases. As a first suggestion he calls the attention of the practitioner to symptoms that indicate rectal examination. They are vague aching pain about the pelvis and sacral region, shooting down the leg; a sense of constriction or weight about the pelvis—especially in males—irregularity of the bowels, constipation, diarrhea, flatulence, loss of appetite, all the symptoms which constitute so-called intestinal indigestion, spasm of the bladder, dysuria without adequate cause, irregular menstruation in girls, membranous or mucous diarrhea with blood, restlessness at night, picking of the nose and a ferocious appetite in very young children. The history of the patient is important in regard to family antecedents, environments, habits and tendencies. All questions as to diarrhea, constipation, condition of stool when it does occur, straining, pain in and about the rectum, and its location and character, also vague unfavorable sensations should be inquired into, as also any discharge and its character; and protrusion around the rectum or swelling and whether it is easy or difficult of replacement. Having made all inquiries the physician is prepared to clearly judge of what he is likely to find, but no diagnosis is complete until both digital and ocular examinations are made. Tuttle objects to cleaning out of the rectum before examination to ascertain the habitual condition of the patient's bowels, however disagreeable

this may be. After having learned this, however, rectal irrigation should be given the patient and he then immediately afterward should be observed to see whether there is any protrusion or not.

120. **Appendicitis.**—While favoring radical procedure at the earliest possible moment Eades is not positive that all pain, vomiting and muscular rigidity call for operation. He believes in an appendicular colic, a functional condition without any pathology and some of these cases can not be differentiated from true appendicitis. In his practice, however, he places these cases on medical treatment for twelve hours and if the symptoms have abated in that time he does not consider operation absolutely necessary. If nausea and pain disappear, tenderness not increased, temperature normal or very slightly elevated, pulse normal, not too frequent, and the expression is good, he thinks recovery is probable. If improvement is not marked during the second twelve hours the surgeon should be called in.

128.—This article has appeared elsewhere. See THE JOURNAL, xxxv, p. 904.

136. **Antitoxin.**—Shurly tabulates the results of a later series of experiments which showed a mortality of 16.1 per cent. as compared with his 31 per cent. in his former series. He says in the conclusion of his article that we can say that the treatment of laryngeal diphtheria has reached a definite and exact procedure as sure and specific in its effects as any method in the treatment of disease can become. Antitoxin within twenty-four hours of onset, prophylactic dosage to exposed children, the use of intubation, if necessary, the enforcement of more perfect sanitary and hygienic surroundings will reduce the mortality to a very low percentage, and he also confidently believes that with serum administered twelve hours before operation the mortality of the few intubation cases that become necessary will be 5 per cent. or less.

137. **Suprarenal Extract.**—Somers enumerates the conditions in which the suprarenal extract is of value in ear diseases. The formula which he has employed is suprarenal 20 gr., phenic acid 2 gr., eucain hydrochlorate B. 5 gr., distilled water 2 drams. Macerate for ten minutes and filter. This solution he finds permanent and valuable. The conditions in which he has found the drug useful are acute inflammation of the drum or acute otitis media, together with the regular therapeutic procedures, when granulation tissue has developed in the canal and middle ear and in acute catarrhal otitis with congestion, but without perforation. In chronic suppuration of the attic, with a small perforation in Shrapnell's membrane and a scant purulent secretion the drug has not been of service and should not be used, but if perforation of the lower portion of the membrane is most often seen, the addition of suprarenal solution to the treatment will be favorable, provided the ear be thoroughly cleansed. In chronic cases where sclerosis of the lining membrane is marked, with rigid ossicles the results have not been satisfactory.

138. **Trichloracetic Acid.**—Huston sums up the advantage of trichloracetic acid as follows: It is one of the most powerful stimulants to granulating surfaces; it lessens secretions from granulating surfaces; it readily cleans off sloughs. When it is applied to wounds it does not burn at once, making it much easier to use as a stimulant. There is little or no inflammatory reaction.

141.—See abstract in THE JOURNAL, xxxv., p. 1425.

142.—Ibid.

146. **Japanese Hospitals.**—Register reports his observations of Japanese hospitals, which, though apparently few in number, appear to be entirely up to the latest ideas of scientific medicine and surgery. The hospitals specially noticed are the Imperial University Hospital and General Hospital at Tokyo, the Kioto Hospital Medical School and the Kobe Hospital. Only one is mentioned as being in a poor condition and poorly managed. The Imperial Hospital at Tokyo appears to be the medical center of Japan, where all well-to-do Japanese who have to undergo surgical operation appear to resort. He remarks that the Japanese physicians seem to be particularly adapted to certain departments in medicine, more especially minute investigation and the smaller and more delicate operations in surgery. As to microscopy their patience seems never to tire, and their preparations are elaborate to the last degree. He says the average Japanese physician would rather see a cataract operation than a hysterectomy.

FOREIGN.

British Medical Journal, January 5.

An Address on Acute Dilatation of the Heart in Diphtheria, Influenza and Rheumatic Fever. D. B. LEES.—The causes of sudden death from diphtheria are sometimes considered to be affections of the vagus nerve, but Lees finds by his studies that fatty degeneration is the much more probable cause. In fatal cases of diphtheria the cardiac muscle is often found much degenerated, and if this can be determined during life fatal syncope may be prevented. The clinical indications which should be sought for are: 1, feebleness of the pulse wave; 2, feebleness and diffusion of cardiac impulse; 3, extension of the cardiac dulness to the left; 4, feebleness of the first sound at the apex, with accentuation of the pulmonary second sound, all of which four indications of the weakened left ventricle would naturally be looked for in a heart suffering from fatty degeneration and they are all present more or less in many cases of diphtheria; 5, a sign which could not have been anticipated, but which is usually present, is marked accentuation of the aortic second sound, often very decided without tenseness of the radical pulse. One can only urge that the tension of the aorta is increased by contraction of the splenic arterioles through some central vasomotor irritation caused by the toxins. If the vascular tension is much increased at the same time that the ventricle is weakened the danger of fatal syncope is great. The physical examination of the heart is noticed by the author. He insists on the importance of percussion. The finger of the left hand is the best pleximeter and should be so applied that only the terminal phalanx is pressed upon the spot, and no pressure exerted elsewhere. In diphtheria if the dulness does not extend one finger-breadth outside of the left nipple there is usually no immediate danger, but should it extend farther than this, the case should be carefully watched. If it extends two finger-breadths there is an urgent peril and the child must not be allowed to sit up under any circumstances. This increase of dulness is sometimes very rapid, the extension from one finger-breadth to two may occur within a few hours, and is often accompanied by vomiting, which is an important danger signal, and sign of acute cardiac dilatation. When shock or acute dilatation has passed off, or if it occurs gradually, the patient may feel well, yet be in urgent danger. This apparent danger with dilated and fragile heart misleads the practitioner who does not use physical signs. Cardiac dilatation may occur at an early stage of the disease or later. In influenza there is also rapid cardiac dilatation in many cases, sometimes causing fatal symptoms. The same physical signs are to be noted with the same importance as in diphtheria. The dilatation in this disease may be permanent and give rise to very serious symptoms. Thrombosis is also of frequent occurrence, probably due to enfeeblement of the heart. Minor degrees of cardiac dilatation after influenza may cause merely a feeling of incapacity for exertion. The physical signs should be carefully noted in these cases, as undue exertion, prolonged strain, etc., may be very injurious. The same rule as to the danger-point when the dilatation exists over one finger-breadth from the nipple is to be borne in mind. In rheumatic fever, even in the most sudden type, acute dilatation seems to be present. Lees has never seen a first attack where it was absent. It is, however, less dangerous than in diphtheria or influenza. The same amount of dilatation as indicated by the extent of dulness beyond the nipple indicates less danger in rheumatism, but the rapid further extension may be serious and be attended wit vomiting as in diphtheria. The slightest suspicion of rheumatism in a child should lead to repeated and frequent examination of the heart, and even in adults more often than is generally recognized, it is the fresh rheumatism that kills by breaking down the compensation. Rheumatic and diphtheric myocarditis and fatty degeneration are found and it is probable similar conditions exist also in influenza. There is no question that in diphtheria and influenza the heart injury is due to toxins produced by well-known microbes of disease, and this, Lees deduces, is an argument in favor of the microbic theory of acute rheumatism. The conclusion of his article is an appeal for greater care and accuracy in the examination of the heart by palpation and percussion. Besides the dilatation of the left ventricle above noted as an important danger, dilatation of the right auricle, quite easily detected by percussion of the fourth right interspace and weakness of the right ventricle, detected by palpation of the epigastric region, are usually accompanied by considerable dyspnea and often by some lividity. A marked degree of dilatation of the right auricle two to three finger-breadths to the right of the sternal margin in the fourth space may indicate grave danger of death from asphyxia and be an urgent call for venesection or leeches. He says: "After a considerable experience as an examiner in medicine, I am forced to the conclusion that these facts are still very inadequately recognized, for I rarely meet with a candidate who understands the object of percussion of the heart or the proper method of procedure. He usually thinks only of the useless superficial cardiac dulness and contents himself with trying to determine a horizontal upper limit (which does not exist), and then palpating the cardiac impulse, as if that were equivalent to the left border of the dulness. The right limit of the heart he usually neglects altogether. And even some physicians of great eminence are apparently not conversant with the fact that the dulness of the right auricle normally extends one finger-breadth into the fourth right space, and that its border can be quite easily detected by careful light percussion."

Clinical and Pathological Notes on a Case of Human Actinomycosis. H. E. LITTLEDALE.—After first reporting a case with microscopic findings, Littledale remarks that there is little doubt that the micro-organism is due to different species of the streptothrix genus. The existence of different species causing actinomycosis seems to be the only way of explaining the anaerobic or aerobic conditions necessary for the growth of the micro-organism in different cases, besides the number of other variations in culture-media. The case reported was not due to aerobic organisms, but was one of what is usually known as actinomycosis, and was clinically diagnosed as such when no micro-organism was even looked for. The arrangement of micro-organisms in the tissues, their characteristics, etc.; leave little doubt that it was a streptothrix infection. Littledale says: "The extracorporeal relations of these streptothricæ and their mode of infecting the animal are still unexplained, but there have been a number of researches, especially those of Jensen and Johne, cited by Crookshank, which point to their having origin among the cereals. Several experiments by different investigators tend to show a possible connection between the tubercle and timothy-grass bacillus and actinomyces. For instance, Lubarsch and Schulze produced actinomycotic-like growths in animals from the timothy-grass bacillus and Eppinger's streptothrix. Bates produced mycelial growths with clubs in animals by injecting tubercle bacilli into the brain. The most extraordinary results were those of Friedrich and Nösske, who, by injecting definite quantities of tubercle bacilli into the left ventricle of rabbits, produced a growth of tubercle bacilli especially in the kidneys, composed of a dense mass of bacilli surrounded by a ring of clubs. These experiments, taken together, seem to suggest a possibility of our finding the primary source of tubercle bacilli among the cereals or some other members of the vegetable kingdom."

Notes on the Dialysis of the Toxins Through Collodion Walls. M. ARMAND RUFFER AND M. CRENDIROPOULO.—The authors have investigated the question whether mild toxins pass partly or wholly through the walls of collodion sacs and retain their pathogenic properties. The microbe chosen was the bacillus pyocyaneus, because its pathogenic properties have been well studied and it secretes a coloring matter rendering its recognition easy. They found that these passed through the collodion walls in small quantities, but not altogether; and the toxins filtered through the Chamberland filter, compared with toxins obtained by dialysis, showed greater pathogenic properties than the latter. The pathogenic properties of dialysed substances varied according to the length of dialysis. The nature of the liquid surrounding the sac of collodion had great influence upon the amount of toxin which dialysed through. When a collodion sac filled with bouillon was suspended in distilled water the surrounding water became far more toxic than when the surrounding media was bouillon or peptonized water. The naked-eye characters of the water also differ according to the liquids, and the bacilli themselves change. The bacilli in the collodion sacs appear, so far as they have studied them, to follow no regular rules. They say, in summing up, that the various toxins of the bacillus pyocyaneus dialyse, but not in their entirety. The time they take in thus dialysing is comparatively long, and their pathogenic properties vary according to the length of the dialysis. It is extremely probable that the immunizing substances are almost the first to dialyse. Advantage might possibly be taken of this property in the manufacturing of vaccins.

The Lancet, January 5.

An Address on Clinical Varieties of Bright's Disease. JOHN ROSE BRADFORD.—The author summarizes his views as follows: 1. That we may recognize two forms of acute Bright's disease, one characterized not only by the well-known urinary changes, but also by the presence of dropsy, the other where dropsy is absent and where the distinction between the acute Bright's disease and mere congestion of the kidney is by no means easy. 2. That there are at least two forms of chronic Bright's disease—one where the patient secretes a scanty, highly albuminous urine and becomes markedly dropsical, the course of the malady being chronic and death occurring usually either from the mere water-logging of the tissue, or from the development of inflammatory complications, or from chronic or subacute uremia. The second form is one in which the symptoms often run a latent course for an unknown period and where the patient ultimately seeks advice on account of very vague symptoms of ill-health, such as wasting, loss of strength, circulatory disturbance, or even where he does not seek advice until the onset of acute and fatal uremia. In this form of the disease dropsy is absent, the urine is abundant and pale, and it contains a considerable quantity of albumin. would seem that not only may chronic Bright's disease be chronic from the onset, but also that the two varieties are not necessarily different stages in one and the same morbid process, but represent rather the different effects of perhaps the same morbid process.

A Series of Cases of Actinomycosis. RICKMAN J. GODLEE.—The cases of actinomycosis are here reported with special reference to diagnosis. The special points which the author brings out are stated as follows: 1. The probability that this uncommon disease may be mistaken for others of every-day occurrence. 2. The possibility that for long periods and even after death no signs of the ray fungus may be present in the discharges or discoverable in the tissues. 3. The characteristic appearance of the abscess when opened. 4. Possibility of true embolic pyemia resulting, the secondary abscesses containing the ray fungus. 5. The fact that if the liver or lungs are affected a lateral curvature of the spine is likely to occur, the concavity being toward the affected side.

Deformity of the Skull Simulating Leontiasis Ossea, With Condition of Syringomyelia; No Physical Signs of Syringomyelia Present. JAMES S. COLLIER.—Collier reports a case in which syringomyelia was found in the necropsy with absence of all the usual signs of that condition, but with a close simulation both in signs and symptoms of leontiasis ossea by a thin, deformed skull and meningeal ossification, though the examination of sensibility was not, however, sufficiently thorough to absolutely exclude the presence of sensory changes, and while gliosis of the cord is sometimes met with, it is usually in young children and not in adults. Absence of usual symptoms where there was such distension of the spinal cord this may be. After having learned this, however, rectal irrigation should be given the patient and he then *immediately* afterward should be observed to see whether there is any protrusion or not.

120. **Appendicitis.**—While favoring radical procedure at the earliest possible moment Eades is not positive that all pain, vomiting and muscular rigidity call for operation. He believes in an appendicular colic, a functional condition without any pathology and some of these cases can not be differentiated from true appendicitis. In his practice, however, he places these cases on medical treatment for twelve hours and if the symptoms have abated in that time he does not consider operation absolutely necessary. If nausea and pain disappear, tenderness not increased, temperature normal or very slightly elevated, pulse normal, not too frequent, and the expression is good, he thinks recovery is probable. If improvement is not marked during the second twelve hours the surgeon should be called in.

128.—This article has appeared elsewhere. See THE JOURNAL, xxxv, p. 904.

136. **Antitoxin.**—Shurly tabulates the results of a later series of experiments which showed a mortality of 16.1 per cent. as compared with his 31 per cent. in his former series. He says in the conclusion of his article that we can say that the treatment of laryngeal diphtheria has reached a definite and exact procedure as sure and specific in its effects as any method in the treatment of disease can become. Antitoxin within twenty-four hours of onset, prophylactic dosage to exposed children, the use of intubation, if necessary, the enforcement of more perfect sanitary and hygienic surroundings will reduce the mortality to a very low percentage, and he also confidently believes that with serum administered twelve hours before operation the mortality of the few intubation cases that become necessary will be 5 per cent. or less.

137. **Suprarenal Extract.**—Somers enumerates the conditions in which the suprarenal extract is of value in ear diseases. The formula which he has employed is suprarenal 20 gr., phenic acid 2 gr., eucain hydrochlorate B. 5 gr., distilled water 2 drams. Macerate for ten minutes and filter. This solution he finds permanent and valuable. The conditions in which he has found the drug useful are acute inflammation of the drum or acute otitis media, together with the regular therapeutic procedures, when granulation tissue has developed in the canal and middle ear and in acute catarrhal otitis with congestion, but without perforation. An Address on Clinical Varieties of Bright's Disease. John Rose Bradford.—The author summarizes his views as follows: 1. That we may recognize two forms of acute Bright's disease, one characterized not only by the well-known urinary changes, but also by the presence of dropsy, the other where dropsy is absent and where the distinction between the acute Bright's disease and mere congestion of the kidney is by no means easy. 2. That there are at least two forms of chronic Bright's disease—one where the patient secretes a scanty, highly albuminous urine and becomes markedly dropsical, the course of the malady being chronic and death occurring usually either from the mere water-logging of the tissue, or from the development of inflammatory complications, or from chronic or subacute uremia. The second form is one in which the symptoms often run a latent course for an unknown period and where the patient ultimately seeks advice on account of very vague symptoms of ill-health, such as wasting, loss of strength, circulatory disturbance, or even where he does not seek advice until the onset of acute and fatal uremia. In this form of the disease dropsy is absent, the urine is abundant and pale, and it contains a considerable quantity of albumin. would seem that not only may chronic Bright's disease be chronic from the onset, but also that the two varieties are not necessarily different stages in one and the same morbid process, but represent rather the different effects of perhaps the same morbid process.

A Series of Cases of Actinomycosis. Rickman J. Godlee.—The cases of actinomycosis are here reported with special reference to diagnosis. The special points which the author brings out are stated as follows: 1. The probability that this uncommon disease may be mistaken for others of every-day occurrence. 2. The possibility that for long periods and even after death no signs of the ray fungus may be present in the discharges or discoverable in the tissues. 3. The characteristic appearance of the abscess when opened. 4. Possibility of true embolic pyemia resulting, the secondary abscesses containing the ray fungus. 5. The fact that if the liver or lungs are affected a lateral curvature of the spine is likely to occur, the concavity being toward the affected side.

Deformity of the Skull Simulating Leontiasis Ossea, With Condition of Syringomyelia; No Physical Signs of Syringomyelia Present. James S. Collier.—Collier reports a case in which syringomyelia was found in the necropsy with absence of all the usual signs of that condition, but with a close simulation both in signs and symptoms of leontiasis ossea by a thin, deformed skull and meningeal ossification, though the examination of sensibility was not, however, sufficiently thorough to absolutely exclude the presence of sensory changes, and while gliosis of the cord is sometimes met with, it is usually in young children and not in adults. Absence of usual symptoms where there was such distension of the spinal cord as occurred in this case is very rare. Skull deformities appear to be rare in syringomyelia, and where recorded they usually approach the acromegaly type, with also some other signs of acromegaly, and enlargement of pituitary body has also been found occasionally. In the present case the skull presented features very different and the deformity had been recognizable from the age of 5 years, when there was a severe injury. The calcified plates in the dura mater might also have resulted from hemorrhage occurring at this time. The author inquires whether syringomyelia could have been caused by the same injury—a fall of 20 feet on the head. It is difficult to say, however, how an excessive hemorrhage into the spinal cord could have occurred without producing some permanent alteration of the functions. In this case the patient had led an active life as a mechanic for fifteen years. There was a localized epilepsy, but no local pathologic condition to account for it.

Annales de Dermatologie (Paris), November.

Hereditary Syphilis of the Spinal Cord. P. CAZIOT.—Two cases are described of chronic meningo-myelitis of Erb's type, occurring in heredosyphilitics. Caziot urges physicians to look for indications of hereditary syphilis in examining patients with affections of the cerebrospinal axis.

Annales de la Soc. Med.-Chir. de Liege, October.

The Resources of Surgery in Uro-Genital Tuberculosis. A. HOOGE.—The indication for surgical intervention in case of abscess, fistula or fungus is formal and accepted by all. But there are differences of opinion in regard to the initial stages, especially of epididymo-testicular tuberculosis. Roux, Quénu and others advocate operating in the old chronic cases with one or more nodules, and still more urgently, in the fibrous or fibro-caseous chronic varieties, but the majority of surgeons abstain in these conditions. The results of 19 operations for tuberculosis of the prostate and of 30 for tuberculosis of the seminal vesicles are tabulated. They seem to indicate that success is more certain the more thorough the operation. The immediate results were always good. In the 19 operations on the prostate the organ was removed in 6, and patients regained their former strength in three or four instances. One of the others died in less than two years, from renal tuberculosis, and the other in four months. In this case the prostate was found completely necrosed. In all the other cases the cure was complete or partial, with no deaths reported to date. In the 30 cases of tuberculosis of the seminal vesicles operated on, the immediate results were good in all but one case, reported by P. R. Weir, in which the irritable bladder persisted. Three deaths have occurred, including two from pulmonary tuberculosis and one four years after the operation. The patients who have been seen since are in good health. Hooge concludes the list with a recent case of his own, in which marked improvement followed the operation, although the patient was in advanced pulmonary tuberculosis. The pain and retention were completely cured and the general health improved. A perineal fistula persisted in nearly all the operations reported. The favorable results of total extirpation of the prostate should encourage further intervention in this line. The lungs were affected in one-third of the cases investigated and published to date.

Bull. de la Soc. Med. des Hop. de Paris, December 6, 13 and 20.

Intoxication from Hydatid Cyst. H. DUFOUR.—An operation was refused by the patient even after the diagnosis of a hepato-pulmonary hydatid cyst had been made and 1500 gm. of fluid had been aspirated. Dyspnea preceded and continued after the puncture; urticaria appeared three days before and again two days afterward. There was also fever, but no indication of suppuration nor leucocytosis. The post-mortem examination disclosed congestion and a few nodular bunches with giant cells in the vicinity in one lung, but no evidence of the presence of the Koch bacillus. Dufour attributes all these symptoms and lesions to intoxication from the cyst and suggests the possibility of anti-hydatid serum therapy. It might sustain the patient and enable him to benefit by repeated punctures or laparotomy without succumbing to the general intoxication or toxic peritonitis so frequently noted in these cases. Linossier, in the succeeding number, reported that the fluid from a quadruple hydatid cyst of the liver, injected into rabbits and guinea-pigs showed no toxic power even at the dose of 200 c.c. per kilogram. The urine, however, killed rabbits in a dose of 35.8 c.c. per kilogram.

December 13.

Pleuritic Effusion in Myelogenic Leukemia. A. SICARD.—Widal classifies pleurisy as tuberculous, mechanical and acute. Sicard describes a case of typical myelogenic leukemia in which a left pleuritis effusion was characterized by desquamated endothelial cells, usually clumped. The hypertrophy of the mediastinal ganglia and of the spleen confirmed the assumption that it was a purely mechanical effusion in this case.

December 20.

Lymphadenoma With Polynucleosis. VAQUEZ.—The post-mortem findings suggested an infectious polynucleosis, possibly secondary to the lymphadenic affection. The polyneucleosis should take its place between aleukemic and leukemic lymphadenoma, and is possibly a transitional process liable to terminate in true myelogenic leukemia. The patient was a woman of 30 with multiple adenomata which had been developing for thirteen months. The blood showed 3,456,000 reds to 570,000 whites when first seen, and 87 polynuclear to 13 mononuclear cells. Later there were 2,520,000 reds to 300,000 whites. Arsenic and all treatment proved ineffectual, including Metchnikoff's new leucolytic serum. A cough resembling that of pertussis was accompanied by sputa which contained almost exclusively neutrophile polynuclear leucocytes, as also the urine and pleuritic fluid.

Nord Medical (Lille), December 15.

Sign of Incipient Arteriosclerosis. H. CURY.—The sign referred to was described in THE JOURNAL of July 21, 1900, p. 196. It was first pointed out by Friedmann, and consists in the lowering of the maximum of the sound of the aorta auscultated from the rear. Cury confirmed the value of the sign and considers it pathognomonic of arteriosclerosis long before it can be detected by any other measure. He found it constant in 89 advanced cases, and in a large number of apparently normal persons between 38 and 45 he observed the sign in six. Two of the six have been examined since and pronounced arteriosclerosis has been found. He found no traces of the sign in a number of persons with other pathologic conditions. The cause is probably the modification in the shape of the arch of the aorta in the incipient stages of the affection.

Beer Yeast in Diabetes. P. CATTAERT.—The writer prepared a dried preparation of yeast which was administered to four diabetics. One was a woman of 65, an old diabetic, with poor digestion, suppuration on both legs and commencing gangrene of one toe. She voided about 2250 c.c. of urine, containing on an average 101 gm. of sugar, in the twenty-four hours. After the yeast was administered the sugar dropped to 22 gm. in a week and disappeared two weeks later, with 1400 c.c. urine a day. The gangrene was arrested and the lesions on the legs healed over completely. The yeast was suspended for six weeks, when the lesions reappeared, but vanished again in two weeks after resumption of the yeast treatment. In another case a woman of 57 voided about 2 liters of urine a day, containing 80 gm. of sugar, but no albumin. The sugar disappeared after two weeks of yeast treatment, and did not reappear during the four following months. Another case was in an advanced stage, with deep gangrene of the toes; the sugar diminished from 54 to 17 gm. a day, but the gangrene progressed and the patient died. The fourth case is described in detail. The sugar diminished from 100 gm. to 4 gm. in four months of the yeast treatment and albumin increased from 5 to 14 gm. at the same time. The increase in the albumin may have been a mere coincidence, or possibly may have been due to the larger amount of nitrogen in yeast.

Revue Hebd. de Laryngologie, Etc. (Bordeaux), December 8.

Persistent Nasal Hemorrhage. COMPAIRED.—The writer has seen several cases of persistent nasal hemorrhage, always from the same nostril, without appreciable cause, and resisting all the usual measures. In a typical case, when the patient was first seen the hemorrhage had been arrested by tampons, but the writer insisted on their removal, to the horror of the anemic patient. He then examined the nose carefully, after introducing a little cocain, and found, as he expected, that the hemorrhage was due solely to a rupture in the internal branch of the spheno-palatine, which presented a varicose aspect for a short distance. The ruptured portion and the varicose region were cauterized with the iron heated dark red and held on the spot till cooled, so as not to detach the eschar. A small tampon, moistened with 5 per cent. zinc chlorid solution, was then applied and removed later by intranasal antiseptic irrigations. If success is not complete the treatment must be repeated until the desired result is attained.

Semaine Medicale (Paris), January 2.

Preventive Medical Treatment of Biliary Lithiasis. A. Chauffard.—It is Chauffard's opinion that systematic prophylactic measures will prevent recurring attacks of lithiasis and transform the disease into a latent stage equivalent to a cure. Surgical treatment is necessary only because the patients have been seen too late by physicians or have been inadequately treated. The aim should be to diminish the reflex excitability of the gall-bladder, modify its anatomical conditions and arrest or prevent the evolution of the calculous cholecystitis on the one hand, and on the other, to increase the flow of bile, rendering it more fluid and more abundant, keeping it aseptic, and to check the development of the calculi or dissolve them. These indications are met by a combination of sodium salicylate and benzoate and a compound of balsamic and resinous substances with general hygienic measures. The salicylate is given in doses of 1 to 2 gm. a day, combined with an equal amount of the benzoate, taken in two to four cachets before eating, occasionally supplemented by 1 to 2 gm. of Carlsbad salts. This treatment should be continued for ten to twenty days every month for several months or more than a year. Only by this perseverance can the desired results be attained. Every eight or ten days he orders one or two capsules of the compound which he has found extremely useful. The benzoate enhances the effect of the salicylate, while free from some of the inconveniences of the latter. The case is described in detail of a man of 45, so exhausted by seventy-four attacks of biliary colic within three years that he demanded operation. He had lost forty pounds in weight. Chauffard instituted his medical treatment as outlined above, twenty days a month at first and then ten days. The patient has not had an attack during the two years since the treatment was commenced and was able to take a long railroad journey within twenty days. The patient in another case was 80 years old and has been restored to normal health by this treatment with no attacks during the two years since.

Centralblatt f. Chirurgie (Leipsic), December 29.

Stenosis of the Larynx and Trachea Cured by a Thiersch Flap. H. Alapy.—This is the first case on record of complete cure of an impermeable stenosis of the larynx by excision of the cicatrix and implantation of a Thiersch flap. It was taken from the inner side of the thigh and applied through a slit in the larynx and trachea, after extirpation of the constricting cicatrix, which left a circular defect exposing the cricoid cartilage and the first ring of the trachea. The flap reversed outside, was placed on a roll of gauze, which was fastened in place, temporarily closing the larynx and the trachea at the spot. In eight days the larynx was turned back and the gauze removed. The skin flap was found in place completely healed. The wound was finally closed, after inserting a tube. The tenth day after the operation the patient, a 4-year-old boy, was able to breathe for an hour without the canula, which was then replaced and removed again daily, until its use could be gradually abandoned. Nine months later the cure was complete, the fistula had healed, the voice was powerful and distinct, although rather harsh. The recovery was smooth, but breathing was hampered a little at first by an inflammatory swelling of the false vocal chords. The stenosis followed diphtheria, and in spite of intermittent intubation, tracheotomy and several months of repeated dilatations, the child could breathe naturally only for a few moments after each treatment. Herczel has recently reported a flap operation of the kind, but his patient still has times of suffocation. Lénart has also applied a flap to prevent stricture after extirpation of a papilloma. The procedure is applicable only when the cartilaginous framework is still intact or but little compromised.

Muenchener Med. Wochenschrift, December 4.

The Internal Friction-Resistance of the Living Blood in Man. C. Hirsch and C. Beck.—By the apparatus shown in the cut, the writers of this communication have succeeded in determining the rapidity of the blood-current in more than a hundred different persons. This is the first application to man of the tests that have been made on animals or with defibrinated human blood, which are necessarily imperfect as the blood is not a simple solution but a fluid tissue. In the tests reported it was found that the rapidity of the circulation in the capillaries did not vary .2 of a second in the same subject in repeated investigations, but it varied in different individuals in diverse pathologic conditions, from 26 to 82 seconds. The apparatus may be applied at the bedside. It is constructed on the principle of Ostwald's, the tube B filled with calcium chlorid, the open manometer D with colored benzol. The thermostat is kept at a temperature of 38 C. and the manometer corresponds to a pressure of 400 mm. water, equivalent to 452 benzol, specific gravity .88. *The tube is unjoined* at P. and the manometer closed with the stopcock. The tube shown in left corner, natural size, is inserted in a vein in the forearm and .5 c.c. *of blood* are drawn, the amount necessary to fill the enlarged section of the tube G. The tube V is then replaced *and the* measuring apparatus put back in the thermostat. The time required for the blood to recede from X to X_1 is noted, and then the blood is aspirated again and *again, thus* allowing two to six measurements of the same sample of blood. The results obtained coincide with those recently reported by Huerthle in tests on living animals (*Pflueger's Arch.* lxxxii, *9 and 10*), and also confirm Poiseuille's laws. The writers are *now studying* with the apparatus the relations between the internal friction and the specific gravity of the blood, the difference between arterial and venous, unaltered and defibrinated blood, the alterations of the viscosity in nephritic blood and the influence of albuminoid bodies on the viscosity of the blood.

Value of Vegetable Albumin in Food. A. Loewy.—Tests conducted by the writer at the Berlin Agricultural Institute resulted in establishing that vegetable albumin is utilized by the organism the same as animal albumin, and can substitute it perfectly in equal amounts. The amount of uric acid eliminated is much diminished, probably owing to the lesser quantity of nuclein in the vegetable albumin. This fact renders the latter especially advantageous in affections of the kidneys, gout, etc.

Bacteriuria in Typhoid Fever. F. Neufeld.—In three out of twelve cases of typhoid fever examined at the Berlin Institute for Infectious Diseases the urine suddenly became turbid and was found full of typhoid bacilli. Study of these cases and of the literature shows that this bacteriuria occurs during convalescence, and may recur for months afterward. The turbidity of the urine gives ample warning and the bacteriuria is promptly cured with urotropin with no ill effects. The importance of these statements for the prophylaxis of typhoid fever, especially in the army, is evident, as bacteriuria caused by the bacterium coli is not affected by the urotropin.

Esophagoscopy for Removal of Rubber Tooth Plate. G. Killian.—Skiagraphs failed to show the tooth plate which the patient said she had swallowed, but Killian succeeded in locating it by esophagoscopy and removing it by burning it through in two places with the galvanocautery and taking out each of the three fragments separately. The esophagoscope tube was 13 mm. in diameter and 42 cm. long, while the length of the copper tube for the cautery loops was 54 cm. The plate was made to hold a single tooth and the rubber burnt through easily, not requiring much heat.

December 27.

New Research in Experimental Tetanus. L. Zupnik.—Experimental tetanus has differed from spontaneous tetanus in man by the fact that in the former the wounded extremity is first involved and that the tetanus gradually spreads from there as from a center. In man, on the other hand, the trismus is liable to be almost the first symptom. Zupnik's researches have demonstrated that this difference is due to the location of the primary infection and to the involvement or non-involvement of muscle. Injecting tetanus spores or toxins into the dorsum of the foot, the tail or the hock of an animal, caused a descending tetanus exactly the same as in man, while the same substance injected into the thigh or the inguinal region and thus brought into contact with a powerful muscle constantly induced a typical ascending tetanus. In the former case the animal would bear twice the dose that would be fatal if injected in the thigh or inguinal region, and the incubation was very much longer, but when the symptoms appeared they were more intense. It will be an interesting question to decide whether the minimal amount of protecting serum is the same in both cases. This research shows that the location of the infecting wound has an influence on the amount of tetanus toxin elaborated; also that the intensity of the tetanus corresponds to the length of time during which the bacilli were able to develop in the wound unhindered. Thus Zupnik found he could vary the intensity of the tetanus at will with the same material and the same kind of animal. Pohl has suggested that the remarkably long period of incubation in tetanus may be due to a chemical transformation of the toxin by some tissue, which has to occur before it becomes really toxic. It is possible that the muscles are the tissue involved in this task. They evidently play a very prominent part in the pathogenesis of tetanus. The animals found most susceptible were in descending order, monkeys, marmots, squirrels, guinea-pigs, mice, rats, dogs, cats and rabbits.

Influence of the Prostatic Secretion on Spermatozoa. H. Lohnstein.—In 542 tests of the prostatic secretion on 80 patients the reaction was acid 404 times, or 76 per cent.: neutral, 30 times, or 5 per cent., and alkaline in 108, or 20 per cent. In only 5 of the 80 patients was the secretion found constantly acid. Further investigation demonstrated that the presence of pus had no appreciable influence on the acidity, nor did the reaction of the prostatic secretion modify the vitality of the spermatozoa. Retained testicular secretion seems to stimulate the secretory activity of the prostate.

Heat-Stroke. M. Herford.—During the unusual heat of last summer, Herford had occasion to observe four cases of sunstroke which differed from the ordinary type in their protracted course and in the disturbances in speech noted in two, one of which has persisted to date with pronounced ataxia. In one case that came to autopsy numerous small hemorrhages were noted in various organs, in the alimentary canal, liver and endocardium, similar to the hemorrhages observed in animals exposed to severe heat. In the cases described, the symptoms indicated hemorrhages of this nature in the medulla oblongata, causing the disturbances in speech and the ataxia, resembling the "acute ataxias" observed after some infectious diseases and certain intoxications.

Physical Methods in Treatment of Croupous Pneumonia. A. Tagesson-Moeller.—The benefits of intercostal frictions, side vibrations, abdominal massage and other physical measures in the treatment of croupous pneumonia have been recognized for years by Swedish physicians. This writer tabulates the state of pulse and temperature, breathing, etc., before and after these measures and the rapid hastening of the crisis or aborting of the disease which they induce.

Wiener Klinische Rundschau, December 23.

Therapeutic Importance of Hot-Air Douche. J. Marcuse.—All the inconveniences of the usual methods of applying superheated air for local treatment are obviated by Frey's hot-air douche, which Marcuse endorses as the most effective means of treating and curing rheumatic, gouty and neuralgic affections. The simple apparatus consists of a small electromotor, with turbine bellows, the heating substance, tubes for hot and cold air and a rheostat. A stream of hot air at 100 to 200 C. isues from a mouthpiece 2.5 cm. in diameter with such force that it is still a powerful jet at a distance of 125 cm.

Magnesium Suture Material. Chlumsky.—Magnesium is the ideal absorbable material for sutures, but it is difficult to tie. This can be obviated by using it in the form of a thin, narrow ribbon instead of a wire. Chlumsky also describes a double screw made of magnesium, which he has found very serviceable in fastening together the ends of a fractured bone.

Comparative Experimental Study of Immobilization and Massage in Fractures. B. Rossi.—Experimental research on sixty-six rabbits showed that the callus formed much more rapidly when the fracture was treated with massage than with immobilization. A provisory callus was evident by the fourth day with massage and by the eighth its consistency and stability rendered any support superfluous. With immobilization this effect was not attained until the twelfth or fourteenth day. Function was completely restored by the fourteenth day with massage, but not till the thirtieth with immobilization, and the microscope showed the callus completely ossified on the twelfth day with the former treatment, but not until the twentieth, with immobilization.

Annali Della Accademia Med. Chir. di Perugia, xi, 3.

Histologic Study of Cured Gynecologic Cases. E. De Paoli.—Eighty cases are studied and reported in detail. They demonstrate that congenital malformations of the uterus, especially bicornuate uterus, frequently cause abortions and by profound alterations in the structure of the uterine substance result in an exceptional fragility of the organ and liability to uncontrollable hemorrhage, which may require hysterectomy. Congenital atresia of the vagina may accompany atrophy of the uterus, and although the former may be cured, sterility persists, owing to the infantile condition of the genital organs. In most cases conservative operations for parametritis and salpingitis require secondary operations. Periuterine hematocele frequently causes progressive, repeated hemorrhages with no tendency to spontaneous resolution. Hysterectomy for cancer of the cervix is inevitably followed by recurrence of the disease, but in case of malignant neoplasms of the endometrium, has better chances of success. Neoplasms of the endometrium may originate in the mucosa of the Fallopian tubes, in which case they present the structure of a papilloma resembling an adenocarcinoma. Decidual sarcoma presents a great variety in structure, corresponding to differences in the clinical course. Inflammatory processes in the uterus rebellious to ordinary methods of cure require hysterectomy in certain cases. It may be regarded as a prophylactic measure against cancer, especially in cases of chronic erosion, rebellious ulceration or hemorrhagic endometritis in women near the menopause. Cysts of the round ligament sometimes have no connection with Nuck's peritoneal diverticulum, but originate from the inclusion in the ligament of epithelial elements of the Wolffian bodies or of the ovary, which are in contact with it during the embryonal life. They should therefore be considered true cystoadenomata of embryonal origin.

Semana Medica (Buenos Ayres), November 8.

Yellow Fever in the Rio Janeiro Hospitals. C. Seidl.—This communication by one of the editors of the *Brazil Médico* was read at the recent Brazil medical congress and tabulates the statistics of eight years, during which 19,990 yellow-fever patients were treated at the hospital, with 8742 deaths. The figures confirm the experience of others that the disease attacks preferably whites, the young and strong, foreigners and the male sex. Native Brazilians are seldom affected and the infection seems somewhat attenuated in them. The mortality is very low among sailors. They are sent to the hospital at the first indications of the disease, and receive proper treatment at once, while fully 10 per cent. of the townspeople are not brought in until moribund. The mortality is extremely high among the Italians, who become terrorized at the mere suspicion of yellow fever, and offer little resistance to the disease, 54.53 per cent. dying, while the mortality among North Americans is 38.33 per cent. and among native Brazilians, 30 per cent.

Revista Medica (Mexico), December 1.

Scorpion Sting. M. Herrera.—The application of a ligature is theoretically indicated to prevent the penetration of the venom from the bite into the general circulation, but Herrera has witnessed two cases in which gangrene ensued, requiring amputation of the arm or finger. Sweating follows the bite and is evidently Nature's means of eliminating the poison. This sweating should be promoted and the cutaneous circulation favored. Prompt revulsive action is advantageous, such as sinapisms, friction with ammonia or multiple dry cups, with pilocarpin or some other diaphoretic internally. The chief indication, as in tetanus, is to soothe the excitability of the spinal centers. Alcohol is directly contraindicated, but chloroform, chloral, bromid and antipyrin have each their indications, particularly chloral, which Herrera administers in the dose of .5 gm. at first, following with .1 gm. to .15 gm. every fifteen minutes in the case of a child and double this amount for an adult.

Books Received.

Acknowledgment of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

A Manual of Medicine. Edited by W. H. Allchin, M.D. Lond., F.R.C.P., F.R.S. Ed., Senior Physician and Lecturer on Clinical Medicine, Westminster Hospital. Vol. II. General Diseases—Continued. Diseases Caused by Parasites, Diseases Determined by Poisons Introduced into the Body, Primary Perversions of General Nutrition, Diseases of the Blood. Cloth. Pp. 380. Price, $2.00. New York: The MacMillan Co. 1901.

A Text-Book of Pharmacology and Therapeutics, Or the Action of Drugs in Health and Disease. By Arthur R. Cushny, M.A., M.D. Aberd., Professor of Materia Medica and Therapeutics in the University of Michigan. Second Edition, Revised and Enlarged. Illustrated with 47 Engravings. Cloth. Pp. 732. Price, $3.75. Philadelphia and New York: Lea Brothers & Co. 1901.

A Text-Book on Practical Obstetrics. By Egbert H. Grandin, M.D., Gynecologist to the Columbus Hospital. With the Collaboration of George W. Jarman, M.D., Gynecologist to the Cancer Hospital, Instructor in Gynecology in the Medical Department of the Columbia University. Third Edition, Revised and Enlarged. Illustrated with 52 *Full-page Photographic Plates* and 105 Illustrations in Text. Cloth. Pp. 511. Price, $4.00 net. Philadelphia, New York, Chicago: F. A. Davis Co. 1900.

The Use of the Roentgen Ray, by the Medical Department of the United States Army in the War with Spain. (1898.) Prepared under the Direction of Surgeon-General George M. Sternberg, United States Army, by W. C. Borden, Captain and Assistant Surgeon, U. S. Army. Cloth. Pp. 98. Washington: Government Printing Office. 1900.

On Some Cirrhosis of the Liver, Being the Lumleian Lectures for the Year 1900. Delivered before the Royal College of Physicians, London. By Walter Butler Cheadle, M.A., M.D. Cantab., Fellow of the College. With Illustrations. Cloth. Pp. 109. Price, $2.00. London: Smith, Elder & Co. 1900.

Diseases of the Heart: Their Diagnosis and Treatment. By Albert Abrams, A.M., M.D. (Heidelberg), F.R.M.S., Consulting [illegible] of the Chest, Mt. Zion Hospital, and the [illegible] Francisco. Cloth. Pp. 170. Price, $1.00 [illegible] Engelhard & Co. 1900.

[illegible] and Treatment. By John W. Wainwright. [illegible] American Medical Association. Cloth. [illegible] net. Chicago: G. P. Engelhard & Co. 1900.

A Clinical Treatise on Fractures. By William Barton Hopkins, M.D., Surgeon to the Pennsylvania Hospital. Cloth. Pp. 268. Price, $4.00. J. B. Lippincott Co. 1900.

Transactions of the American Orthopedic Association. Fourteenth Session, held at Washington, D. C., May 1, 2 and 3, 1900. Vol. XIII. Cloth. Pp. 335. Philadelphia: Published by the Association. 1900.

Sanity of Mind: A Study of Its Conditions and of the Means of Its Development and Preservation. By David F. Lincoln, M.D. Cloth. Pp. 177. Price, $1.25. New York and London: G. P. Putnam's Sons. 1900.

Annual Report of the Water Commissioners of the City of Middletown, N. Y., 1900. Paper. Pp. 48. Middletown, N. Y.: L. S. & J. D. Stivers. 1900.

Report on the Source of Water-Supply for the City of Middletown, N. Y. By William R. Hill, M. Am. Soc. C. E. Paper. Pp. 7.

Constitution, By-laws and Fee Bill of the Linn County Medical Association. Organized April 19, 1898. Paper. Pp. 8.

Proceedings of the Philadelphia County Medical Society During December, 1900. Paper. Philadelphia: Published by the Society.

Change of Address.

R. Broughton, Dwight, to Riverside, Ill.

W. W. Bennett, Meadow Creek, W. Va., to Ashland, Va.

G. P. Bearman, Bowbells, to York, N. D.,

C. E. Barber, 74 Capitol Ave., to 114 Jackson St., Atlanta, Ga.

Cora White-Carpenter, 579 W. Adams St., to 167 S. Sangamon St., Chicago.

Jno. Clear, 434 Atkin St., to 107 W. Park Ave., Knoxville, Tenn.

John Evers, Chicago, to Hinsdale, Ill.

J. W. Forshey, 416 E. Rich St., to 328 E. Towne St., Columbus, Ohio.

J. H. Flynn, Ballinger Bldg., to 2406 S. 6th St., St. Joseph, Mo.

C. H. Gurney, Sewanee, to Eagleville, Tenn.,

Geo. Galloway, 850 W. Harrison to 574 W. Congress St., Chicago.

G. M. Henbest, 343 Ogden Ave., to 732 Jackson Boul., Chicago.

R. R. Hogue, Sparta, Wis., to Fort Dodge, Iowa.

W. E. Hoxie, Belmond, to Hampton, Iowa.

S. F. Hodge, 213 Woodlawn Ave., to 684 Trumbull Ave., Detroit, Mich.

F. L. McKee, Search Light, Nev., to Box 1035, Plymouth, Pa.

Alex. Moulder, 1100 Cherry St., to 512 E. 10th St., Kansas City, Mo.

C. A. O'Quinn, 312 McIntosh St., to 543 Broad St., Augusta, Ga.

G. T. Palmer, 2604 Indiana Ave., to 2961 Groveland Ave., Chicago.

J. H. Peeler, Griffith, to Woodside, N. C.

B. J. Read, Blackwell's Island, N. Y., to Bedford Springs, Va.

J. A. Simpson, Oneida, to Citizens' Bank Bldg., Chattanooga, Tenn.

D. E. Stephan, 12 W. Church St., to 24½ W. Main St., Newark, Ohio.

H. H. Shelton, Gilboa, to Zela, W. Va.

E. E. Martin, 4935 Indiana Ave., to 80 Institute Pl., Chicago.

J. W. Shanks, 456 S. Wood St., to 229 Honore St., Chicago.

G. Wood, 143 E. 35th St., to 4410 Berkely Ave., Chicago.

Drs. Woodman & Harris, 12009 Butler St., Chicago, to 11933 Stewart Ave., West Pullman, Ill.

The Public Service.

Navy Changes.

Changes in the Medical Corps of the Navy for the week ended Jan. 12, 1901:

Surgeon F. Anderson, ordered home and to wait orders when recruiting duty is completed.

Surgeon C. H. T. Lowndes, detached from the Naval Academy, Jan. 14, and ordered to the *Lancaster*.

Surgeon O. Diehl, detached from the *Lancaster* and ordered home to wait orders.

P. A. Surgeon B. R. Ward, detached from the Naval Hospital, Mare Island, Cal., Jan. 17, and ordered to navy yard, Boston.

Asst.-Surgeon J. B. Dennis, ordered to the Naval Academy, Jan. 14.

Marine-Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the U. S. Marine-Hospital Service for the seven days ended Jan. 10, 1901:

Surgeon Eugene Wasdin, granted leave of absence for fifteen days from Jan. 14.

P. A. Surgeon C. P. Wertenbaker, to proceed to Fontainebleau, Miss., for special temporary duty.

P. A. Surgeon W. G. Stimpson, to proceed to Cripple Creek, Col., for special temporary duty.

P. A. Surgeon J. A. Nydegger, to proceed to Chicago, and report to medical officer in command for duty and assignment to quarters.

Asst.-Surgeon C. E. Decker, granted seven days' extension of sick leave from Jan. 4.

Asst.-Surgeon J. F. Anderson, having been assigned to duty in the Immigration Service at Liverpool, England, relieved from duty in U. S. Consulate at that port.

A. A. Surgeon W. S. Walkley, granted leave of absence for three days.

Army Changes.

Movements of Army Medical Officers under orders from the Adjutant-General's Office, Washington, D. C., Jan. 3 *to* 9, 1901, inclusive:

Ira A. Allen, acting asst.-surgeon, from San Francisco, Cal., to temporary duty at the army and navy general hospital, Hot Springs, Ark.

Harry D. Belt, acting asst.-surgeon, from New York City, to Manila, P. I., on the transport *Wright,* for assignment in the Division of the Philippines.

Henry C. Bierbower, acting asst.-surgeon, from St. Edward, Neb., to San Francisco, Cal., en route for assignment in the Philippines.

Weston P. Chamberlain, lieutenant and asst.-surgeon U. S. A., from San Francisco Cal., to duty at Fort Adams, R. I.

Timothy F. Goulding, acting asst.-surgeon, former orders revoked; he is ordered from Boston, Mass., to New York City, to take passage on the transport *Wright,* to Manila, P. I.

Deane C. Howard, captain and asst.-surgeon, U. S. A., from Fort Hancock, N. J., to San Francisco, Cal., for transportation to Manila, P. I., and assignment to duty in the Division of the Philippines.

Thomas W. Jackson, acting asst.-surgeon, leave of absence extended.

Charles E. MacDonald, acting asst.-surgeon, from Fort Yates, N. D., to San Francisco, Cal., en route to the Division of the Philippines.

Arthur W. McArthur, acting asst.-surgeon, from Chillicothe, Mo., to Fort Yates, N. D., for post duty.

James E. Mead, acting asst.-surgeon, from Detroit, Mich., to San Francisco, Cal., en route to the Philippines.

Irving W. Rand, captain and asst.-surgeon U. S. A., from the Philippine Islands to duty as post surgeon, Fort Hancock, N. J.

Frederick P. Reynolds, major and surgeon, Vols., sick leave of absence from the Division of the Philippines extended.

Frederick W. Richardson, acting asst.-surgeon from St. Paul, Minn., to San Francisco, Cal., en route to the Philippine Islands.

Major A. W. Shockley, lieutenant and asst.-surgeon, U. S. A., leave of absence extended.

Frank E. Thompson, acting asst.-surgeon, from Cleveland, Ohio, to New York City, en route to Manila, P. I., on the transport *Wright.*

Henry A. Webber, lieutenant and asst.-surgeon, U. S. A., relieved from duty in the Department of Cuba, to New York City, for duty as acting quartermaster and acting commissary of subsistence on the transport *Wright* and subsequent assignment in the Division of the Philippines.

Archibald M. Wilkins, acting asst.-surgeon, from Delta, Ohio, to New York City, for transportation to Manila, P. I., on the *Wright*

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon General, U. S. Marine-Hospital Service, during the week ended Jan. 11, 1901:

SMALLPOX—UNITED STATES.

Alabama: Dec. 31, Girard, reported present; Phœnix, reported present.
District of Columbia: Washington, Dec. 29-Jan. 5, 6 cases.
Florida: Dec. 29-Jan. 5, Jacksonville, 1 case: West Tampa, 2 cases.
Georgia: Columbus, Dec. 31, reported present.
Kansas: Wichita, Dec. 29-Jan. 5, 12 cases.
Kentucky: Lexington, Dec. 29-Jan. 7, 2 cases.
Louisiana: Shreveport, Jan. 2, 2 cases.
Maryland: Baltimore, Dec. 29-Jan. 5, 1 case.
Minnesota: Minneapolis, Dec. 22-29, 3 cases.
Nebraska: Omaha, Dec. 22-29, 6 cases.
New Hampshire: Manchester, Dec. 29-Jan. 5, 18 cases.
New York: New York, Dec. 29-Jan. 5, 13 cases.
North Carolina: Caswell County, Dec. 1-31, 77 cases.
Ohio: Ashtabula, Dec. 29-Jan. 5, 1 case; Cincinnati, Jan. 4, 1 case; Cleveland, Dec. 29-Jan. 5, 39 cases, 1 death; Portsmouth, Jan. 5, 3 cases.
Pennsylvania: Allegheny City, Jan. 7, 1 case: Pittsburg, Dec 29-Jan. 5, 11 cases.
South Carolina: Greenville, Dec. 29, 1 case.
Tennessee: Memphis, Dec. 29-Jan. 5, 2 cases.
Utah: Salt Lake City, Dec. 29-Jan. 5, 34 cases.
Washington: Tacoma, Dec. 29, 1 case.

SMALLPOX—FOREIGN.

Austria: Prague, Dec. 8-15, 22 cases.
British Columbia: Nanaimo, Dec. 15-21, 5 cases; Vancouver, Dec. 1-31, 2 cases.
England: London, Dec. 15-22, 1 case; West Hartlepool, Dec. 9-15, 1 case.
France: Paris, Dec. 15-22, 8 deaths.
India: Bombay, Nov. 21-Dec. 4, 1 death; Calcutta, Nov. 24-Dec. 1, 7 deaths; Madras, Nov. 23-30, 1 death.
Russia: Moscow, Dec. 29-Jan. 5, 6 cases, 1 death; Odessa, Dec. 8-15, 41 cases, 10 deaths.
Scotland: Glasgow, Dec. 15-22, 72 cases, 1 death.
Uruguay: Montevideo, Dec. 1, 1 case.

YELLOW FEVER.

Colombia: Cartagena, Dec. 17, 1 death.
Cuba: Cienfuegos, Jan 8, 1 death; Matanzas, Jan. 3, 1 death.
Mexico: Vera Cruz, Dec. 22-29, 5 deaths.

CHOLERA.

India: Bombay, Dec. 4, 10 deaths; Calcutta, Dec. 1, 33 deaths; Madras, Nov. 30, 3 deaths.
Straits Settlements: Singapore, Nov. 17-24, 64 deaths.

PLAGUE.

China: Hongkong, Nov. 25, 1 death.
India: Bombay, Dec. 4, 70 deaths; Calcutta, Dec. 1, 23 deaths.
Japan: Osaka, Dec. 4-13, 3 cases: Wakayama Ken, Dec. 4-13, 5 cases; Yuasa, Dec. 4-13, plague reported.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

61 Market Street : : Chicago, Ill.

Cable Address: "Medic, Chicago"

Subscription price: Five dollars per annum in advance

Postage in the United States and Canada, Mexico, Hawaii, Guam, *Porto Rico, and the Philippines, free; foreign postage,* $2.50. Subscriptions may commence at any time. Volumes begin with the first issue of January and of July.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

The qualifications for membership require that the applicant be a member, in good standing, of a state or local medical society entitled to send delegates to the annual meeting of the American Medical Association. A list of these societies will be sent on request. Applications must be accompanied with a certificate showing that the *applicant is a member of a recognized society, and* should be sent with the annual dues—five dollars—to the treasurer, Dr. Henry P. Newman, 100 Washington Street, Chicago. Members receive The Journal free. Subscribers to The Journal may become members of the Association without additional expense if they are members of medical societies recognized by the Association. Those desiring to have their names transferred from the subscription to the membership lists should send certificates as above, with a receipt for their subscription to The Journal, covering the current fiscal year.

FISCAL YEAR.

The fiscal year of the American Medical Association is from January 1 to December 31; and the annual dues paid by a new member cover only the fiscal year, no matter at what time of year the membership is obtained. Those who pay their dues and join the Association at the annual meeting in June, for instance, *pay only for the fiscal year which ends with the December following,* and the annual dues for the following fiscal year are payable the succeeding January, at which time the treasurer sends a statement to each member. Such members, however, are entitled to The Journal for the full year, even though the membership be not continued.

PAPERS READ AT THE ANNUAL MEETING.

"Every paper received by this Association and ordered to be published, and all plates or other means of illustration, shall be considered the exclusive property of the Association. . . The Board of Trustees shall have full discretionary power to omit from the published transactions, in part or in whole, any paper that may be referred to it by the Association or either of the Sections, unless specially instructed to the contrary by vote of the Association." (From Article V of the By-laws.)

NEWS.

Our readers are requested to send us items of news of a medical nature, also marked copies of local newspapers containing matters of interest to members of the medical profession. We shall be glad to know the name of the sender in every instance.

ORIGINAL PAPERS.

Articles are accepted for publication with the understanding that they are contributed solely to this journal.

COPYRIGHT.

Matter appearing in The Journal of the American Medical Association is covered by copyright, but as a general thing, no objection will be made to the reproduction of anything appearing in its columns if proper credit be given.

CONTRIBUTIONS TYPEWRITTEN.

It will be satisfactory to all concerned if authors will have their contributions typewritten before submitting them for publication. The expense is small to the author—the satisfaction is great to the editor and printer. We can not promise to return unused manuscript.

Half-tones, zinc etchings and other *illustrations will be furnished* by The Journal when photographs or drawings are supplied by the author.

ADVERTISEMENTS.

Advertising forms go to press eight days in advance of the date of issue. Therefore, in sending in copy, time should be allowed for setting up advertisements and for the sending and return of proofs. Advertising rates will be made known on request.

CHANGE OF ADDRESS.

In ordering a change of address it is important that both the old and new addresses be given.

REMITTANCES.

Remittances should be made by check, draft, registered letter, money or express order. Currency should not be sent, unless registered. Stamps in amounts under one dollar are acceptable. Make all checks, etc., payable to "Journal American Medical Association," except those for annual dues. These should be made payable and sent direct to the Treasurer, Dr. Henry P. Newman, 100 Washington Street, Chicago.

The Journal of the American Medical Association

MENTAL SYMPTOMS OF CEREBRAL SYPHILIS.*

JAMES H. McBRIDE, M.D.

LOS ANGELES, CAL.

Syphilis may be the cause, either immediate or remote, of every form of disease of the nervous system, from neurasthenic conditions to coarse brain disease, or insanity. The reference to cases that follow will relate chiefly to conditions of mental disorder.

Insanity due to syphilis has, in many cases, characteristics which though not easy to describe, are indicative of a specific origin. There is however a small proportion of syphilitic insanity that is represented by the usual forms of mental disorder. It is quite correct to say, therefore, that syphilitic insanity may mimic every known form of mental derangement, simulating acute mania, ordinary melancholia, terminal dementia or resembling so closely paretic dementia that experts may differ in their diagnosis.

There is nothing characteristic in the mania of syphilis while the maniacal stage lasts. and the same statement applies to forms of depression due to syphilis. The history of the entire course of the attack is, however, often suggestive of a specific origin. The mania of syphilis is, in my experience, apt to be of rather brief duration and followed by mental confusion or mental weakness with intervals of quiet and semi-lucidity, showing the usual irregularity of syphilitic brain affections. The same is true of syphilitic melancholia, as there is the same irregularity, brief depression with much confusion, outbursts of excitement, periods of stupor and early dementia.

While, therefore, these forms of syphilitic mental disorder may for a brief time be quite like ordinary forms of insanity, there are few cases that will, if their entire history be considered, fail to present the irregular features mentioned, and which may often be regarded as circumstantial evidence of a specific origin.

In the majority of the cases of brain syphilis the mental symptoms are largely negative. There is a loss of mental power; of self control; of the self-regarding virtues; of moral sense, and a general lowering of the individual mentality. The memory is much impaired, only the simplest kind of reasoning is possible; the emotions are imperfectly controlled; there is a state of dullness and indifference, occasionally broken by an outburst of causeless anger, or a fit of crying, or an hour of depression with a quick return to the prevailing state of mental apathy; these are prominent characteristics of the more common form of cerebral syphilis in which mental symptoms are conspicuous. That the early symptoms of cerebral syphilis are often irregular and obscure the following case illustrates:

A groceryman, age 32, had a primary sore at 22. Five years later developed what he calls "blind spells," which still recur. Once or twice each month, usually while working hard, he suddenly becomes blind and a little confused. He sits down for a few moments when the attack passes off, and he resumes work. In January last he became confused during the afternoon and spent the greater part of the night wandering in the streets. For a month he continued to work; he recognized people readily, but could not call their names nor add a column of three figures; would give the wrong price to customers on common articles, enter still another price on the books or forget to make the entry; would ask the same question and give the same order several times. Every evening, for two months after this, he had attacks lasting ten minutes, during which he would stare wildly and talk more or less incoherently about becoming insane. These attacks ceased and he has steadily gained. He now attends to business, but is easily tired and confused and says that he lacks his former self-confidence.

The following two cases illustrate this form of syphilitic mental disorder, the form shown in mental weakness with quickly changing and incongruous delusions, with loss of memory and interests and more or less confusion of mind.

A man who had a primary sore and secondary syphilis at 31 came under my care when he was 41 for mild mental disorder that was clearly due to syphilis. His mental breakdown was probably hastened by occasional brief periods of drinking, a habit that is frequently a contributory cause of an irruption of brain symptoms in the specifically infected. He was in a state of quiet confusion, mistaking the identity of people, recognizing old friends in the physicians and attendants, who were strangers to him. He would say to-day he was in Europe, traveling for his health; to-morrow that he had been kidnaped by bandits, the next day that he was in prison for crimes he had committed, or in his own home, and yet he was quiet and contented, showing none of the interest of a traveler, the concern of a criminal in his fate, nor the anxiety of one who had been kidnapped. There was occasionally an hour when he was much depressed; at other times he would have brief periods of mental clearness, though the prevailing state was that of confusion and mental weakness, with occasional and rather indifferent reference to his delusions. During a period of six months he gradually improved and has now been entirely well for nine years.

This is the longest interval of health I have known to occur in such a case, and from my observation recoveries for such a period of time as nine years are rare. It is worth remarking here on a peculiarity of the insane syphilitic, which is the detachment of his life from his delusions. There is frequently, if not generally, an incongruity between the conduct of an insane person and his pretensions, yet this is so marked in the syphilitic insane as to have a diagnostic significance. Though the paretic does not see the inharmony between his grand schemes and his poverty and helplessness, he at least shows some earnestness and enthusiasm. The paranoiac is intense and vehement, and chafes under the indifference of his friends or the restraints of an asylum, and even the chronic delusional insane person takes pride in his fancies and sincerely believes in them.

---

* *Presented to the Section on Nervous and Mental Diseases, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.*

The syphilitic insane person of the type we are now considering has a different attitude toward his delusions. He will speak of them day after day, rarely repeating in any two successive days the same delusions and may even have no recollection to-day of those he spoke of yesterday with great detail. The chief peculiarity, however, is that he seems to have little interest in his delusions; he speaks of them without feeling, interest, or enthusiasm; they do not excite his resentment for fancied wrongs; he speaks of supposed injuries done him as though he were a third person, and repeats his delusions with the mechanical and indifferent manner of one who is reciting something from memory.

This quiet monotonous reeling off of incongruous fancies that seem to correspond to no desire, that awaken no interest, that lead to no plans, nor take shape in action, that seem to come and go like the confused and hurried impressions of a dream, are distinguishing features of this form of syphilitic insanity. The break between the thinking process and the actualizing and realizing impulses must be serious, and of a kind that is special to this condition. There must be special lines of pathologic progress, undoing with the strict orderliness of growth the complications of cerebral structure, and which is shown in the confusion of the habitual thought processes, in the peculiar dissociations of reason.

Another case of this quiet, confusional form of syphilitic insanity was that of a woman whom I treated for two years, and who had been infected by her husband. Two years after infection she showed signs of mental failure, which at first was mild depression, but in a few months passed into a condition of weak-mindedness and indifference to her surroundings. During the eight years she has now been insane there has been little change in her mental condition. She is quiet, dull and apathetic, having no interest in what is going on; indeed much of the time apparently unconscious of her surroundings, being inactive and inert mentally and physically. At times she has several hours or a day of partial sanity; she will ask anxiously for her husband and children, and speak of her home and friends. Gradually her mind relapses into the habitual state, or this may take place after a day of melancholic depression. During her dull periods her speech is mumbling and indistinct; words are omitted or recalled with effort and proper names hardly at all. During the brighter periods she speaks naturally and correctly,

This quiet, apathetic, mildly varying condition, with long periods of confusion and dulness, occasional and sudden return of apparent sanity with depression or short attacks of hysteria and return to habitual mental state, furnishes an epitome of the mental symptoms of a very common type of syphilitic insanity.

Insanity may occur in the syphilitic very soon after the appearance of secondary symptoms. One has been reported in which a man became insane with characteristic mental symptoms within three months after infection. I knew a case to develop within six months. A business man under my care showed some moral perversion, extravagance, inability to apply mind, loss of interest in family and business, with decided loss of mental vigor and brief periods of depression, within six months after contracting syphilis. A few weeks later he became very stupid, had to be dressed, and at times fed. Under treatment he made a fair recovery and resumed business for some months, when without any apparent mental failure, he became shamelessly immoral, abandoned his family, and finally disappeared. Cases of this kind have more interest for the general practitioner than some of the more severe and commoner forms of syphilitic insanity because such cases may not be committed to an asylum, but remain at large to cause the family and friends and the physician much annoyance.

The prospects of ultimate freedom from return of the disease are poor, and we should expect this to be so, for so highly organized a tissue having been injured by structural change, a tissue in which complete repair never takes place, it is hardly probable, indeed it is rarely possible, in the declining vigor of later life or in the strain of work in active life, that one should escape a return of the disease.

It is important that we appreciate the normal resistances of the body and know their limits as nearly as we can. A decayed tooth may set up a neuralgia that may continue as a habit after the removal of the tooth, because the resistances of the nerve center once weakened fail to regain the normal vigor. The doctor who has had much to do with those who have broken down from so-called overwork, that is, the worries, the anxieties, the excitements, disappointments, dissipations, irregularities of life, knows that these people rarely regain the vigor they once had and he knows, too, how difficult it is to keep them from relapsing into the morbid state. Heart-strain, neuralgias, headaches, affections of the stomach, neurasthenia, show the truth of this statement; that is, the peril of once breaking down the resistance of any part of the body. Half our work as physicians is in treating diseases that are the result of some part having been weakened from ill use and which ever after is an invalid organ, drawing a heavy pension from the system for its disability. It is true of syphilis in a special sense that it devitalizes the system, producing a vitiated tissue life that easily takes on disease and when it has once attacked the brain and thus made a positive break in its structure, it is pretty certain to return. The repairing power of the brain tissue proper is most imperfect, only functional diseases that testify to molecular change are ever repaired, so quickly does the brain take on abnormal habits and so easily does it drop to a lower level of function. The injuries done to nervous structure from syphilis are, too, not only unrepairable; but they are from their very nature, when they contain the specific poison, infection foci that multiply by many figures the chances of further disease.

It is one of the characteristics of syphilitic disease that its pathologic changes are in many if not most cases diffuse, variable and irregular, and the symptoms of syphilitic mental disorder correspond to this law, if it may be called a law. The same individual may present manifestations of wild excitement, melancholic depression and mental apathy and even stupor within a few weeks.

A man of 34, under my care suffering from syphilitic insanity, was usually quiet and slightly confused, and at such times expressed no clearly defined delusions. About once or twice a month he would be excited for three or four days, would keep walking rapidly from morning till night, preferring to walk in a circle on the lawn and carry an umbrella even on cloudy days. Said he was the Duke of Argyle, and that Queen Victoria had declared him her special favorite. He wrote letters to the queen, calling her his dearest love, and yet would make a proposal of marriage to one of his female servants if opportunity offered. He boasted of his intellectual capacity and physical prowess and was dictatorial and offensive in language. Later he would suddenly become very dull, denying his delusions and be for days too stupid to care for himself. He became very weak-minded, and finally died of hemiplegia, due to thrombosis. This was probably a case of arterial disease with starvation of the brain and slow degradation of its essential structure.

Another form of syphilitic insanity is one in which the patient is at first irritable, suspicious, and develops delusions of personal injury or persecution. He may believe others are trying to poison him or ruin his business and kidnap his family, and yet, as has been stated, there is decided mental apathy, a lack of any spirit of resentment or any thought of attempt at self-protection. Later the patient ceases to speak of his delusions, becomes weak-minded and contented and occupies himself with trivialities and simple routine work. A case of this kind was under my care for two years, and while very much enfeebled mentally, was taken home where, during an hour of depression, he drowned himself. Other cases will reverse the order of symptoms and show the quiet, easy-going demeanor of this man for some days or weeks and then suddenly become irritable and suspicious, and give expression to many delusions. Shortly there succeeds a mental dulness almost amounting to stupor and which continues for several days, from which the patient may temporarily pass into a condition of partial lucidity lasting only a few hours or a day before the return of the habitual mental state. Such cases illustrate and emphasize the statement that the symptoms of brain syphilis are variable, irregular and unpredictable in any given case. A young man of 30 who had contracted syphilis at 20 showed some mental depression and loss of memory and was taken to the hot springs. Soon after going there he became mildly melancholic. He was greatly emaciated, a very common thing in early syphilitic insanity, and at the same time showed mental confusion that was out of proportion to his depression; this being of itself suggestive of syphilitic origin. This condition continued for several weeks. He then gradually ceased to mention his ideas of sinfulness, etc., and showed symptoms of extreme dementia, was stupid and soiled himself, was fed by an attendant and for weeks was unable to walk from physical weakness and mental apathy. Afterward he came out of the state of stupor, became very irritable and suspicious, struck his attendants, broke window lights, and was rather difficult to manage. Later he was quieter and became subject to sudden attacks of extreme terror, during which he would attempt to escape from some fancied danger. After half a minute this would pass off, and he would feel dull and listless, and have no recollection of the occurrence. It was probably cerebral epilepsy. After eighteen months he was greatly improved, his mind was fairly clear though perceptibly weakened, was taken home, and in about two years died of an acute attack of brain disease.

It is a common observation that many inebriates become syphilitic, and it is often observed that the mildest degree of brain failure may lead and does lead to the drink habit, so early does the disease weaken the moral restraints. It is well known, too, that an old and latent syphilis is made active by drink, and I have found, too, that syphilitic inebriates are particularly liable to commit suicide after a drinking bout. So many people who have nervous syphilis are also inebriates that it is not easy to allot to each its etiologic value.

Other cases of syphilitic mental disorder may present mental symptoms of a systematized delusional type and continue without apparent change for years. Such cases, however, are pretty sure finally to show confusion and weak-mindedness and irregular and gross brain failure.

The relation of syphilis to paretic dementia has been much discussed, some claiming all paretic dementia is due to syphilis and others that it is only an occasional cause. Some forms of syphilitic insanity are certainly much like paretic dementia. I think that the cases that are strikingly alike are often due immediately to conditions that are alike. We know that paresis occurs in the prime of life, exceptionally in the developmental period, and that it is usually immediately due to stress, to overwork, business cares, worry and all those causes that test the endurance of men in active life over long periods. The syphilitic insanity that so closely resembles paresis usually develops under much the same circumstances, syphilis being a cause in the sense that it weakened or broke down the defenses of the system. In most cases of syphilitic insanity, there is less tendency to delusions of grandeur, more frequent paralysis of cranial nerves and, more frequently, attacks of gross brain disease leading to local softenings and focal symptoms. Recovery from syphilitic insanity apparently sometimes occurs, paretic dementia is probably never recovered from.

In addition to these types of purely mental disorder due to syphilis, there are others in which mental failure may be associated with evidences of gross brain disease and focal signs. A young man, aged 31, under my care, had ten years previously had primary syphilis, his only brother having died of syphilitic brain disease at his age. He spent money foolishly, neglected his business and indulged in immoralities. When I first saw him he was good-natured and jolly. He boasted of his travels and business ability, neither of which was extraordinary. He was somewhat confused and weak-minded, his speech being drawling, trembling and hesitating, with a dull expression and a senile tremor of his hands. One day he would be cheerful, active, interested in the news of the day, and talking agreeably and coherently, the next day he would be dull, slow of speech, and confused mentally. Later he had temporary attacks of paralysis of an arm or leg. Later in the disease he had an attack of hemiparesis with convulsions beginning in the hand of the paretic arm and extending in Jacksonian order to the entire side. With this there was a condition of quiet delirium in which he saw processions of gaudily dressed demons marching about the ceiling of his room, grinning at him and threatening and making gestures. The paralysis gradually became complete in four days, and passing into coma he died. There was no autopsy.

F. W. Mott relates the case of two brothers, both of whom had syphilitic insanity of the type of the case I have just recited, and in one an autopsy showed cortical arterial disease. My patient had also what is common in the syphilitic, a number of irregular and temporary attacks of aphasia. Charcot long ago called attention to this as being characteristic of syphilitic brain disease.

Though physicians may differ regarding the curability of general syphilis, few, I think, who have had much experience with syphilis of the nervous system, will hold that these cases are safe from a return of the disease. The man who has had brain syphilis in any form or degree, however well he may appear to be, is permanently crippled in the most vital part of his body, and he can only hope to avoid a return of the disease by a careful way of living that few men have the courage to adopt and fewer still escape relapse by adopting. When indeed can we say that one has recovered from syphilis? The word recovered must be used here in a different sense from that which it bears when applied to other diseases. Here is a man of fine physique and great endurance who shoulders his way easily through resistances and is never sick and a stranger to tire. He has a primary sore and mild secondary symptoms. He is outwardly the same as before and may go on for years in perfect health, when after some unusual stress or irregular habits the syphilis may reappear and possibly prove quickly fatal. The virus may not remain long in the system, but it certainly modifies the tissues so that their resistance to stress, to disease and to all unfavorable conditions is much reduced.

The first case in the series here reported as having recovered nine years ago has recently developed epilepsy of an irregular type. This man denied having syphilis, but his brother, who knew of his having had it, furnished the information. Under rest, treatment and steady habits, patients improve astonishingly, but from lack of care of health, dissipation or overwork, years of health may end in a relapse. Sometimes symptoms, such as headache and insomnia may return, or cranial nerve paralysis may recur, or an entirely new group of symptoms develop, indicating new brain territory involved. A syphilitic hemiplegia may be recovered from, to recur later on the same side, or on the opposite side, or on both sides, and this be the result of a debauch, or of an illness, after an interval of years of good health.

A bad heredity will, of course, add to the dangers of brain disease in those who are once infected with syphilis, the heredity being an element in the disease to the extent that it furnished a nervous system whose resistive powers were weak. The nutritional habits of such a system, though normal to it, are yet next of kin to the pathological and it is not surprising that it should have a fatal affinity for the specific virus. Many men are made of crumbly material. but if they escape stress and the incidence of special poisons, they may slip through life unscarred, but let adversity test the quality of their endurance or poisons like tuberculosis or syphilis attack their weakly organized tissues and the results are quickly serious. In some cases where the brain is involved this may be due to the complexity and instability of this highly organized tissue, which makes it an easy victim for a poison. I have seen such a large proportion of brain syphilis among intelligent people that I have come to believe that, other things being equal, the intellectual man who has contracted syphilis is more liable to have his brain attacked by it than another man who may also have had syphilis, but whose mental capacity is of a lower order.

This is apparently contradicted by what I believe to be the fact that intellectual or intelligent people are less liable to insanity than those who are ignorant or of inferior capacity, for of the vast multitude of those who annually go to our insane asylums, only a fraction are really intelligent people, a fraction much less in proportion than the relative numbers in the general population. It is essentially true, I think, with certain qualifications, that insanity is a disease of ignorance and incapacity. It represents the failures in the life-adjustments which to the intelligent are simple and easy; the cultured and intellectual are protected against insanity because of their more correct view of life, because of their variety of mental occupation, which allows them to escape that which more than any other one thing determines insanity, namely, monotony of life and unrelieved and unvarying mental strain, however rude the work may be or simple the strain.

I do not, however, believe that this law of the mental self-protection of intelligence holds in syphilis, because we have there the brain of both the dull man and that of the wise man exposed to the same poison; they are both prisoners in the same cell, with the chances in favor of the dull man, whose brain, being of a low order, is of a more primitive and stable type of structure, and therefore presents not only an older and tougher tissue to the poison, but it also presents fewer points for the poison to attack.

Though it is possible to distinguish between syphilis of the membranes, of the cerebral arteries, and of the brain tissue proper, from personal experience I should say it can only be approximately done. In cerebral arterial syphilis the symptoms are those of deprivation, the brain is starved. The gradual destruction of the brain functions proceeds unequally, however, not uniformly. The lumen of a vessel is finally closed and there is local spasm and paralysis if in a motor region, which may be early recovered from as collateral circulation is established. A few days later these collateral vessels also suffer and there is a return of the paralysis which lasts longer and is only incompletely recovered from, and then later the whole limb or the side becomes paralytic, when the vessels are permanently closed. This irregular recurrence of symptoms indicates the imperfect and haphazard blood-supply against which the starving and failing brain contends.

Coincident with this there are usually attacks of aphasia of a transient and irregular order, and due to the same condition of arterial failure. A number of times I have followed such cases from the beginning of cerebral failure through all the kaleidoscopic changes of the disease until the patients died paralytic and demented. In one case I noticed that when the patient took a long walk or played tennis he had transient spasm in the right leg and arm followed by temporary paralysis. If he talked any length of time he developed a temporary ataxic aphasia, showing what little reserve power was left to the brain as the blood-stream was gradually shut down.

Cerebral arterial syphilis may exist without meningitis, but syphilitic meningitis rarely exists without arteritis, perhaps never.

In meningeal syphilis there are local paralyses rather irregular in distribution, sensory phenomena, especially headaches and neuralgia, and cranial nerve palsies in basal meningitis. The mental symptoms are of an active kind, delirium, or even furious violence, though there may also be attacks of stupor.

The signs of gumma, though sometimes definite, depend upon their number, size and location. In a general way, it may be stated they are those of a tumor if the gumma is local.

Those familiar with nervous syphilis know how promptly specific treatment may relieve conditions that in cases other than syphilitic would be hopeless. The relief is not, however, wholly due to the specific nature of the disease, but partly to the tissue involved. F. W. Mott's investigations show what syphilitic degeneracy is in the mesoblastic tissues, the membranes, blood-vessels and lymphatics, and that the neurons are involved indirectly. If the nerve cells were directly attacked by the virus they could not be repaired, being, as they are, perpetual elements, and we would not observe those cases of quick relief of serious symptoms, as we so often do in cerebral syphilis. The disease of the membrane and vessels is, however, reparable within certain limits and the neurons may be restored to function when the pathological conditions of these parts are removed. The symptoms of cerebral syphilis may be due to various morbid processes, in one case to arterial occlusion, in another to pathologic lymph which fills the pericellular spaces and arrests or perverts the function of the neurons, in others to rapidly developed and perhaps temporary internal hydrocephalus due to stoppage of foramen of Majendie by inflammatory adhesions, according to Mott. The temporary attacks of drowsiness and stupor in cerebral syphilis are probably sometimes due to this condition. In cerebral syphilis, and also in paretic dementia, there is probably always some autointoxication from pathological conditions of blood and cerebrospinal fluid. When the myelin sheaths undergo degeneration cholin is formed, and this being a poisonous substance, is another element in the widening circle of disease.

That some people have severe general syphilis, while the nervous system escapes, and others have mild general syphilis and malignant syphilis of the nervous system, is a well-known fact. Hitzig claims that there are several toxins in syphilitic infection, and it is possible that they may have special affinities for special structures and that the activity of one and another varies in different infections. Some strains of syphilis may be more potent than others, some people are probably more susceptible than others. A French author has reported the case of a woman who infected five youths with syphilis, three of whom died of general paresis and the other two of brain syphilis. In such a case it is more probable that there was a special malignancy in the virus than that the five men were specially susceptible to syphilitic degeneracy of the nervous system.

There is no morbid condition in which it is so important to its proper understanding that its entire natural history be studied as that of insanity, and this study should include its developmental period, during which the morbid mental habits were forming and the morbid condition organizing. In this way, and only in this way, will we learn the order of progress from the beginning. This is necessary, too, not only that we may understand the disorder as a whole, but more than anything else, it promises that by thus tracking insanity to its source we may be able to achieve something in the way of its prevention. In this connection all conditions showing analogy to insanity help to explain its nature, such as conditions of mental defect, drunkenness, somnambulism and the phenomena of brain dissolution in old age.

The quiet forms of syphilitic insanity have in their symptomatology much in common with the mental history of the senile and, indeed, it may be said of all forms of insanity that they represent in some respects a premature and irregular senility. In senility we witness the slow undoing of the brain structure, which during life has been gaining in complexity, in accuracy of balance and adjustment, in multiplicity of relation, and which in senile degeneration of the brain is undone from the top, leaving the individual with the capacity of the child and with the instincts of the primitive man. The resemblance is more striking between senile mental changes and those of paretic dementia and syphilitic insanity than in other forms of mental disorder, possibly because of the more deliberate and systematic development of these special insanities. In these forms of insanity the higher faculties are easily seen to fail first, and they fail first because the delicately organized tissue of which they are the function is the last evolved and most unstable part of the brain, and therefore easiest and first involved in the degenerative process. In all cases of slow developing insanity the higher faculties are the first to go. The judicial mind fails in the summary of knowledge and in comprehensiveness of grasp, the musician loses the ability to interpret the higher conceptions of the master, the business man fails in quickness of perception and in those accuracies of judgment that divide success from failure, and all of these repeat in a general way the order of the unmaking of the brain in senility; that is, nature unravels from the last stitch that living fabric into which the generations of men have woven their experiences.

DISCUSSION.

Dr. Daniel R. Brower, Chicago—I am glad that I heard the masterful paper of Dr. McBride. I can add my testimony to his, that in the differentiation of these cases, the peculiarity of the mentality and the bizarre character of the symptoms are invaluable aids; and, again, the condition of arterial nutrition is most important. Pre-senility of the arteries, in the absence of interstitial nephritis, tuberculosis and gout, point almost unerringly to syphilis. I am also fully in accord with the paper in prognosis.

Dr. H. A. Tomlinson, St. Peter, Minn.—In these cases degenerative change takes place early in the anterior portion of the brain. In the course of this degenerative change the anterior branches of the Sylvian artery and the anterior cerebrals are the first to show marked evidence of atheroma, and the white streaking of the pia along the line of the blood-vessels appears earlier here than elsewhere. The location of these early changes explains the manifestations of mental disturbance in brain syphilis; because from these vessels comes the blood-supply to the area anterior to the precentral fissure. We all know that there are a large number of cases of syphilitic brain disease in which there is no mental disturbance whatever, and that the only evidence of nervous disease is some form of paralysis or aberrant manifestation of motor disturbance. In fact only a very small portion of those infected with syphilis become insane or suffer from nervous disease. The victims of syphilitic brain disease who become insane, so far as my limited experience goes—for we do not see much syphilis in the hospitals for the insane in Minnesota—are almost invariably the children of the tuberculous, syphilitic, or alcoholic; in other words, they are born with a limited vital potentiality, and it shows itself in the tendency of all disease changes to take the form of connective-tissue increase. For that reason there is naturally a more rapid and complete development of atheroma. This structural defect would indicate why these people are affected with degenerative changes, while those without this hereditary tendency have only the ordinary manifestation of syphilitic disease. I also want to speak of the difference in the manifestations of mental disturbance in the so-called second and third stages. I believe that early involvement of the brain in the unstable and defective after syphilitic infection is more common than is generally thought; especially when the involvement of the nervous system apparently takes the place of the ordinary external manifestations of the disease. I have had two cases in my own experience, in which I had positive evidence of the infection; both were young women married to men who had been recently infected with syphilis, by their own admission. In one case the insanity appeared in the second and in the other the third month after infection, and in neither one of them were there any of the external manifestations excepting a little sore throat. In both the mental disturbance began just as described by Dr. McBride, and passed rapidly into maniacal excitement with grandiose ideas. In those cases in which the affection comes on later, when degenerative changes in the blood-vessels are obvious, the manifestations would necessarily be those of progressive mental reduction, with confusion and cyclical outbursts of excitement. In the two cases referred to, the excitement passed into delirium and both died. Post-mortem the conditions found were characteristic of delirium; but at the base of the brain, in the anterior ascending arm of the Sylvian fissure and the lateral and third ventricles, especially about the velum and choroid plexuses, there was some thickening and exudation. There were also white streaks along the vessels of the pia over the frontal lobes. In another case, a young woman, a prostitute, was admitted to the hospital in a moribund condition. There was at the base of the brain, extending from and involving the optic commissure, on each side, a series of disc-like tumors from 1 to 4 cm. in diameter, apparently starting from the pia and destroying the cortical substance of the knee and foot of the first and second frontal convolutions and the olfactory lobe. The pia was very dense and thick. The white matter of the anterior portion of the frontal lobes was gelatinous. This girl had a history of having been insane for about seven months, and had been delirious for two days before admission. In this case the velum and choroid plexuses were also involved.

DR. H. H. LEVY, Richmond, Va.—I would like to ask those whose experience is greater than mine, whether they have observed as a precursor, or as an early symptom, of brain syphilis, a terrific pain in the middle line of the cranium, on and about the sagittal suture. In two cases which I have seen, it was an initial symptom.

DR. G. W. MCCASKEY, Fort Wayne, Ind.—I wish to emphasize the importance of the group of cases of insanity developing very early in the course of syphilis. When syphilitic insanity is spoken of, I think we generally have in mind those connected with the tertiary stage. I recently saw a case in a young attorney of 25, who contracted syphilis, and about a month later developed an acute psychosis. Death resulted, and post-mortem examination was absolutely negative. There had been temporary aphasia, such as frequently occurs as a brain symptom of syphilis. The syphilitic toxin may be fairly suspected of having produced such nutritional changes in the central nervous system as led to the insanity. However, it should be stated that the patient was a neurasthenic, and had been subjected to severe mental strain.

DR. T. D. CROTHERS, Hartford, Conn.—In my studies of the etiology of alcohol and opium cases I am continually surprised to find how often these diseases follow the infection of syphilis. Within a few weeks and in some instances months after the infection of syphilis the alcoholic craze appears. If the brain is particularly sensitive to alcohol and suffers from delirious states opium will be used and alcohol abandoned. I think I may say that from 8 to 10 cent. of the alcohol and opium cases can be traced to syphilis. Many of these persons may have been moderate users of alcohol before the infection. Others have been temperate and abstainers. It is clear to me that the poison of syphilis in many cases concentrates on certain brain centers producing irritation and exhaustion, for which alcohol and opium are most grateful narcotics. In a study of these cases it would be well to remember that the alcoholic and opium addictions are symptomatic of the degeneration of the nerve centers. This fact suggests therapeutic measures which are often very effectual.

DR. W. G. SPILLER, Philadelphia—I should like to ask Dr. Tomlinson whether he makes a distinction between secondary and tertiary syphilis in regard to the nervous system. It is the view of many neuro-pathologists that involvement of the nervous system may occur almost any time after the primary infection—a few months or many years—and that the distinction of early and late lesions can not be made in regard to the nervous system.

DR. HUGH T. PATRICK, Chicago—I should like to say a word apropos of what Dr. Spiller has just said. The sooner we abandon the old distinction between secondary and tertiary syphilis, especially in the nervous system, the better it will be. Aside from the insanity and the delirium which come with the secondaries, and which are to be classed, I believe, as disturbances due to infection, just like the disturbances of any other infection, there should be no distinction whatever made betwen secondary and tertiary changes in the diseases of the nervous system. The element of time should not be considered. I have seen in three or four months organic changes which could not be distinguished from those occurring four or five years after infection. I should like to emphasize the fact that these so-called tertiary symptoms occur as a rule within the first few years after infection, and that a period of quiescence of ten years after the first infection practically excludes brain syphilis. Brain syphilis occurring ten years after infection, that ten years having been a period of quiescence, is exceedingly rare.

DR. J. H. MCBRIDE, closing—I suppose it is essentially true that syphilis of the brain, occurring after 10 years, is rare, although I have seen cases occurring much later. Fournier mentions a case of a patient entirely well for 17 years, who then died from cerebral syphilis. Jonathan Hutchinson, Jr., has reported a case where the patient remained well for 32 years, and then died of syphilis. I have had several cases that remained well for 10 years and then were fatally affected. As to the circulation, I suppose Dr. Brower is correct. Dr. George Oliver has shown that in cases of syphilis, even soon after infection, the normal variation of the arteries on standing and reclining does not take place. I think Dr. Mott has said that syphilis never strikes without warning, and it is important that these cases should be dealt with by one who understands these warnings. On my way East I was consulted by a man who had what he called "blind spells," probably cerebral epilepsy, and who recently had an attack of confusion lasting several weeks, evidently incipient cerebral syphilis. He had been told he was bilious.

A REPORT OF SEVEN OPERATIONS FOR BRAIN TUMORS AND CYSTS.*

HERM. H. HOPPE, M.D.
Neurologist to Cincinnati Hospital; Lecturer on Neurology, Medical College of Ohio, University of Cincinnati.
CINCINNATI, OHIO.

The early wave of enthusiasm which followed the brilliant successes of Macewen, Godley, Horsley and Keen has been gradually displaced by an amount of pessimism which is unwarranted by the cumulative results of brain surgery for tumors and cysts. The pendulum has swung too far to the side of non-interference. This has been the direct result of numerous unwarranted operations in cases of suspected brain tumor, or in cases where the tumor was not accurately located. I feel safe in saying that hundreds of such cases, at a very low estimate, have been operated upon, which will never be spread on the annals of surgery or neurology. These are the cases which have done great damage and have been the cause of the pessimism which prevails, not only among the profession at large, but what is far worse, among the laity, who are only too apt to remember the failures and forget the successes, especially if the former outnumber the latter.

It is true that the enthusiastic hopes and predictions of the early enthusiasts have not been verified, but the fact remains that the fields for brain surgery for tumors and cysts, although very much narrowed, is still a considerable one, and one in which relief can be given and much good done. Pessimism always leads to inactivity and nihilism. Many a life could be prolonged, made more comfortable, and even saved, if the general practitioner and the general public once more felt the confidence born of successful results obtained in well-selected cases. Even in the latter, the mortality will always be great on account of the unwillingness of patients to be operated upon in the early stages. But, if we consider, that with the extremely rare exceptions all cases of brain tumor are fatal, even the large mortality will not deter us from, not only advising, but urging operations. It would seem too much to hope that the history of cancer operations might be repeated in brain surgery, but the principle is the same, and the success might be equally brilliant if, as in cancers, operations are done early on well-selected cases. In this way we may hope that the confidence of the general practitioner and of the public will be restored.

---

* Presented to the Section on Nervous and Mental Diseases, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

Case 1.—Mr. L., aged 32, was admitted to the Cincinnati Hospital, June 22, 1893. His family history was negative; he denied syphilis and gonorrhea, and had never been sick before. He stated that his trouble began three years ago with cramps in the left foot and arm; which came on at intervals of a few months. About six months before his admission they became more frequent. The convulsions invariably began in the left foot, extending up the left leg, arm and face and then became general, and after lasting a few minutes, were followed by unconsciousness and somnolence. He had violent headaches and frequent attacks of vertigo, but had never vomited. His mental condition had deteriorated somewhat, and he had become apathetic.

The examination was entirely negative; the left papilla was somewhat injected and the margins were indistinct. There was no weakness of the left side of the body, or of the left extremities, and no loss of sensation.

On June 24, the patient had another typical convulsion, as described above, which was followed by a well-marked weakness of the left arm and leg, with increased tendon reflexes, but no disturbance of sensation. The trouble was now diagnosed as tumor in the right foot center. On June 28, 1893, Dr. Ransohoff trephined over right foot center, and extended opening over superior right parietal lobe. There was no bulging of the dura mater, but when it was opened the tumor was found in the region of right foot center extending over into the parietal lobe. It was the size of a hen's egg; its cavity clean, and it seemed to spring from the pia mater. The tumor was shelled out with but little difficulty; the wound healed by first intention, but there was a boggy, protruding condition of the skin and subcutaneous tissue.

On awakening from the anesthetic there was found a total paralysis of the left arm, and the patient was not able to make even slight movement of the fingers. He had recurrence of his epileptic attacks once, a few days after the operation. With this exception the recovery was uninterrupted—no fever at any time. In a few weeks he was able to get up, and in six weeks left the hospital. There remained, however, a slight paresis of the left arm and leg, with slight spastic rigidity.

Seven years after the operation the patient is still alive; there has never been any recurrence of the tumor; the hemiparesis has, however, increased; his mental condition is good, though he has occasional epileptic seizures of the Jacksonian type. In this case the operation saved the life of the patient; relieved his head symptoms and diminished very markedly the number of epileptic seizures, although it failed to completely cure him.

Case 2.—T. B., aged 18, occupation coal miner, was admitted to Cincinnati Hospital July 15, 1893. His family history was negative; there was no history of tuberculosis, phthisis, or syphilis. According to his father, the trouble began in the latter part of December, 1892, when the patient fell and is supposed to have struck the back of his head. Close questioning revealed the fact that headache, dizziness and nausea existed for some time before the fall, which was probably the result of the vertigo. Afterward these symptoms increased, with the exception of the vomiting, which the patient had only occasionally. After the fall a growth existed on the back of the head which at first was the size of a pea, but gradually increased until it became the size of an English walnut. About January 1 the vision began to be impaired; this defect increased until the patient could distinguish only between shadow and light. Close examination revealed the fact that the early trouble with the sight was a gradual loss of the vision on the left side of the nose; left hemianopsia preceded the total loss of vision.

Physical examination showed that the patient's mental condition was apathetic, but otherwise normal; well-marked choked discs which were passing into an atrophic state; total blindness; pupils equal in size; no light reaction; fading choked disc. In the left occipital region about an inch above and an inch to the left there was an elastic tumor which was about the size of an English walnut. It protruded through the calvarium, the opening being somewhat larger than a silver dime. The margins were sharp and elevated. The tumor had a semisolid elastic consistency, and could be pushed back into the cranial cavity, almost completely. This, however, increased the headache and vertigo, and caused nausea. There were no other physical signs whatever.

A semilunar flap was made directly over the tumor. This exposed at once a pulsating mass protruding through an opening in the calvarium, and pushing before it the dura mater, which formed a sort of sac. An incision was made through the dura mater, which was followed by the escape of a large quantity of fluid. It was removed, and although the tumor itself was not so large—size of a German walnut—an opening or cavity was present in the occipital lobe, almost oval in shape, about three inches long and two inches wide. The limiting membrane was very soft and jelly-like. The cavity seemed to be very clean; the shreds of pia mater were snipped away and the cavity was tamponed with bichlorid gauze. The dura was not closed. On the third day removal of the dressing was followed by a discharge of turbid fluid.

The patient had an uneventful recovery; his vision improved and he returned home two weeks after the operation.

The diagnosis was glioma of the occipital lobe. Some time after the operation the patient presented the following condition: At the site of the cranial opening there was a soft bulging mass about three inches in diameter; there was no return of tumor; he could read the headlines of newspapers, and could tell the time from a watch; he saw everything perfectly; did not read fine print; his discs were very white.

This patient has disappeared from view, but was alive and at work as a coal miner, and able to see well three or four years after the operation.

Case 3.—A. G., aged 22, a machinist, was admitted to Cincinnati Hospital May 15, 1894, because of cystic dilatation of the diploic vein, and Jacksonian epilepsy. His pathologic history was negative. The previous history showed that he began to have convulsions at the age of 7, but after a while these disappeared, but reappeared when he was 14, and since then he has been having them every month. The convulsions were always preceded by a sensation of numbness, and formication of the left leg. Convulsions began in the left leg, then left arm and became general. He did not suffer from headache, vomiting or vertigo.

The physical examination was negative. The epileptic seizures were followed by maniacal attacks, during which the patient became very violent, showing a tendency to attack other patients in the ward. He was blindly destructive and had to be retained with shackles; the attack is typically mania and never lasts longer than twenty-four hours. He did not remember what occurred during the maniacal condition, and immediately after an attack he was dull and apathetic. The pupils were equal in size; responded to light and accommodation, and the external muscles of the eyes were normal. There was no disturbance of sensation of scalp or face; no evidence of injury or depression of skull; region supplied by seventh nerve was normal; the pharyngeal and palate reflexes normal. There was no loss of muscular power or sensation in either arm or leg; slight exaggeration of reflexes in left leg; no ankle clonus; no muscular weakness whatever of the left leg. The diagnosis was Jacksonian epilepsy.

June 21 to July 11 he worked around the ward and felt perfectly well. On May 15 he complained of pain in the left leg and arm Bromid, 30 grains, was ordered every four hours. About 10 o'clock he complained severely of pain in the left leg, which was bandaged; following this was a delirium in which the patient cried and laughed; this lasted an hour and then he became quiet. During that time he was given chloral, 20 grains, and bromid 30 grains; he went to sleep at once and slept until morning. On June 26 he had two slight hysterical attacks, but was better next day, and was discharged at his own request. He had bromids and chloral since May 12, and had no epileptic attack since his admission.

July 30, 1894, the patient was re-admitted to the hospital. He admits having had gonorrhea but denies syphilis. Because of advisability of performing an operation his relatives were summoned and they gave a somewhat different history from the patient. The latter states that he has had attacks since the age of 7; his sister says that the attacks began in the twelfth year, three months after being struck on the back of the head with a brick. She states that he was brought into the city hospital unconscious, and was discharged in about a week. No record can be found. The examination of his head over the occiput reveals no scalp wound or depression of skull. The sister agrees with the patient as to the characteristic feature of the attack, that is, that it always begins in the left leg and extends to the left arm and face and then becomes general. She also says that he has attacks during which twenty-five to thirty convulsions occur in as many hours the patient often being unconscious during the entire period. During the last few days of August the patient complained of pain in the head. One night he had three convulsions, each lasting some minutes, and all characterized by muscular contractions beginning upon the left side. In the first one the *left leg was flexed first. He slept soundly between the seizures.* A fourth attack followed, the next morning. This was witnessed by the day nurses, and they say it was of the same general character as those described by the night nurse. Later the patient suddenly got out of bed and was caught in the act of jumping out of the window. He complained of great cephalalgia, was restless, tossing about the bed and much excited. I ordered acetanilid, 10 grains, at 9 a. m., and 5 grains thereafter, every three hours. After observing the patient for seven days, during which he had four seizures, all typically Jacksonian, followed by a slight transient weakness of the left leg, it was determined to make an exploratory operation. He was removed to the amphitheater August 31, anesthetized, and an oval incision made over the right parietal region, the bone having first been scored in order to mark the position of the Rolandic fissure; after the flap had been turned back, the trephine was then called into use and a button of bone removed over the region of the motor area for the left foot—before using the trephine there was noted a bluish line in or on the bone, running downward and forward almost parallel to about one-half inch behind the Rolandic fissure—the trephine opening was then enlarged downward and forward, and in the process there was opened a sort of venus sinus between the two layers of bone, and corresponding in situation to the blue line mentioned. The venus sinus had eroded the inner table of the skull, forming a cystic protuberance about the size of a bean. This caused a perforation of the dura mater—the dura for an area of two inches in diameter about this perforation was very much thickened and inflamed. On removing the body flap there protruded through the dura a sort of hernia of the pia and brain tissue. The dura was slit up in a crucial manner and both the dura and pia found much thickened and edematous; beyond this nothing was found, the cortex appearing normal. To arrest the hemorrhage from the venous sinus it was found necessary to introduce a sterilized match as a pug; this was left in the wound. Hemorrhage from other points was then arrested, the dura stitched together with interrupted gut-suture, the flaps of skin brought together with a continuous silk suture, and a plain gauze dressing applied.

On September 6 the stitches were removed. An examination of the special senses was negative. [illegible] first two days after the operation the patient was r[illegible] [illegible] and exacting, afterward was more liberal in [illegible] much more rational.

September 19. There were no [illegible] pronounced himself well.

September 26. He complained of [illegible] in the region of the knee-joint, w[illegible] plain; examination was negative. I[illegible] sations like [illegible] which used to p[illegible] He was or[illegible] d and 30 gra[illegible] were given [illegible]

October 8. [illegible] around at all.

October 17. [illegible] gen[illegible]

November 3. [illegible]

In December he returned for his epilepsy, saying that he had been free of attacks since the operation except two or three very light ones, neither of which were like his previous ones, and which he had been able to fight off. This morning, however, he had an attack exactly similar in every detail to those previous to the operation. He was given 15 grains potassium bromid. From this time until January there were no symptoms, no attacks and his condition was good. On August 25 he was discharged. On September 5 he returned to the hospital, saying that he had had an epileptic attack. He died at the County Infirmary about eighteen months after operation, during an epileptic attack.

In this case the recurrence of the epilepsy and the death of the individual were caused by the meningitis, which was set up by, and continued after, removal of the cyst.

CASE 4.—R. G., aged 10, colored, was admitted to Cincinnati Hospital May 20, 1895. The family and personal history were negative. There had been a gradual development of weakness and stiffness of the left arm and leg. This had lately increased to such an extent as to interfere with the use of the left arm altogether. The left leg was stiff and rigid and was dragged during walking; he had no pains in the extremity.

Examination gave the following: Mental condition was dull and apathetic; there was a tendency to somnolence. When aroused the mind was clear. Pupils were equal in size and reacted to light. Papilla was swollen and injected; there was choked disc. The external muscles of the eyes were normal in function. There was no defect in sensation of face or scalp; the left side of face—lower half—was paretic; the tongue protruded to the left. The left arm was rigid and spastic; the radial and triceps reflexes were increased; the muscular strength was reduced almost to a minimum; the size, the surface temperature and the sensation of arm were normal. The leg was normal in size and temperature; the muscles rigid and hard; the limb in condition of spasticity; the reflexes increased. There was ankle-clonus; muscular power was almost entirely lost; he was scarcely able to walk; dragged the leg, but the sensation normal. The diagnosis was spastic hemiplegia, subcortical brain tumor.

Dr. Ransohoff, after careful examination, decided to perform an exploratory operation. The diagnosis of subcortical tumor of the arm center of right side was made; the skull over this region was trephined, and a piece of bone about two inches in diameter was removed; the bulging of the brain and membranes was very marked, but on opening the dura the cortex of the brain was found intact. An incision was made through the cortex about an inch in length, but, as proved later, this was not made deeply enough. No tumor being found the wound was closed. Death occurred six hours later from shock. The autopsy showed a soft yellowish mass, fully the size of a hen's egg occupying the region of the nucleus lentiformis of the right side—it extended outward to within one-half inch of the cortex—extending upward into the region of the ascending frontal and parietal lobes, viz., the centrum semiovale; inward and downward it extended to the internal capsule. The microscopic examination showed the growth to be a tubercle.

The justification of the operation in this case lay in the fact that if the tumor could have been reached it might have been scooped out, and life could not only have been prolonged but have been made more endurable. That it could have been reached was shown by the autopsy. The growth was situated exactly under the trephine opening, and if the incision which was made in the cor[illegible]x had been a quarter of an inch deeper the tumor [illegible]ld have been found during life.

5.—F. B., aged 46, was hit by a flying brick on the left [illegible]is head. After being struck he boarded the electric [illegible]e to the foot of the steps leading to the Marine [illegible]e ascending these steps he fell down and was [illegible] hospital. Examination revealed nothing but [illegible]ver the temporal muscles, which was attend[illegible] surgeon.

He recognized his son one hour later, then became unconscious; he knew nothing of having been taken home, except that he inquired after his son, when put in wagon. After three days he recognized his son again. Two weeks later he recognized Dr. B., the attending physician. The first three days he did not say anything, then gradually regained his power of speech.

Examination showed his mental condition was good; memory good, but that he had lost knowledge of the names of objects; spoke in broken sentences because he could not remember words—knew what the object was but could not name it. This was more marked in his mother-tongue than in English, the knowledge of which is rather imperfect. He became excited under examination.

The eyes, face, tongue, extremities, pulse and temperature were normal. The head showed a depressed fracture under the temporal bone, circular in character, about the size of a dime—left side.

The treatment was iodid of potassium and protoiodid of mercury. An examination August 1, 1896, five months after the accident, showed that the patient had been growing worse gradually. He showed a great deal of absent-mindedness, and mental confusion. He loses himself; the speech defect has grown much worse; he is unable to repeat a word of two syllables. His mental condition is dull, sluggish and apathetic, almost stuperose. Speech is very much embarrassed. On August 3, 1896, he was operated on by Dr. E. W. Walker. The trephine was applied directly over the area of depression. The inner tables showed a cone-shaped depression of bone with the apex piercing both dura mater and pia mater and entering the cortex of the first temporosphenoidal convolution, cyst had formed about the apex of the depression and had attained the size of a small English walnut. There was no fever; the recovery was uneventful. Mental confusion, apathy, and dulness disappeared. Aphasia remained as it was. In May his condition was much better than immediately before the operation. In October, 1896, the aphasia was about the same; he could not repeat a long sentence. The right pupil was larger than the left; both responded to light. His mental condition was good.

May, 1900, the patient still had some sensory aphasia, but he spoke connectedly; carried on an ordinary conversation without much difficulty: had some trouble in remembering names, especially if the object was changed rapidly and an effort was made to hurry him.

There are two interesting features of his case: 1, the overlooking of the fracture of the skull by the first physician; 2, the apparent recovery, followed by symptoms of intracranial pressure. The first was due to the fact that the fracture was under the temporal muscle, which was not cut, the scalp wound extending down to the muscle-sheath; the muscles were probably contused and swollen, and it was very easy to overlook so small a fracture. The second feature, the rapid increase of all the signs and symptoms of intracranial pressure, during the fifth month, indicating brain tumor, except that there was no optic neuritis, was evidently due to the rapid increase in the size of the cyst—Bergmann calls attention to this feature of traumatic cysts.

Case 6.—J. M., a German plasterer, was admitted to Cincinnati Hospital May 30, 1898. He complained of convulsions of the left arm and leg, followed by anesthesia of affected areas, lasting about half an hour. His family history was negative. As a child he had measles, mumps, and scarlet fever. No venereal history was obtained; he chewed tobacco, and drank beer to excess till one year before his admission to the hospital. There was no drug habit.

About seven years before, while ascending a ladder, his left leg suddenly became helpless, causing him to make a mis-step, and he fell a distance of fifteen feet, but as he fell on a sofa he sustained no injury at the time. He did not lose consciousness, but immediately felt numb in the entire left half of the body; this feeling lasted about twenty minutes. After the numbness passed away he went to work feeling no ill effects. About one month later he was seized in the same manner and the attack lasted about the same length of time.

The attacks gradually increased in frequency till the fall of 1897, when he would sometimes have two attacks in one day.

Up to this time the patient was as strong as he ever had been; but had ceased to work at his trade two years previously for fear of falling and injuring himself. Attacks had become less frequent, so that none had occurred since February, except on April 19, on which day an attack occurred, preceded by bilateral clonic spasms lasting two or three minutes, followed by the usual left-sided numbness and weakness. All attacks previous to this one were preceded by unilateral clonic spasms of the left side lasting about two or three minutes. For the last six years the symptoms and attacks have occurred in about the following order:

1, full side headache lasting about twenty minutes; 2, vomiting, the vomitus consisting principally of bile; 3, dull aching pain over the right eye, lasting from five to twenty minutes; 4, tonic spasms of left arm and left leg; 5, numbness and weakness, lasting about thirty minutes.

Examination showed that his body was fairly well developed and nourished. He had a dull, rather languid expression of the face. His cerebration was somewhat slow, and he had a slight difficulty in talking.

Cranial Nerves.—First, normal; second, he could discern persons across the street, but could not recognize them; he could not read the newspaper at any distance; there was no aphasia. Optic neuritis was present; pupils reacted to light and accommodation; third, fourth and sixth were apparently normal; fifth, motor and sensory, normal; seventh, weakness of muscles of left side of face; ninth, tongue deviates to the left side; tenth, some difficulty in breathing in morning. Troubled considerably with hiccoughing; eleventh, on turning head to left, severe pain in right occipital lobe, similar pain in left lobe on turning head to right; twelfth, normal. There was some difficulty in swallowing. Motility, muscular power and grasp apparently normal and equal. Flexion, extension and power of right leg normal. Right leg was also affected at times, but only temporarily; often had passing weakness, rigidity and ankle-clonus. Unable to lift left leg from bed when extended, and when it was elevated can not flex nor extend it; resists bending somewhat, but no pain on bending. Left arm becomes exhausted easily; some inco-ordination; slightly weaker than right.

Gait.—Dragged left leg and foot; left arm hung almost motionless at side, although he had use of it; head inclined to the left side.

Sensation.—Pain, tactile, heat and cold, normal.

Reflexes.—Right and left knee exaggerated; right and left ankle-clonus marked; right and left wrist-jerk marked; right and left elbow-jerk marked.

Bladder.—He had frequent sensations of wanting to urinate, but had considerable difficulty in starting the stream. He sometimes voided urine before reaching the closet. Expelling force of bladder was much diminished. The rectum, lungs, heart, and urine were abnormal.

Exploratory trephining was done by Dr. Ransohoff over motor area of right side, but nothing found except much cerebral bulging. The patient died the same day from shock. The autopsy showed an oval opening about five inches by two and one-half inches in the parietal region of the right side, its lower margin about one and one-half inches above the external auditory meatus and the upper margin about one inch from sagittal suture. Just anterior to sagittal suture, about one inch in front and toward the median line from the opening in the calvarium, was an extensive thickening of the bone tissue circular in shape. At its central point, where it was thickest, the growth was about three-fourths of an inch thick. This thickening was due to the periosteal deposits, as the outlines of the calvarium could be plainly discerned directly under this thickening; dura mater was adherent to the brain.

The longitudinal sinus was obliterated by a soft semi-fluid, cream color growth. Under the dura mater was a growth about the size of a goose egg, which began on the surface about two inches from the tip of the first frontal convolution and extended backward along the longitudinal fissure to about two inches posterior to the fissure of Rolando.

The cortical size of this growth was about three and one-half by two and one-half inches, and occupied the posterior

July 30, 1894, the patient was re-admitted to the hospital. He admits having had gonorrhea but denies syphilis. Because of advisability of performing an operation his relatives were summoned and they gave a somewhat different history from the patient. The latter states that he has had attacks since the age of 7; his sister says that the attacks began in the twelfth year, three months after being struck on the back of the head with a brick. She states that he was brought into the city hospital unconscious, and was discharged in about a week. No record can be found. The examination of his head over the occiput reveals no scalp wound or depression of skull. The sister agrees with the patient as to the characteristic feature of the attack, that is, that it always begins in the left leg and extends to the left arm and face and then becomes general. She also says that he has attacks during which twenty-five to thirty convulsions occur in as many hours the patient often being unconscious during the entire period. During the last few days of August the patient complained of pain in the head. One night he had three convulsions, each lasting some minutes, and all characterized by muscular contractions beginning upon the left side. In the first one the left leg was flexed first. He slept soundly between the seizures. A fourth attack followed, the next morning. This was witnessed by the day nurses, and they say it was of the same general character as those described by the night nurse. Later the patient suddenly got out of bed and was caught in the act of jumping out of the window. He complained of great cephalalgia, was restless, tossing about the bed and much excited. I ordered acetanilid, 10 grains, at 9 a. m., and 5 grains thereafter, every three hours. After observing the patient for seven days, during which he had four seizures, all typically Jacksonian, followed by a slight transient weakness of the left leg, it was determined to make an exploratory operation. He was removed to the amphitheater August 31, anesthetized, and an oval incision made over the right parietal region, the bone having first been scored in order to mark the position of the Rolandic fissure; after the flap had been turned back, the trephine was then called into use and a button of bone removed over the region of the motor area for the left foot—before using the trephine there was noted a bluish line in or on the bone, running downward and forward almost parallel to about one-half inch behind the Rolandic fissure—the trephine opening was then enlarged downward and forward, and in the process there was opened a sort of venus sinus between the two layers of bone, and corresponding in situation to the blue line mentioned. The venus sinus had eroded the inner table of the skull, forming a cystic protuberance about the size of a bean. This caused a perforation of the dura mater—the dura for an area of two inches in diameter about this perforation was very much thickened and inflamed. On removing the body flap there protruded through the dura a sort of hernia of the pia and brain tissue. The dura was slit up in a crucial manner and both the dura and pia found much thickened and edematous; beyond this nothing was found, the cortex appearing normal. To arrest the hemorrhage from the venous sinus it was found necessary to introduce a sterilized match as a pug; this was left in the wound. Hemorrhage from other points was then arrested, the dura stitched together with interrupted gut-suture, the flaps of skin brought together with a continuous silk suture, and a plain gauze dressing applied.

On September 6 the stitches were removed. An examination of the special senses was negative. For the first two days after the operation the patient was restless, irritable and exacting, afterward was more liberal in his demands and much more rational.

September 19. There were no symptoms whatever, he pronounced himself well.

September 26. He complained of pain in the left leg, chiefly in the region of the knee-joint, which he was unable to explain; examination was negative. Patient said he had no sensations like those which used to precede an epileptic attack. He was ordered to bed and 30 grains of potassium bromid were given him.

October 8. He was up and around the ward; no symptoms at all.

October 17. No attacks at all; general condition good.

November 3. Discharged, well.

In December he returned for his epilepsy, saying that he had been free of attacks since the operation except two or three very light ones, neither of which were like his previous ones, and which he had been able to fight off. This morning, however, he had an attack exactly similar in every detail to those previous to the operation. He was given 15 grains potassium bromid. From this time until January there were no symptoms, no attacks and his condition was good. On August 25 he was discharged. On September 5 he returned to the hospital, saying that he had had an epileptic attack. He died at the County Infirmary about eighteen months after operation, during an epileptic attack.

In this case the recurrence of the epilepsy and the death of the individual were caused by the meningitis, which was set up by, and continued after, removal of the cyst.

Case 4.—R. G., aged 10, colored, was admitted to Cincinnati Hospital May 20, 1895. The family and personal history were negative. There had been a gradual development of weakness and stiffness of the left arm and leg. This had lately increased to such an extent as to interfere with the use of the left arm altogether. The left leg was stiff and rigid and was dragged during walking; he had no pains in the extremity.

Examination gave the following: Mental condition was dull and apathetic; there was a tendency to somnolence. When aroused the mind was clear. Pupils were equal in size and reacted to light. Papilla was swollen and injected; there was choked disc. The external muscles of the eyes were normal in function. There was no defect in sensation of face or scalp; the left side of face—lower half—was paretic; the tongue protruded to the left. The left arm was rigid and spastic; the radial and triceps reflexes were increased; the muscular strength was reduced almost to a minimum; the size, the surface temperature and the sensation of arm were normal. The leg was normal in size and temperature; the muscles rigid and hard; the limb in condition of spasticity; the reflexes increased. There was ankle-clonus; muscular power was almost *entirely lost; he was scarcely able to walk; dragged the leg*, but the sensation normal. The diagnosis was spastic hemiplegia, subcortical brain tumor.

Dr. Ransohoff, after careful examination, decided to perform an exploratory operation. The diagnosis of subcortical tumor of the arm center of right side was made; the skull over this region was trephined, and a piece of bone about two inches in diameter was removed; the bulging of the brain and membranes was very marked, but on opening the dura the cortex of the brain was found intact. An incision was made through the cortex about an inch in length, but, as proved later, this was not made deeply enough. No tumor being found the wound was closed. Death occurred six hours later from shock. The autopsy showed a soft yellowish mass, fully the size of a hen's egg occupying the region of the nucleus lentiformis of the right side—it extended outward to within one-half inch of the cortex—extending upward into the region of the ascending frontal and parietal lobes, viz., the centrum semiovale; inward and downward it extended to the internal capsule. The microscopic examination showed the growth to be a tubercle.

The justification of the operation in this case lay in the fact that if the tumor could have been reached it might have been scooped out, and life could not only have been prolonged but have been made more endurable. That it could have been reached was shown by the autopsy. The growth was situated exactly under the trephine opening, and if the incision which was made in the cortex had been a quarter of an inch deeper the tumor would have been found during life.

Case 5.—F. B., aged 46, was hit by a flying brick on the left side of his head. After being struck he boarded the electric car and rode to the foot of the steps leading to the Marine Hospital; while ascending these steps he fell down and was carried into the hospital. Examination revealed nothing but a scalp wound, over the temporal muscles, which was attended to by the resident surgeon.

He recognized his son one hour later, then became unconscious; he knew nothing of having been taken home, except that he inquired after his son, when put in wagon. After three days he recognized his son again. Two weeks later he recognized Dr. B., the attending physician. The first three days he did not say anything, then gradually regained his power of speech.

Examination showed his mental condition was good; memory good, but that he had lost knowledge of the names of objects; spoke in broken sentences because he could not remember words—knew what the object was but could not name it. This was more marked in his mother-tongue than in English, the knowledge of which is rather imperfect. He became excited under examination.

The eyes, face, tongue, extremities, pulse and temperature were normal. The head showed a depressed fracture under the temporal bone, circular in character, about the size of a dime—left side.

The treatment was iodid of potassium and protoiodid of mercury. An examination August 1, 1896, five months after the accident, showed that the patient had been growing worse gradually. He showed a great deal of absent-mindedness, and mental confusion. He loses himself; the speech defect has grown much worse; he is unable to repeat a word of two syllables. His mental condition is dull, sluggish and apathetic, almost stuperose. Speech is very much embarrassed. On August 3, 1896, he was operated on by Dr. E. W. Walker. The trephine was applied directly over the area of depression. The inner tables showed a cone-shaped depression of bone with the apex piercing both dura mater and pia mater and entering the cortex of the first temporosphenoidal convolution, cyst had formed about the apex of the depression and had attained the size of a small English walnut. There was no fever; the recovery was uneventful. Mental confusion, apathy, and dulness disappeared. Aphasia remained as it was. In May his condition was much better than immediately before the operation. In October, 1896, the aphasia was about the same; he could not repeat a long sentence. The right pupil was larger than the left; both responded to light. His mental condition was good.

May, 1900, the patient still had some sensory aphasia, but he spoke connectedly; carried on an ordinary conversation without much difficulty; had some trouble in remembering names, especially if the object was changed rapidly and an effort was made to hurry him.

There are two interesting features of his case: 1, the overlooking of the fracture of the skull by the first physician; 2, the apparent recovery, followed by symptoms of intracranial pressure. The first was due to the fact that the fracture was under the temporal muscle, which was not cut, the scalp wound extending down to the muscle-sheath; the muscles were probably contused and swollen, and it was very easy to overlook so small a fracture. The second feature, the rapid increase of all the signs and symptoms of intracranial pressure, during the fifth month, indicating brain tumor, except that there was no optic neuritis, was evidently due to the rapid increase in the size of the cyst—Bergmann calls attention to this feature of traumatic cysts.

Case 6.—J. M., a German plasterer, was admitted to Cincinnati Hospital May 30, 1898. He complained of convulsions of the left arm and leg, followed by anesthesia of affected areas, lasting about half an hour. His family history was negative. As a child he had measles, mumps, and scarlet fever. No venereal history was obtained; he chewed tobacco, and drank beer to excess till one year before his admission to the hospital. There was no drug habit.

About seven years before, while ascending a ladder, his left leg suddenly became helpless, causing him to make a mis-step, and he fell a distance of fifteen feet, but as he fell on a sofa he sustained no injury at the time. He did not lose consciousness, but immediately felt numb in the entire left half of the body; this feeling lasted about twenty minutes. After the numbness passed away he went to work feeling no ill effects. About one month later he was seized in the same manner and the attack lasted about the same length of time.

The attacks gradually increased in frequency till the fall of 1897, when he would sometimes have two attacks in one day.

Up to this time the patient was as strong as he ever had been; but had ceased to work at his trade two years previously for fear of falling and injuring himself. Attacks had become less frequent, so that none had occurred since February, except on April 19, on which day an attack occurred, preceded by bilateral clonic spasms lasting two or three minutes, followed by the usual left-sided numbness and weakness. All attacks previous to this one were preceded by unilateral clonic spasms of the left side lasting about two or three minutes. For the last six years the symptoms and attacks have occurred in about the following order:

1, full side headache lasting about twenty minutes; 2, vomiting, the vomitus consisting principally of bile; 3, dull aching pain over the right eye, lasting from five to twenty minutes: 4, tonic spasms of left arm and left leg; 5, numbness and weakness, lasting about thirty minutes.

Examination showed that his body was fairly well developed and nourished. He had a dull, rather languid expression of the face. His cerebration was somewhat slow, and he had a slight difficulty in talking.

Cranial Nerves.—First, normal; second, he could discern persons across the street, but could not recognize them; he could not read the newspaper at any distance; there was no aphasia. Optic neuritis was present; pupils reacted to light and accommodation; third, fourth and sixth were apparently normal; fifth, motor and sensory, normal; seventh, weakness of muscles of left side of face; ninth, tongue deviates to the left side; tenth, some difficulty in breathing in morning. Troubled considerably with hiccoughing; eleventh, on turning head to left, severe pain in right occipital lobe, similar pain in left lobe on turning head to right; twelfth, normal. There was some difficulty in swallowing. Motility, muscular power and grasp apparently normal and equal. Flexion, extension and power of right leg normal. Right leg was also affected at times, but only temporarily; often had passing weakness, rigidity and ankle-clonus. Unable to lift left leg from bed when extended, and when it was elevated can not flex nor extend it; resists bending somewhat, but no pain on bending. Left arm becomes exhausted easily; some inco-ordination; slightly weaker than right.

Gait.—Dragged left leg and foot; left arm hung almost motionless at side, although he had use of it; head inclined to the left side.

Sensation.—Pain, tactile, heat and cold, normal.

Reflexes.—Right and left knee exaggerated; right and left ankle-clonus marked; right and left wrist-jerk marked; right and left elbow-jerk marked.

Bladder.—He had frequent sensations of wanting to urinate, but had considerable difficulty in starting the stream. He sometimes voided urine before reaching the closet. Expelling force of bladder was much diminished. The rectum, lungs, heart, and urine were abnormal.

Exploratory trephining was done by Dr. Ransohoff over motor area of right side, but nothing found except much cerebral bulging. The patient died the same day from shock. The autopsy showed an oval opening about five inches by two and one-half inches in the parietal region of the right side, its lower margin about one and one-half inches above the external auditory meatus and the upper margin about one inch from sagittal suture. Just anterior to sagittal suture, about one inch in front and toward the median line from the opening in the calvarium, was an extensive thickening of the bone tissue circular in shape. At its central point, where it was thickest, the growth was about three-fourths of an inch thick. This thickening was due to the periosteal deposits, as the outlines of the calvarium could be plainly discerned directly under this thickening; dura mater was adherent to the brain.

The longitudinal sinus was obliterated by a soft semi-fluid, cream color growth. Under the dura mater was a growth about the size of a goose egg, which began on the surface about two inches from the tip of the first frontal convolution and extended backward along the longitudinal fissure to about two inches posterior to the fissure of Rolando.

The cortical size of this growth was about three and one-half by two and one-half inches, and occupied the posterior half of the first and second frontal convolutions and the upper half of the ascending frontal and ascending parietal convolution around the fissure of Rolando and backward into the gyrus angularis. It bulged into the longitudinal fissure and pressed on the median surface of the psychomotor area of the left side.

Subcortically, it extended into the corona radiata, pressed on and destroyed the posterior portion of the lenticular nucleus and the fibers of the internal capsule. The cortex above the tumor was entirely obliterated, whereas the cortex of the lower portion of the psychomotor area and the portion of the corona radiata beneath it was intact.

The tumor was soft and fluctuating On section it was semisolid, very soft, creamy in color and rather vascular. After being hardened it proved to be non-infiltrating, and could be shelled out with ease. Microscopic examination proved the tumor to be a gliosarcoma.

The interesting features of this case are: The long duration of the tumor's growth—seven years elapsing between the onset of the first symptoms and the death of the individual. Death was due to shock of the operation, and life might have been prolonged for some time. This feature alone is interesting in a therapeutic sense, because the hardened brain specimen shows that the tumor could have been shelled out if the calvarium had been opened just over it; the difficulty lay in the proximity of the growths to the longitudinal fissure. It proves once more that growths of long duration are more apt to compress the brain matter than to infiltrate the brain substance, and that, therefore the operative success is more promising than in those of more rapid growth. The second peculiarity is the presence of bilateral symptoms, viz., the frequent variation of the involvement of the right side of the face—a condition which can probably be explained only on the basis of varying pressure of the tumor on the corona radiata of the left side of the cerebrum and then the change—the involvement of the right leg and foot—the presence of spastic paresis and ankle-clonus at one examination and their absence at the next. These variations of symptoms were easily explained at the autopsy, but during life were a source of continual doubt as to whether the tumor was cortical or basal. The presence of the tumor mainly in the lobus paracentralis of the right psychomotor area, pressing upon the lobus paracentralis of the left psychomotor area, explains the bilateral spastic symptoms; and the variability of the symptoms were, in all probability, due to the increase and diminution of the vascularity of the growth. It is a little strange that the growth, by irritation, never produced an attack of localized epilepsy in the right foot.

Case 7.—C. R., was admitted to Cincinnati Hospital July 12, 1899, in a state of coma. A friend stated that he was subject to epileptic fits, and during an attack fell backward down six steps and struck on the back of his head. He could be aroused, and answered questions, volunteered no statement, resisted attempts at examination; vomited greenish fluid; had use of all his limbs; tried to walk, but had to be supported; complained of back of neck hurting him.

Examination.—His head showed no evidence of injury. The pupils were dilated, left more than right; no reaction to light. The conjunctiva was injected; the tongue was coated and furrowed longitudinally, and protruded in the median line. He resisted all attempts at movement of his extremities, but could move them at will.

Reflexes were all increased on the left; right negative. Muscular power was decreased, much more on the left. Sensation was normal. The urine was small in amount, pea-green in color, and contained a small amount of albumin.

July 13.—Coma deeper, respiration stertorous; could still be aroused. Left side, both arm and leg were in a state of spastic rigidity. No voluntary movements in arm or leg of this side; right arm and leg were normal. Pupils were moderately contracted, and did not react to light. Urine was passed involuntarily. At 6 p. m. he could not be aroused. His mouth was drawn to the left. Reflexes were lost on the left side; no voluntary movement of this side. Arm and leg were rigid. Reflexes on the right side were greatly exaggerated. He was very restless, constantly moving right arm and leg. There was Cheyne-Stokes respiration; mucous râles could be heard all over the chest. His temperature was 103 degrees, and his pulse rapid and irregular. Operation was performed at 11:30 a. m.; the fissure of Rolando right side was marked off and trephine opening made over lower extremity. There was no fracture; no extradural hemorrhage, and very slight pulsation of the brain. The brain opening was enlarged and an incision made in the dura, followed by a gush of partially clotted dark blood. Brain tissue immediately protruded into the wound, was dark and congested and at lower angle of wound showed areas of softening about one by three-fourths of an inch. Blood welled up from the opening for a time, containing brain tissue. The wound was gently cleansed with warm water, and dura partially closed with catgut, the opening being left over soft area, small rubber drainage-tube placed in cavity, and drain of silkworm gut externally and scalp sutured, leaving good-sized opening for drainage at lower angle of wound.

When dura was opened the clot removed, and the anesthetic discontinued, spastic condition of the left side disappeared and voluntary movement was possible and rather freely performed. This soon disappeared and patient relapsed into former condition. After removal to the ward condition gradually became worse and patient died without regaining consciousness at 2 p. m., July 15, 1900.

The post-mortem showed no evidence of external violence. There was extensive hyperemia of both hemispheres. Punctate hemorrhages were seen over—ten or twenty in number—the surface of both hemispheres from the size of a pin head to that of a split pea. On the tip of the frontal convolution of both sides there was an infiltration of blood on the surface the size of a dime; on section these bloody surfaces were found to cover a cyst about as large as a hazelnut; there was clotted blood in the middle fossa. Over temporosphenoidal and running anterior to knee of fissure of Sylvius was a large blood clot. The cortex below was extensively destroyed with opening leading into large cavity the size of a hen's egg. This cavity extends down to and involves the internal capsule. In parts of the wall the cyst shows black spots, size of pin head; other parts red; posterior portion of cavity, the cortex is destroyed and replaced by a soft and granular mass. This infiltration extends for considerable area around cortical margin of cyst, replacing normal cortex. Major portion of cortex surrounding cavity is softened, probably acute softening from hemorrhage destruction. Five other cysts were found on surface of both hemispheres; one on tip of each frontal lobe. The others were over the parietal lobes and the temporosphenoidal. These varied in size from a bean to a hazel nut. They are covered with pia mater. On opening them the cavity is conical in shape and the apex is formed by a small round hard mass, laminated and dark brown in color; the cortex is destroyed and the contents yellowish-red in character.

In various regions the pia is adherent, and a granular mass extends from its under surface into the cortex, being continuous, and apparently infiltrating the latter. The basilar ganglia, interpeduncular space, medulla, cord and bridge, show no gross anatomical changes.

Close inquiry among the friends elicited the information that the patient had had about six epileptic seizures in the past year, and had been perfectly well before. He had always been at work, and was taken with his last epileptic seizure during a night of dissipation in a house of ill-fame. No other history could be elicited. No history of syphilis, and with the exception of the epileptic seizures, he enjoyed the best of health and did not consider himself sick.

Before the operation, having no previous history of the case, it was thought that the fall produced a subdural hematoma, and the finding of the numerous hemorrhagic cysts was quite unexpected. The epilepsy undoubtedly was caused by the presence of these cysts, and the fatal hemorrhage was undoubtedly the result of a rupture of one of these cysts, superinduced by the fall on the back of the head.

When we look over the tables of published operative cases which have been collected from the world over, we are struck with the small number of cases. The brain is a favorite seat of tumors and we all know how frequently they occur.

Bergmann, basing his opinion on an analysis of Hale White's 100 cases of brain tumors, found in the autopsy room of Guy's Hospital, Seydel's 50 cases, Allen Starr's 600 cases, compiled from all sources, and Oppenheim's 23 cases, all carefully observed *intra vitam* and after death, comes to the conclusion that at most but from 6 to 7 per cent. of all brain tumors can form the subject for surgical interference, and that to all intents and purposes brain surgery, with rare exceptions, resolves itself into the surgery of the psychomotor areas. We should not be discouraged, however, by the result of this analysis, but should be spurred on to greater exertions, to greater efforts in singling out the favorable cases. I can do no better than quote Bergmann again: "Among the tumors which grow in the cortex and can, therefore, be reached by the knife, those are most frequently present which promise favorable results from an operation, viz., tough fibromata and sarcomata, which are well encapsulated, have their seat of predilection in the gray matter of the cortex, and when once removed do not seem to recur. Even the most benign brain tumor is a fatal disease, for it grows without a halt, and it is this very growing which threatens to destroy the mental as well as the physical life of the patent. There is but one way to put a stop to this growth, the timely removal of this dangerous, although histologically benign tumor." Considering the necessarily fatal result of this trouble, results of the surgical interference are not bad. Its future lies in the hands of the neurologist and not the surgeon. For the most important point in brain surgery is the accuracy of the diagnosis and localization. This is illustrated by the comparison of the statistics collected by Von Hippel and published in Bergmann's latest work on brain surgery. Von Hippel collected all the published operations on the brain and these can be divided into two groups: 1. Those cases in which the brain tumor or cyst was accurately located and removed; 2, those in which the localization was defective and the so-called exploratory operation was made. The first group comprises 116 cases; in all of them the tumors were removed and 60 per cent. of the cases were decidedly improved or cured, and only 7 per cent of the cases were not benefited at all or died as a result of the operation.

No.	Name, Sex, Age.	Operator.	First Symptom.	Local Symptoms.	General Symptoms.	Optic Disc.	Operation.	Seat of Tumor.	Result.
1	Mr. L.; 32	Ransohoff; Hoppe.	Jackson epilepsy.	Jackson epilepsy of l. arm and leg.	Generalized convulsions, headache, vertigo	*Negative.*	*Trephining*	*Right foot and arm center*	Hemiplegia; epilepsy; still alive: seven years.
2	T. B.; male: 18	R. Sattler; Hoppe.	Hemianopsia	Total blindness.	Headache, vertigo, nausea	Pale.	Trephining	Left occipital lobe	Recovery of sight; still alive; seven years.
3	A. G.; male; 22	John Oliver; Hoppe.	Jackson epilepsy	Epilepsy; *epileptic insanity.*	*None*	*Negative.*	Trephin*ing*	Cyst over right leg center	Improvement for 6 mos.; died after one year.
4	R. G.; male; 10	Ransohoff; Hoppe.	Spastic par'sis of left arm.	Spastic hemiplegia	Headache, apathy	Choked disc.	Trephining	Subcortical motor area. Right side	Died in four hours; shock.
5	F. B.; male; 46	E. W. Walker; Hoppe.	Sensory aphasia	Sensory aphasia.	Headache, mental confusion	Negative.	Trephining	Cyst of 1st temp. *sphen.* lobe. Left side.	Much improved for sensory aphasia; still alive.
6	J. M.; male: 32	Ransohoff; Hoppe.	Numbness; weakness of left leg	Jackson epilepsy; hemiplegia; diplegia.	Headache, vertigo, apathy	Choked *disc.*	Trephining	Right foot center.	Died from shock in four hours.
7	C. R.; male; 23	Ransohoff; Hoppe.	General epilepsy	Spastic hemiplegia	Coma, convulsions	Negative.	Trephining	Multiple cysts	Died from cerebral hemorrhage.

The condition, however, is entirely different in the so-called exploratory operations or in those cases in which, although the tumor was found, it was too large for removal. There were 157 of these cases and the operations were either useless or worse, for 47.7 per cent. died as the direct result of the operation. If all the unsuccessful cases were reported, I am quite sure that the number of cases in Class 2 would be increased by several hundred, and the mortality percentage of the operation would be still greater. There is but one lesson to be learned from these statistics, and it is, if you can not localize your tumor do not operate. There is only one possible condition which can suspend the operation of this rule and that is palliative trephining for the relief of unbearable intracranial pressure, when we fail to obtain relief by the Quincke puncture.

The main obstacle which lies in our path of success is the difficulty of diagnosis and accurately locating the tumors and cysts. These difficulties are nowhere set forth in a clearer light than in Prof. H. Oppenheim's address delivered before the joint session of Neurology and Surgery at the International Congress held in Moscow in 1897. Speaking of brain surgery he says: "The whole subject is still in the developmental stage, a subject of future solution and in only a few places can we make a sharp distinction between that which is true, solid and enduring, and the counterfeit and evanescent. We have become calm and sober because we realize that we stand on uncertain ground and that of the fruits for which we strive scarcely a single one has ripened. The rocks on which the hopes of surgery of the brain have been shattered in the past have not been a defective technique nor the inherent danger of attacking the brain, but the uncertainty of diagnosis." What was true in 1897 still holds to-day. Although the advances made have been great, we are still far from standing on solid ground in brain localization. This is partly due to the inherent difficulty of the subject and partly due to a sufficient lack of pathologic data. This difficulty of accurate localization even when the lesion clearly points to the psychomotor area is clearly illustrated by two of the above cases, viz, 6 and 4. In Case 6, on account of the variation of the signs and development of bilateral involvement, it was, for a long time. almost impossible to locate the tumor. It was first thought that the tumor was at the base of the brain. The marked character of the epileptic seizure led us to open the calvarium over the left leg center, near the arm center. No tumor was found; the autopsy, however, cleared up the diagnosis and explained the difficulty. The tumor was in the right lobus paracentralis; the involvement of the right leg was due to the pressure of the tumor on the lobus paracentralis of the left side, the fluctuation in the involvement of the face and tongue was caused by the extension of the tumor into the centrum semiovale and the pressure —distant—upon the internal capsule.

If it had been possible to locate the tumor accurately, the operation would probably have been successful, for the hardened brain showed that the tumor could have been enucleated. Case 4 offers a similar difficulty of accurately locating tumors of the psychomotor areas. The diagnosis of subcortical tumor of the arm center was made, but it was impossible to say how near the tumor was to the cortex or how near it was to the internal capsule. But viewed in the light shed upon the subject by the autopsy we can say that the preponderance of the spastic signs over the paretic and the entire absence of Jacksonian epilepsy should have shown us that the tumor was near the internal capsule, and should have been subject to an operation.

For more detailed accounts of the difficulties of diagnosis and localization, and distinguishing tumors [illegible] frontal lobe from those of the cerebellum, of the parieteal and occipital lobes, I would refer the reader to recent publications of Fritch and Hitzig, Knapp, Hermanides, Oppenheim, Bruns, etc.

The following are the conclusions which most authorities have come to, as a result of the observation of their own cases and the study of the literature on the subject:

1. Tumors of the cortex or subcortical region of any portion of the cerebral hemispheres which can be reached through the calvarium are operable.

2. If possible the operation should be performed early, when the tumor is small; but even large tumors and those infiltrating in character, have been operated on with success.

3. A study of the successful cases shows that, with few exceptions, brain surgery is limited to the psychomotor areas (Von Bergmann).

4. The result of surgical interference even in the most successful cases, rarely leads to complete recovery. The general symptoms due to intracranial pressure disappear, but the focal symptoms, viz, the epileptic seizures and paralysis, either remain permanently or are only diminished. It must not be forgotten, however, that the life of the individual has been saved.

5. Cerebellar tumors are inoperable. This is the law laid down by Oppenheim and concurred in by Bergmann. Those of the posterior and upper surface of the cerebellum, near the lower margin of the occipital lobe have been removed, but the operation has been invariably fatal (Oppenheim). The danger is due to the crowding of large sinuses into a small field of operation and the pressure upon, and displacement of, the medulla. Occasionally a cyst has been luckily tapped, but we can never localize with certainty, and we all know how disastrous exploratory operations are in this region.

6. The cumulative experience of all writers is against the exploratory operation.

7. Shall we advise palliative operations? On this subject authority is divided. Horsley, Bramwell, Annandale, Sanger, Sahli, Sinking, Keen, Bruns, and perhaps Oppenheim are in favor of palliative operations for the relief of violent symptoms of increased intracranial pressure in rare cases. Von Bergmann and Von Braman are against it. My limited experience in cases in which I refused to advise an operation and the operation was, nevertheless, performed, has been with those who oppose the operation.

8. I do not agree with Oppenheim that gummata should not be operated on. I have in my possession the brain of a man who refused to be operated upon which shows that the gumma could have been removed successfully. This gumma was located accurately and diagnosed as such in the arm center during life. In my opinion, tubercles, if isolated and located so as to be operable, should be operated upon, other things being favorable. Metastatic carcinomata are inoperable.

DISCUSSION.

Dr. Daniel R. Brower, Chicago—Dr. Hoppe's paper quite harmonizes with the Chairman's admirable address, and emphasizes the fact that we do cure some patients. This question of brain tumor is one of exceeding interest, but I am free to confess than in my experience I have not had as favorable results as Dr. Hoppe reports. While I have in some cases seen temporary benefits follow operation, and while I am sure I shall continue to recommend operations, I have yet to see in my own clientage a recovery. The differentiation of a cortical from a subcortical is usually impossible. A short time ago a case presenting all the classical symptoms of tumor in the motor area, was referred to Prof. N. Senn for operation; he failed to find the tumor, but post-mortem examination found it, a gumma, as was supposed, just beneath the cortex.

Dr. Charles H. Hughes, St. Louis, Mo.—I think the position taken by the essayist is eminently correct. The subject of cerebral tumors, especially the tumors involving the optic area of the brain, is particularly interesting. I would like to see more records of the ophthalmological evidences in these cases for diagnostic purposes. I saw a case before the New York Neurological Society, on my return from Europe last year. in which the diagnosis hinged on the neuroretinitis. or choked disk, and I believe I have never seen such a case of tumor which did not reveal the retinal symptoms. This, of course. is merely my own personal experience. The first case of brain tumor that I ever operated on was a great many years ago. and I found the tumor in the area that showed negatively how valuable the recent discoveries were in regard to the psychomotor areas of the brain. The next operation was performed before the subject of aphasia was so thoroughly understood. and was the case of a patient who became an automaton; he lost the capacity of speech, and it was only necessary to give him a start and he would walk from one end of the corridor to the other. After the operation the patient began to speak, and became annoyingly loquacious.

Dr. William G. Spiller, Philadelphia—Dr. Hughes' remarks on the presence of optic neuritis in brain tumor lead me to speak of two cases I have recently observed. One was a case reported by Dr. C. K. Mills; I saw the patient with Dr. Mills a number of times, and in that case there was no optic neuritis. The tumor was removed, and the patient improved very much after the operation. In a case that has been under my care recently, optic neuritis played a very important rôle in diagnosis. The patient was sent to me with symptoms of disease of the spinal cord, in the upper cervical region; she had stiffness of the neck, so that the head could be only slightly moved in any direction, and had other symptoms of tumor in the cervical region. I sent her to Dr. Hansell for an examination of her eyes, and he found that she had a high-grade neuritis in each eye. That was the only cerebral symptom she had, except loss of smell. The optic neuritis in this case led me to believe that probably the tumor was not confined to the vertebral canal. I found at the necropsy a tumor in the upper part of the cervical region, which had gradually grown downward and pressed on the cervical cord, and had extended to the third or fourth cervical segment. but had not involved the cord except by compression. The tumor extended upward along the base of the brain and covered the medulla oblongata and pons.

Dr. A. E. Sterne, Indianapolis—I have recently had rather a considerable number of operations, for, as you know, they frequently come together. In the first two weeks of March I had five operations on the brain. Some time in February of this year I lost a case through what I thought to be neglect on the part of the attendants at one of our hospitals in Indianapolis, a case which I had every reason to believe would recover. Dr. Hoppe's mention of the word "shock" recalls the case to me, as I have lost no case since I have made it an invariable rule to count shock as a part of the operation. I expect shock to follow; I do not wait until it comes. If there has been any degree of loss of blood, as there usually is in these cases, I feel almost sure that I am going to have shock, and I feel sure that we will have a rise of temperature up to 105; that is the rule, although it has frequently been supposed to be a fatal symptom. Before the patient comes from under the effect of the narcotic I have invariably given a saline infusion, and sometimes in addition to that a large enema, adding hypodermics of strychnia, in one case as high as 1/40 grain every ten minutes, keeping this up for the first twenty-six hours, and giving smaller doses thereafter. In that case the patient recovered, although, of course, it seemed a huge amount of strychnia to use. In all the subsequent cases I have had no ill results, and the last seven cases have all recovered. Of course, so far as concerns the final results of those cases, the time is as yet too short to decide; two were for tumors, two for cysts, and three were for conditions of idiocy. In the last three cases the idiocy was combined with spastic symptoms of a motor nature, and almost the entire top of the skull was removed, making a trephine opening on one side and a trephine opening on the other, joining in a circular fashion. No evil results whatever have occurred. I warned the family that they could not expect results immediately, and possibly not for several years, and I believe that precaution should always be taken.

I find that surgeons, as a rule, who are not neurologists are afraid to go deeply into the brain. There is no reason why they should not go deeply. We operate on internal hydrocephalus; why can we not go deeply into the brain at any time, always, of course, with the certainty in mind that a few symptoms in the motor area will follow? Owing to the fact that you have cut into the motor area there is usually a slight paresis remaining. So far as choked disk is concerned, it seems to me that optic symptoms are much more apt to be present in tumor. Cysts and abscesses do not produce choked disk in my experience nearly so often as the tumors, even when the tumors are of much less extent. Probably this is due to the greater consistency of brain tumors in comparison to the other lesions, and, therefore, the intracranial pressure will be the higher.

Dr. Maximilian Herzog, Chicago—I have been interested for some time in the subject of brain tumors from the standpoint of the pathologist, and I want to make a plea for a more exact classification of brain tumors. I think that blood cysts, and other cysts not true neoplasms in their nature, should not be included when we speak of brain tumors. Even if we find certain common clinical features we are not entitled to treat conditions so fundamentally different under the same heading. The books generally contain the statement that sarcomata are the most common neoplasms of the central nervous system. I am, from my own observations, inclined to doubt this statement, and I believe that gliomata are the most common tumors of the central nervous system. Dr. Hoppe reports among his cases one operated on, and well three years after the operation, as a sarcoma. I somewhat doubt the correctness of the pathologic diagnosis; I rather believe that this tumor was a glioma. It is sometimes not at all easy to make a correct histologic diagnosis of tumors of the brain, hence formerly many were diagnosed as glio-sarcoma, a classification which has been abandoned entirely for obvious reasons.

Dr. H. H. Hoppe, in closing—The autopsy in this case showed that the tumor was much closer to the internal capsule than it was to the cortex. If the tumor is close to the cortex there is no reason why there should not be optic neuritis. As to Dr. Herzog's views with regard to sarcoma, I would say that the diagnosis was made in this case by a pathologist. On the other hand, I have quoted in my paper a statement by Bergmann about sarcoma. There was one point that was not raised, and that is the question of diagnosis and its bearing on the results. Karl von Heller has tabulated all the published brain-tumor operations, and they are given again in Bergmann's book on "Brain Surgery." There are 116 cases of successful removal of brain tumors, and in these cases each tumor was localized before the operation; in over 60 per cent. of these cases were the patients benefited, and in only 7 per cent. was the death due to the results of the operation. On the other hand, there are 259 cases of so-called explorative cases, and in these 50 per cent. died as the result of shock. The point is, that if you can not localize your tumor you should not operate. The great point in brain surgery to-day is the accuracy of localization of the tumor before operation.

THE SKULL AND ITS CONTENTS.*

W. H. EARLES, B.Sc., M.D.

Professor of Surgery and Clinical Surgery, Milwaukee Medical College; Surgeon to Trinity Hospital and Milwaukee County Hospital; Consulting Surgeon to Emergency Hospital and Milwaukee Free Dispensary.

MILWAUKEE, WIS.

If the expression sometimes ascribed to Sir Astley Cooper, that "No injury of the head is too slight to be despised nor too severe to be despaired of," be true, I will need no apology for inviting attention to the subject, except perhaps for the weakness of its presentation. Injuries to the head should possess, for every practitioner, more than ordinary interest, as they entail more than ordinary responsibilities, and when we consider the many and varied conditions met with in this field of surgery, from the slight and apparently trivial scalp wound to the fracture of the base of the skull with its probable accompanying laceration of brain tissue and membranes, and possibly rupture of large blood-vessels, the range of thought necessary to comprehend and combat these conditions becomes apparent.

In the contemplation of this class of injuries we may say, in a general way, that the practitioner must ever keep in mind not alone the skull, but its coverings and contents, as well as the intimate relations existing between them, for even a slight scalp wound, if neglected, may terminate fatally, and what appears to be only a trivial blow on the head may produce fatal cerebral hemorrhage. We must, therefore, be prepared for any reasonable probability or possibility and must by the exercise of forethought and intelligently applied treatment strive to secure satisfactory *immediate* results and prevent undesirable *remote* ones. The anatomic position of the head being one of special and almost constant exposure to violence predisposes to a large number of injuries. The delicate nature of the skull contents predisposes to the gravity of these injuries, while the intimate relations existing between the coverings and contents of the skull, although apparently separated by a closed, bony wall, teach us that injury to the former predisposes to disease of the latter and should teach us how prudent it will be on our part to guard against possible unfortunate results by prompt and intelligent action. The natural openings which lead to the interior of the skull, while in their normal condition and undisturbed by traumatism, serve the purposes of their existence without imperiling the integrity of neighboring structures, but when once seriously interfered with they become dangerous channels through which infection may and often does reach the structures lying within the skull wall. Thus it will be seen that nature's necessities predispose to gravity in any injury to the head.

---

* Presented to the Section on Surgery and Anatomy, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

Nature has, however, made many admirable provisions to counteract, as far as may be, the unfortunate though necessary conditions above described. The skull is not only covered by the pericranium and tough resisting scalp, but is also carefully lined for the better protection of its contents, the importance of which protection daily experience demonstrates. The shape of the skull, as well as the varying degrees of thickness which it presents at different points and in different individuals, must necessarily enter into all calculations as to the possible or probable injury to the parts lying immediately within its walls when subjected to violence. The elasticity and resiliency of the skull bones are factors sufficiently important in themselves to merit close study. The especially ingenious and practical arrangement of the anatomy of the skull, giving as it does the best possible protection to its contents consistent with limited weight and general utility, is another of nature's provisions for the protection of its own creation. In brief, the shape, physical characteristics, coverings and lining are so well adapted to resistance and protection that ordinary violence results in but slight injury, usually confining itself to the scalp and external soft parts and not extending to the bony wall or its contents.

The skull has, however, in common with other parts of the body, its limit of resistance, and when this has been overcome a multiplicity of pathologic conditions become possible. These conditions will demand, on the part of the surgeon, an intimate knowledge not alone of the normal appearances of the parts involved, but also of the possible or probable pathologic conditions resulting from any given injury, for on this knowledge —on the accuracy with which the surgeon can estimate the nature and degree of the effects of the traumatism —must depend in a large measure his success or failure in treatment. We know that, apparently contrary to general law, a slight blow on the head is sometimes followed by the most serious results, and vice versa, and we should also know as surgeons that there must be reasons for these strange results, and these reasons must be sought for, utilized, and made a part of the clinical history of each case. It is a well-known fact that a blow on the head may produce any one of a variety of fractures with or without injury to the brain, its coverings or circulation. The outer plate of bone may be broken without the inner being affected, and the latter may be fractured without the presence of any apparent or actual depression in the outer one. The writer met with a case, in 1895, where the postmortem revealed a fracture of the inner plate of the skull 1½ inches in length, great laceration of brain tissue with rupture of the middle meningeal artery, and yet there was not even a scalp wound nor any evidence on the outer surface of the bone to indicate in the slightest degree the character and extent of the injury within. As a rule, however, when fracture exists both plates are involved. When an injury is present it is usually found at or near the part at which the force has been received, although there are occasional exceptions. Whenever there exists an injury of sufficient severity to have lacerated the brain or its membranes, hemorrhage resulting in clot, or more rarely, inflammation resulting in exudate follows. In either case the cranial contents are increased in volume and, as the skull walls are unyielding, pressure on the brain is a natural and inevitable consequence. This pressure, limited at first, is likely to increase until the brain functions are seriously interfered with or until life itself is extinct. The altered and abnormal conditions within the cranium may result in but temporary and trivial altered nerve manifestations, or they may result in partial or complete abolition of the motor, intellectual or sensory brain functions.

It is reasonably safe to be guided by the rule that intracranial pressure, when mild and local in character, will result in but mild and local functional disturbances, but when the pressure becomes general through the extension of the clot or the exudate all functional disturbances become general or the pressure may be so pronounced as to entirely obliterate all evidences of the existence of the nervous system so far as function is concerned.

The injury to the brain substance through traumatism to the head may be very slight, resulting in nothing more serious than a number of pinhead clots which times readily absorbs, or it may be so severe as to require active surgical interference to control the dangerous hemorrhage which is often present. In the more severe forms of injury the patient's loss of consciousness seriously interferes with completeness of diagnosis, but usually sufficient information may be obtained from the history of the accident and an examination of the patient's physical condition to enable the surgeon to arrive at reasonably accurate conclusions.

Where fracture of the skull exists, especially if depression be present, the most important factor to be considered is the condition of the skull contents. The fracture itself is of secondary consideration. Any violence of sufficient force to cause fracture of the skull has in all probability caused some injury to the brain tissue or its coverings, and this injury very evidently assumes a more serious aspect if the fracture be a depressed one, for in this event a section of bone will be pressed down upon the brain coverings and even fragments of bone may be forced into the brain substance itself.

In the consideration of any line of treatment in severe cases our thoughts should center on the probability of injury to the soft parts within the skull, and our efforts must be directed along the lines best calculated to overcome the *immediate* and prevent, if possible, the usual *remote* effects of the injury. Horsley has clearly established that brain scars, scars in the dura and depressed fragments of bone, are frequent causes of epilepsy, and that the removal of these causes usually results in benefit to and often in cure of the patient. We are therefore admonished to exercise great care, at the time of injury, in our efforts to prevent this result.

In outlining a general plan of treatment we would say that no one can hope to do satisfactory work on the skull. its coverings, or contents, unless he is surgically clean. We must not forget that infection is readily carried from the scalp to the brain or its coverings and that such an occurrence can not be too profoundly regretted and, when resulting through the carelessness or the unsurgical habits of the medical attendant, can not be too emphatically condemned. The clinical reports of all careful workers in this particular field of surgery go to prove that we may enter the cavity of the skull and there deal with conditions demanding surgical attention with the same confidence and assurance with which we enter the abdominal cavity, providing we exercise the same care and possess the same cleanliness. In all operations on the skull the entire head should be shaved and thoroughly disinfected before the skull wall is opened. All foreign matter should be thoroughly removed and, where dirt, hair, etc., have become lodged in the line of fracture, where fracture exists, the chisel and hammer must be used to remove them.

The next care of the surgeon is to ascertain, if possible, the nature and extent of the injury. Where fracture with depression is found, removal of a section of bone, either with the trephine or chisel, places the field of injury open to observation and clears up questions that must otherwise remain in doubt. In all cases sufficient bone should be removed to permit of a thorough inspection of the field of operation.

We now, with the injured parts easily within reach, proceed to treat them as we treat injured structures in other parts of the body. All foreign matter and bloodclots are to be removed, hemorrhage controlled either by hot applications, pressure or ligature, and all ragged edges of the wound excised, securing, if possible, smooth coaptating surfaces. The wound in the brain should be closed with catgut sutures, after which the dura mater is carefully drawn over it and closed with the same material and the outer wound closed and dressed in the usual way. When we feel that our work has been clean throughout, drainage is unnecessary, but if we fear subsequent septic trouble drainage should be provided for; the patient should be put at physical and mental rest and his condition carefully watched for at least ten days. Should septic trouble occur the parts must be opened up and a rigid antiseptic treatment instituted. He must ever bear in mind that the scar tissue resulting in wounds that do not heal by first intention is prone to be followed by those dreaded *remote* effects which are often immeasurably worse than death, and we should, therefore, leave nothing undone which may in any way conduce to or further the prospects of an aseptic result. In cases presented to us for treatment we must not carelessly overestimate or underestimate nature's possibilities, but rather by a careful consideration of all the conditions, facts and symptoms present, intelligently weigh the evidence and draw conclusions in accordance with its drift. Time spent by the surgeon in securing facts to strengthen his judgment is usually time gained for the patient and is therefore well spent.

This paper has not been written with the view of instructing, but rather of inviting attention to a field of surgery worthy, we believe, of more consideration than is being given to it and to stimulate a closer and more thorough study of the conditions with which it deals. Placed in positions where we may be called on at any time to assume the responsibilities involved in such cases we should, in doing even ordinary justice to our patients, be prepared to treat them with a fair degree of intelligence, and they should receive at our hands that degree of surgical skill to which in this day they are fairly entitled. The records of Macewen, Starr, Horsley, Fluchrer, Weismann, and others, combined with our present knowledge of surgical cleanliness, place us in positions to do at least reasonably accurate and successful work on the skull and brain, and when we consider the importance of maintaining the security and integrity of nature's great nerve center and its peculiar liability to injury, time spent in specially fitting ourselves for work in this connection can not be regarded in any other light than that of wise expenditure.

402 Grand Avenue.

TREATMENT OF TYPHOID FEVER.

WITH BACTERICIDAL IN CONNECTION WITH OTHER AGENTS, AND SOME CONSEQUENT DEDUCTIONS.*

J. M. PECK, A.M., M.D.
ARLINGTON, KY.

It would be remarkable indeed for any physician, be he the most humble or the most distinguished—or his work restricted—if he is not called upon to cross swords with the disease designated as *typhoid fever.* The treatment of a typhoid fever patient, as we shall attempt to describe, is the outgrowth of our acceptance of the now old and universally admitted theory as enunciated by Eberth, and, except in rare instances, the primary and principal site of infection is in the intestinal tract, although there may be undoubted cases in which there is no perceptible inflammatory process in the alimentary canal.

Taking the fact for granted, then, in the great majority of cases that entrance of the bacilli into the system is by means of the ingesta, we would naturally expect the first local manifestation to be somewhere in this tract. This we find to be the actual condition in nearly all cases. In many cases, one of the earliest and most noticeable symptoms is a peculiar diarrhea, which we take to be a well-directed effort of nature to rid herself of the disturbing elements there. Bacteriologists and pathologists of to-day assert that the real disturbing element is not so much the bacilli themselves, but the toxins produced by them. The toxins are the cause of the toxemia, and when this toxicity is extreme, we have a condition of mental and physical inactivity so familiar to us all who have treated or witnessed many typhoid patients treated according to the old expectant way of management. If the Brand or any other treatment has no recommendation above the old, beyond the preservation of the mental faculties, for this alone they would demand our adoption in every possible instance. It seems the Brand method would favorably impress every thinking mind as meeting in a great measure almost every indication possible to be met in an uncomplicated case of typhoid fever except that to be met by means of intestinal antisepsis. But happy is the physician whose clientele is of sufficient wealth that he may carry the Brand treatment into their homes without frequently meeting insurmountable obstacles; or, on whom his grip is so strong that he will not run serious risk of losing desirable patronage and influence. In hospital practice the cold plunge bath stands easily first as a favorite treatment by the leading teachers of the day, but a large majority of the typhoid patients are treated outside of the hospital, and the question arises, what is the most expedient and successful way to treat them? Our very limited experience is to the effect that the nearest approach, in many respects, to the Brand treatment will be attended with the greatest success.

Elimination of the bacilli and also their toxins, in every way possible, not detrimental to the patient, is the very important object to be attained. This is effected chiefly through the bowels and kidneys, and possibly to a certain extent through the skin. Nature usually begins this eliminative process by a diarrhea, as above stated. In accord with this idea, we should assist by as thorough a cleansing of the bowel as possible. The drugs on which we most rely for aid in this therapeutic endeavor are calomel and chlorin. As a germicide and purgative, calomel meets two important indications. It may be given in from 1/10 to 1/2 grain doses every half hour, as conditions may demand, until six or eight doses are taken. As soon as the bowels move because of the calomel, there should be a free washing out of the bowel with sterilized water, the effect of which may be improved by the addition of a dram of salt to a pint of water. This flushing will do much toward assisting nature, as well as contributing to the comfort of the patient. The course of the calomel, in varying doses according to the susceptibility of the patient to the drug, should be repeated every twenty-four to forty-eight hours. The wash should be repeated as often as the emergency demands, in proportion to the meteorism or bowel trouble. The antiseptic or germ-destroying property of chlorin has long been recognized as very powerful, while at the same time experience has amply proved that it is harmless to the animal economy. Then in addition to this cleansing effect of the calomel, and the washing, on the bowel and contents, we may give chlorin in aqueous solution and still nearer approach a condition of asepsis in the bowel and thus render it less inviting to the bacilli. My favorite way of preparing chlorin is that recommended by Dr. Yeo, with the exception of quinin, which I omit. Take potassium chlorate, grains 30, acid hydrochloric, minims 60, and distilled water 12 ounces. Put the potash in a dry bottle of sufficient size, add the acid, cork the bottle and allow it to stand until chemical action ceases, then add 3 or 4 ounces of the water at a time and agitate thoroughly. This is repeated until the preparation is complete. A tablespoonful is given to an adult every two hours until the offensive character, if such exists, of the evacuations is removed, then the interval is lengthened at night but continued in the day until convalescence is established. By this constantly lax condition of the bowels, the repeated washing out from below and the frequent imbibing of the chlorin solution serves to sufficiently free the bowel of the disturbing elements so that meteorism and its accompanying evils are in a great measure prevented. Autointoxication from this source is reduced to the minimum. So much then in the way of lessening, as well as the removal of a portion, of the products of infection which occur in the intestines. Professor Osler, at the meeting of The Association at Baltimore, some five years ago, stated that "the only thing developed by this intestinal antisepsis is that the walls of the bowel could stand considerably more irritation and strain during typhoid fever than had been supposed." As revealed by the light of to-day that statement should be corrected as follows: Intestinal antisepsis, during typhoid fever, tends to protect and strengthen the walls of the bowel and to that extent is a preventive of extensive sloughing, hemorrhage or perforation.

---

* Presented to the Section on Practice of Medicine, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

In this connection, we next come to the consideration of hydrotherapy as an additional means of sustaining the vital forces, and promoting elimination of the toxic products through the kidneys and skin. In private practice the ideal hydrotherapy is by the sponge bath, hot and cold. Its practicability at once commends it to your intelligence. Any patient who with the aid of his family or friends is unable to carry out this modification of the Brand treatment should be sent to the hospital, where water and nurses are abundant. The familiar maxim, "the greater the skill the better the service," is true in this as well as other callings; for the sponge bath very little skill and usually one nurse will suffice. The free use of sterilized water internally should be maintained throughout the attack, and externally, as conditions may require. If the patient can not take it into his stomach, inject 16 to 20 ounces into the bowel at stated intervals and the effect will be almost the same. We might say he should be drenched internally and externally with water. Internally it acts as a solvent and carrier of the waste matter, to a degree, like flushing out the sewers of a city. It facilitates intestinal antisepsis, it feeds and soothes the famished and parched tissues, favors metabolism, and induces sleep, nature's great restorer. If we follow up this effect with the free use of water externally, hot and then cold, the first effect is the shock, the severity of which depends on the temperature of the water and the hyperesthetic condition of the patient. As a result of the reflex action produced on the nervous system, we have expansion of the lungs, increased elimination of carbon-dioxid, increased oxygenation of the blood, increased blood-pressure, and a consequent increased activity of the lymphatics and other glands, especially the kidneys, which means an increase in the excretion of the toxins in the fluids of the body, and for your patient a bright eye and a clear head. The cold pack or sponge bath does not cause so pronounced a reaction as does the cold plunge bath; neither is it so terrifying and hazardous to the patient. At periods during an attack of typhoid fever the temperature in the majority of cases runs high, so much so that the patient is distressed. The nervous tension is too great, causing extreme restlessness, and if the sponge bath does not relieve it we must resort either to the cold plunge bath or give an antipyretic. What shall we do? In many instances it would be impossible to use the cold bath, in others still, it would be more dangerous than the drug. In the hospital you might use the plunge bath, but in private practice I would give acetanilid, and in about thirty minutes the patient is quiet, the skin is bathed in perspiration and the temperature is coming down within reasonable bounds. Often we will have among our patients those who have rigors. One will complain of being cold, or the extremities are cold while his body is hot, and we find the circulation very rapid and a temperature ranging from 104 to 105.5. If you give him 3 or 4 grains of acetanilid and re-apply ice-cold applications to his head, usually in fifteen or twenty minutes he will begin to complain of burning up. Having experienced this ordeal I can state from personal knowledge that the sensation is one of extreme heat over the surface. But to the patient. In five or ten minutes longer you find him perspiring, the extremities warm, and he expresses himself as feeling comfortable. The exact way in which this effect is produced, I am not yet able to demonstrate, but from repeated observation I am sure that through the nervous system the acetanilid causes dilatation of the peripheral blood-vessels and thus allows the hot blood to flow from the congested parts to the surface, the cooling area. The radial pulsation is slower and shows greater volume. This allows rest for the overworked heart.

Much prejudice exists against the coal-tar derivatives as antipyretics. This prejudice exists in the minds of many of our most learned, but in not a few instances it is held by those who have had very little if any personal experience with them as antipyretics. That they are remedies which should be used with great caution, there can be no question, but that they should be discarded because some have dared to use them recklessly and met with disaster, is not warranted. On the same plea we will strike most every remedy of value from our list.

Along the latter part of the year 1895, I began the treatment of typhoid patients with the view of destroying and removing the bacilli and their toxins in the manner described, believing it to be the rational way of assisting in the correction of the pathological conditions. Since that time seventy-seven typhoid patients have come under our care with the result that all of them recovered. I might say, were permitted to recover, because some advocate the idea that patients so treated, when they do recover do so in spite of the treatment. The youngest of these patients was 4 years of age, and the oldest 63 years. They represent the various callings and conditions in life, from abject poverty to that of plenty. Their nursing and feeding as a rule harmonized with the intelligence and ability of the nurse to carry out the instructions. Diet was restricted to liquids and semi-liquids. Fruit juices were served in liberal amounts if the patients desired them and they could be obtained. If they so desired, they were permitted to masticate and suck the juices of broiled steak. The duration varied from nineteen to sixty-five days, though the average time was only twenty-five and one-tenth days from date of onset to a continued normal temperature. Except when temperature was high they all remained rational. No preparation containing opium was used at any time, save in one case of severe hemorrhage. Hemorrhage occurred in six cases, though very slight in five of those. Ice over the bowels and an enema of cold water containing extract of witch hazel were all that was used to control the hemorrhage in these. In the other case the hemorrhage was so severe and repeated, tincture of opium was added to the injection of witch hazel and water. Aside from this case, no effort was made at any time to check the bowels except by cleansing. When there is diarrhea, a part of the expectant plan is to control that diarrhea by sedatives and astringents, the idea being to preserve the vitality of the patient.

By a comparison of my results with those obtained by others, while employing the expectant plan coupled with the sponge bath, it is found that the results secured by the bath and intestinal antisepsis are the more favorable. The conclusion is that it is a mistake to check a diarrhea in typhoid fever except by the use of a purgative or by a thorough washing with sterilized water. By this, many of the bacilli and their toxins are carried away by the dejecta. Results indicate that the chlorin solution has a very beneficial effect in checking the production of the toxins, or by rendering them less active. That the toxins are largely produced in the glands, lymphatic and others, is not proof positive that the chlorin does not come in contact with them there, to some extent. It is evident that it does, in some way, to a certain degree, destroy or render inert, either in the bowel or elsewhere, a sufficient amount of them to prevent their producing that profound toxicity formerly so common in the disease. It is not held, in the seventy-seven cases reported, that the chlorin was the sole agent in the prevention of the toxemia. The effect of the calomel with the flushing of the bowel, prepared the way or acted as a stepping-stone for the chlorin. The cold bath, through its effect on the nervous and cardiovascular systems, greatly increased the elimination of toxins through the kidneys. With the united effect of these remedial measures the patient is enabled to recover in a shorter period, and with a saving of vital force. In well-regulated hospitals where the patient is under the care of skilled nurses, and no imprudence in the diet could occur, and every detail as to treatment is faithfully adhered to, relapses would be rare and the course of the disease correspondingly shortened. We have the above statement, notwithstanding the reverse opinion is held by gentlemen of recognized and distinguished ability.

DISCUSSION.

Dr. C. Birnie, Taneytown, Md.—My opinion is that the majority of cases result from the ingestion of contaminated water and not through breathing air. The patient and his surroundings should be kept clean and the excretions disinfected, so that neither air nor water be contaminated. I believe that typhoid fever is more easily treated where the bowels are loose. In talking with a prominent man, he told me that he prayed for constipation. I have never found that constipation was a thing to be desired in the treatment of this disease. I think that cool bathing is of great importance, but in country districts it is impossible to carry out the Brand method in all its details, and I can not agree with any statements made that we should treat typhoid fever antiseptically; I believe that this is impossible. Typhoid fever is a disease of the whole body and not of the intestinal tract alone. I disagree with the statements made regarding antiseptics; when we consider the canal, from the mouth to the anus, a twisting and turning canal, there is no known means by which we can antisepticize it. I think flushing the colon is useful, and I have known it to give relief to the flatus; for that it is good. There is a large number of cases that will get well under any reasonable line of treatment. Prescribe for the patient and not for the disease.

Dr. A. E. Roussel, Philadelphia—It has been within the last six weeks that I made a post-mortem on a patient of mine at the Howard Hospital, a young woman about 26 years of age, who had hardly any congestion of the intestinal tract: the most minute observations revealed no break of continuity of the tissues, yet the case responded to Widal's reaction and was evidently one of typhoid fever. How frequently do we see cases with marked meningeal symptoms due to the same cause! Therefore I consider the statements regarding the value of intestinal antiseptics as largely exaggerated. There has been a marked reduction in the mortality from the use of the Brand method. Where the entire treatment can not be carried out I believe that portable bath-tubs should be used. In those cases where a trained nurse can not be procured the application of the baths does not require a great range of intelligence; the member of the family acting as nurse should be taught how to take the temperature, and when the tubbing should be applied. I think the difficulties of applying the Brand treatment has been widely exaggerated. We know positively that before this method of treating these cases was in vogue the mortality ranged from 18 to 20 per cent., while now it runs from 5 to 10 or 11 per cent. I can not fully agree with the last speaker's remarks that those cases which show a mild degree of constipation are more severe and show a larger mortality. Dr. Wilson has had applied in the wards of the German Hospital the Woodbridge treatment, and among the 18 or 20 cases the results were far from being satisfactory. I think there were four or five deaths out of the above number of cases. I have tried many drugs and I have tried cold water, and the latter has proved by far the most efficacious. As regards the entrance of the germs into the system, I think it is undoubtedly in the vast majority of cases through the water-supply, so far as it has been demonstrated. But it is fair to assume that the germs may enter the system through one or more than one channel.

Dr. Louis Faugeres Bishop, New York City—I also wish to state that the antiseptic treatment of typhoid fever has brought nothing but disappointment. I have tried chlorin and other mixtures, and have been disappointed in all. Typhoid fever is a general disease of the whole system and the intestinal tract is not the road through which we should treat it. The opinion of the whole medical world will support the Brand treatment. We should on every occasion preach and teach it. There is one practical point that is worthy of mention, i. e., that a tub is not necessary. In New York City in private practice we seldom use tubs any more. The nurses have learned how to arrange their patients in a rubber sheet, which answers just as well as a tub. Of course these baths are given by skilled and trained nurses. The tub is safer in unskilled hands. As to the merits of the Brand method, all are agreed that its chief merit lies in the support it gives to the circulation and the restoration of the nervous system, and that any reduction of temperature is a secondary matter, though, of course, important. When the patient gets a cold bath the effect is the same as it is in health; the respirations are deepened, the circulation is increased, the nervous system is wonderfully uplifted. It does not diminish the number of intestinal hemorrhages or perforations, but it certainly does not increase them.

Dr. H. M. Fussell, Philadelphia—I am glad that I heard it mentioned that a modification of the Brand method can be used in private practice. After protecting the bed and floor with the rubber sheet, the water should be allowed to fall upon the patient from a height of from four to five inches above his body. I may have mistaken Dr. Peck's point in reference to antipyretics and I can not let his remarks go unchecked, because it is so much easier to give drugs than to give the baths. Antipyretics certainly reduce temperatures, but not in the same way as the cold bath does. I do not believe that intestinal antiseptics, given in a general way, do any good, but I have used in conjunction with the Brand treatment salol as a local measure. If there is a severe case of diarrhea, this is checked by this drug. I think we should depend upon cold water

Dr. J. M. Peck, in closing—Evidently some of the gentlemen failed to hear or else misunderstood the ideas expressed in the paper. I did not intimate that typhoid fever is a local disease, but that in typhoid fever we may, and usually do, have in the intestinal tract a local manifestation of the disease. The view taken in the paper is in perfect accord with that of the bacteriologist and pathologist of to-day. The degree of toxemia depends on the amount of toxins, and their amount depends on the multiplicity of the typhoid bacilli; hence our contention that any means by which only a part of the bacilli are carried away or the intestinal tract rendered less inviting to, or less favorable to the production of, the bacilli is so much to the help of the patient. Our experience with cases in which a constantly lax condition of the bowels and free flushing of them with sterilized water and frequent ingestions of chlorin fully justifies our faith in the treatment. This kind of intestinal antisepsis combined with the external application of cold as suggested in the paper will yield better results in private practice than any other yet suggested. If those using the Brand method exclusively will add to it intestinal antisepsis they will improve on their already good results. I do not believe the intestinal tract can be made strictly aseptic, but am thoroughly convinced by clinical experience that the septic products may be so reduced that auto-infection and auto-intoxication are kept in comparatively safe limits. The objection raised that the chlorin is a nauseous dose is purely imaginary, since by the addition of aromatics the most fastidious may be pleased. To be sure, the coal-tar derivatives should be used with caution, and when so used the life of your patient is in no sense endangered thereby, but is actually safe-guarded. The fact that they are potent drugs should not cause us to discard them any more than should strychnia, belladonna and a host of other powerful, but exceedingly valuable remedies be discarded. I repeat that, with judicious use, there is no danger of, or excuse for, killing a patient with acetanilid.

Violation of Quarantine.—An eclectic practitioner of Appleton, Wis., who has achieved a somewhat unsavory notoriety by his recent flagrant violation of accepted health regulations, who escaped from quarantine at Appleton, and passed through Chicago to Terre Haute, Ind., was apprehended in Milwaukee, January 30, and sent to the isolation hospital there.

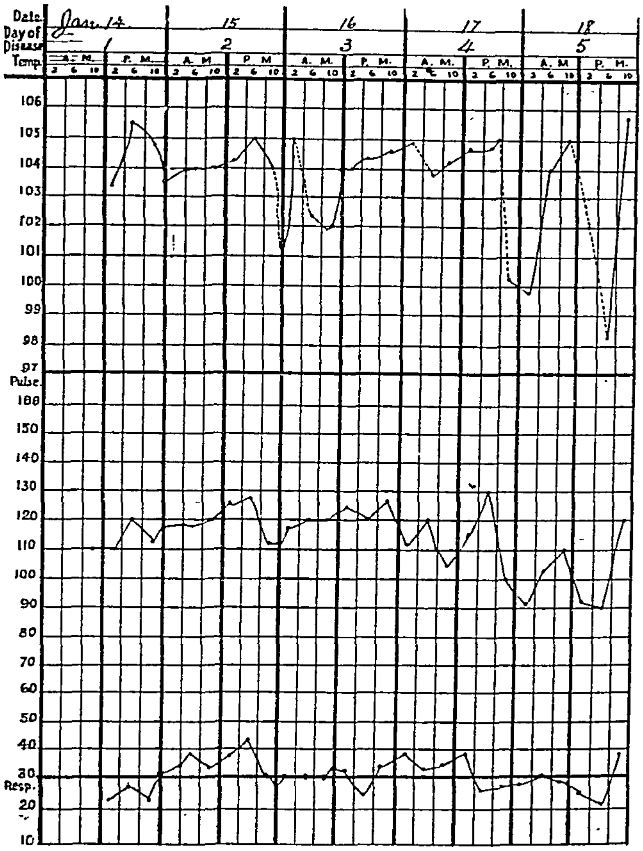
INFLUENZA, ACCOMPANIED BY FOUR DISTINCT PNEUMONIC ATTACKS.

OTITIS MEDIA PURULENTA AND CEREBRAL HYPEREMIA, COLITIS, INANITION—RECOVERY.

JULIUS ULLMAN, M.D.
Instructor in Clinical Medicine, University of Buffalo; Late Acting Assistant-Surgeon, U. S. A.
BUFFALO, N. Y.

As excuse for recital of this case may be given its very unusual course and happy termination in recovery.

Allen D., aged 23 months, suffered during last summer from a dysenteric diarrhea, for which he spent two months on a farm and ultimately recovered. Twelve days previous to the present illness, I treated this baby for parotitis. On January 12, when I called I found him irritable, with flushed countenance and considerable amount of dry cough; temperature 103.6; pulse 112; respiration 32. The tongue was coated, and there was anorexia. The examination of the chest revealed by auscultation, subcrepitant râles, especially over both bases of the lung posteriorly. The onset was abrupt and the baby soon showed a marked apathy due to toxemia.



First Attack.

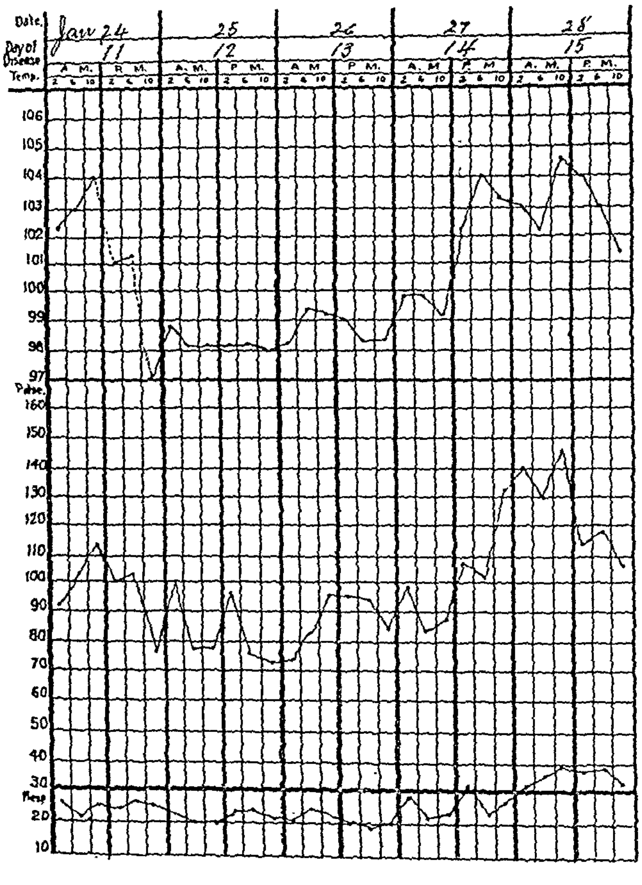
In the further discussion of the case I shall confine myself to the interesting and unusual temperature chart herewith presented.

The first attack of pneumonia, which was of a bronchopneumonic type scattered with here and there very small areas of consolidation, was associated with a very high temperature-curve, reaching a maximum of 105.6 F. The respirations were as high as 42, and the pulse at one time reached 135. The lines, indicating the abrupt fall of the temperature, show the effect of cold sponges and packs.

---

* Presented to the Section on Practice of Medicine, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

The first temperature-curve dates from January 14 to 24, eleven days inclusive. On the 9th and the 10th there was a blueness of the lips; the respirations were shallow, the pulse feeble and frequent, and emesis appearing it became necessary to give nourishment and medication by enemata. The babe meanwhile, first apathetic, became comatose; the eyes strabismic, the legs and arms strongly flexed and rigid, the head retracted, and with Kernig's sign, it was thought a complicating meningitis developed, but fortunately this was in all probability due to the active cerebral hyperemia resulting from the hyperexia, for on January 24, the eleventh day, the temperature suddenly descended by crisis and the pulse and respirations were reduced to normal. It was thought that the babe had withstood a severe type of influenza pneumonia, but we were disappointed, for after two days of calm—twelfth and thirteenth—the temperature, pulse and respirations again abruptly rose; there was again developed a dry cough, and on examination of the chest there was found complete consolidation of the left upper lobe with crepitant râles and a distinct quality of bronchial breathing. The child meanwhile showed great prostration, with respirations frequently dyspneic and shallow, reaching 40. There was great restlessness and irritability and the baby acted as though in great pain. Because of the manner in which he would raise his hand to the face, our attention was directed to the examination of the ears, and a slight purulent discharge—otitis media purulenta—was noted from the right ear; this affection, after the usual treatment, improved in a few days so that the patient was less fretful and suffered less pain.

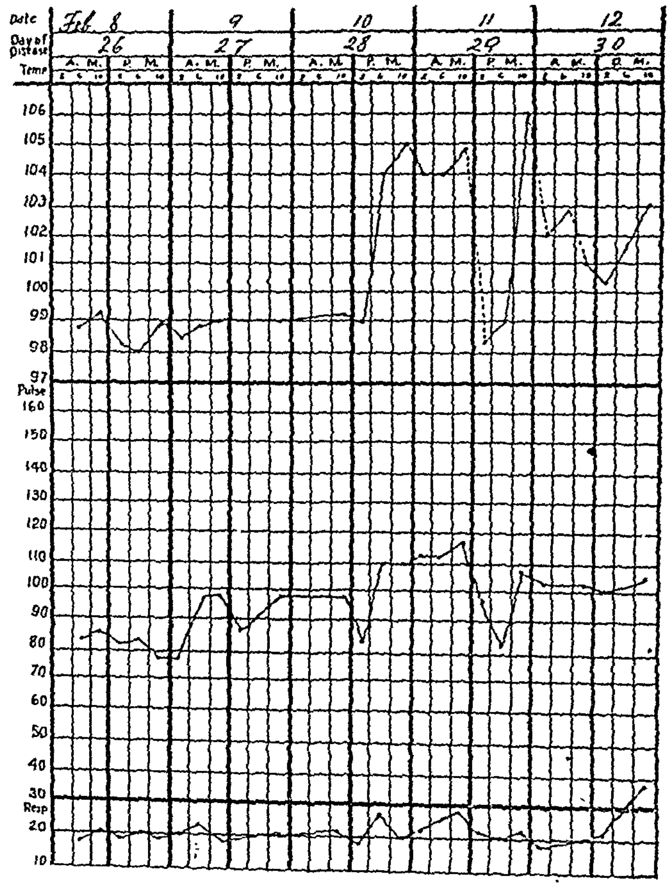


Second Attack.

The tongue was coated, well-marked tympanitis was present, and it was noticed that the dejecta contained quantities of mucus, so that it became necessary to institute high-bowel washes. This attack lasted from January 27 to 30—fourteenth and seventeenth days of disease—inclusive, when temperature, pulse and respirations again descended by crisis, reaching a subnormal point, 97. The pulse became stronger and less frequent, the respirations fuller and easier, and the patient perspired freely.

The babe, because of his inability to properly take and assimilate nourishment, was anemic and lost in strength and flesh, so that beginning with the second period of calm, inunctions of cod-liver oil were given daily. This second period of calm, during which the consolidation of the right lower lobe with crepitant râles appeared, was ten days in duration—January 31 until February 9, eighteenth and twenty-eighth days of disease.

On the afternoon of February 10, or twenty-eighth day, there occurred another abrupt rise of the temperature, and on examination of the chest, a new area of consolidation of the right lower lobe with crepitant râles and bronchial breathing was found; the left lower lobe gave by auscultation evidences of subcrepitant râles, but no consolidation.



Third Attack.

This attack, extending from the twenty-eighth to the thirty-fifth days, was especially severe, the chart reaching on the 13th at 10 p.m., temperature 106; pulse 128; respiration 42. The cheeks were flushed, suggestive of the hectic flush of phthisis. On the 16th there appeared a herpes labialis; there was cyanosis; the respirations were labored, shallow and cautious; the pulse was frequent, small and intermittent. There was anorexia and great irritability, the patient often refusing to swallow nourishment or medicine. Tympanites and tenesmus developed, and the dejecta showed large quantities of mucus. Again the arms and legs were often retained flexed and rigid and the head retracted. A great loss in weight and strength was noted during the attack.

On February 17 a crisis again occurred. The temperature remained normal for seven days inclusive.

On March 24, the forty-second day, there was another rise of the temperature, pulse and respirations; however, no such elevation was reached as in the previous attacks, for the reason that there was less reaction to the toxemia. The cough was dry and regularly paroxysmal. The lungs showed no consolidation, but subcrepitant râles and a bronchovesicular quality of breathing were detected over both bases, the left interscapular and mammary regions.

The colitis still continued and there was an anemia and emesis with great emaciation, the muscles becoming very much atrophied. The babe presented the appearance of inanition, and because of the continuity of fever, the hectic flush, the colitis, perspirations, the morning remissions of temperature, we were led to differentiate between influenza, malaria, remittent fever, tuberculosis and sepsis, i. e.. empyema.

It was at this time a blood examination was undertaken by Dr. A. E. Woehnert, the report of which follows:

> The hemoglobin was 50 per cent.; the erythrocytes numbered 3,500,000. There was a leucocytosis, but not of the polynuclear type, of 14,000. Lymphocytes, 97 per cent.; polynuclear leucocytes 3 per cent.; no eosinophiles, microcytes, poikilocytes. A picture of chloranemia or severe form of secondary anemia.

In the presence of leucocytosis we were justified in excluding a tuberculosis without cavity formation. A tuberculosis with secondary cavity formation could be excluded by, 1, the lack of physical signs; and 2, by absence of a polynuclear leucocytosis.

Empyema was excluded by physical signs, but in view of the fact that our patient appeared pyemic and that the temperature-curve reminds one of pus, and also because there are some cases, especially in infants and very young children, which give no absolute physical signs and which can only be positively diagnosed by exploratory puncture, the absence of polynuclear leucocytosis excluded it.

The blood examination, therefore, was of assistance in diagnosis in excluding the diseases enumerated above. The secondary anemia can be attributed to the toxic effects of the existing infection on the erythrocytes, causing a loss in the hemoglobin and their partial destruction. As to the increase in the lymphocytes, it was not sufficient to be attributable to a leukemia, and of this there were no nodular or splenic signs, otherwise than could be attributed to the existing inanition. Cabot regards an increase of a leucocytic count in infancy as made principally of lymphocytes, and this change is to be regarded as a mark of the arrest of the development or reversion to an earlier type of tissue. Unfortunately, we did not seek the influenza bacillus, but the prevalence of the disease sporadically at that time and the behavior and course of the history, especially considering the susceptibility of the patient after the attack of parotitis and the exclusion of the other diseases previously considered, left no doubt in my mind as to the diagnosis. The last edition of Ashby and Wright says the diagnosis often has to be made by process of exclusion and nature of epidemic prevailing.

It is interesting to note that we had: 1, an influenza bronchopneumonia scattered and in very small patches giving no definite areas of consolidation, but which showed the characteristic physical signs by auscultation; 2, that the second and third attacks were either, *a*, lobar consolidation in which the organism affected primarily the alveoli, such as is described in Frinkler's monograph on influenza, or, *b*, that the lobules quickly coalesced giving a lobar variety of bronchopneumonia, or, *c*, that there was added a complicating true diplococcus or streptococcus pneumoniæ producing characteristic consolidation.

Purulent otitis is a very frequent complication of influenza. It may appear during the course of the disease or convalescence. It may be produced by the influenza bacillus, but often is a secondary infection due to pyogenic bacteria. Every epidemic of influenza increases the quota of diseases of the ear, and this complication should be carefully sought for.

Lastly, the colitis may be regarded as belonging to the intestinal manifestations of the disease and probably produced by swallowing the sputum, and the condition of inanition becoming secondary to the intestinal lesions and long continuance of the infection which must have produced changes of an atrophic form in the secretory function of the intestinal tract.

In view of the bad prognosis in children of influenza complicated by pulmonary disease, the severity and multiplicity of the pneumonic attacks and the ultimate recovery are emphasized.

It is a year since I first saw the child and the recovery is absolute. The child has gained in strength and weight and the lungs and other organs are normal.

AURAL MANIFESTATIONS OF SYPHILIS.*

FRANCIS R. PACKARD, M.D.
Otologist to the Out-Patient Department of the Pennsylvania Hospital; Instructor in Laryngology, University of Pennsylvania; Dean of the Philadelphia Polyclinic, etc.
PHILADELPHIA.

Among 2500 consecutive cases treated in the outpatient department for diseases of the ear of the Pennsylvania Hospital there have been but seven in which the trouble was distinctly of syphilitic origin. They were as follows:

Case 1.—A man, white, aged 25, a musician, presented himself suffering from undoubted secondary syphilis. There was a very general squamous eruption, and he had lost a large amount of hair. He had a chancre seven months before. There were several large squamous syphilids on his right auricle. These healed completely after a course of mixed treatment, accompanied by the local application of calomel ointment.

Case 2.—A woman, white, aged 27, with marked symptoms of tertiary syphilis, had been deaf in the left ear for four years, and had suddenly lost her hearing in the right ear four days before coming to the dispensary. She suffered also since the trouble in her right ear had begun from very severe vertigo. There was total loss of bone conduction. The diagnosis of syphilitic labyrinthine deafness was made, and under large doses of potassium iodid she speedily improved. She passed from under observation before her hearing was completely restored, but her rapid and steady improvement gave us reason to hope that she would have regained it if she had persisted in the treatment prescribed for her.

Case 3.—A boy, white, aged 9 months. The mother said the child's father had syphilis. When brought to the dispensary it had a large gummatous mass, which had broken down and formed an abscess, involving the auricle and the tissues above and in front of it. There was much glandular enlargement in other parts of its body and it was very weak and miserable looking. The mother said it had had "the snuffles" since birth. The pus was evacuated, and under specific treatment the child improved rapidly.

---

* Read in part before the Section on Otology and Laryngology, College of Physicians, Philadelphia, March 21, 1900.

CASE 4.—Boy, colored, aged 9 years. For one week previous to coming to dispensary he had complained of roaring in the ears and deafness. There was no pain and no discharge from the ears. The drums were intact, very slightly retracted. Aerial conduction was slight and bone conduction was lost. The boy was poorly nourished, had Hutchinson teeth, and enlargement of post-cervical lymphatic glands. Under specific treatment he began to improve, but soon ceased coming to the dispensary.

CASE 5.—A colored man, aged 25, bartender, suffered from secondary syphilis. Four weeks previous to coming to the hospital his right ear began to swell; the swelling was intensely painful. The man positively asserted that he had sustained no injury and there was no evidence of any previous injury or furuncle about the ear. He recovered completely on potassium iodid internally, with the local application of yellow oxid of mercury ointment to the ear. This case I have already reported.*

CASE 6.—A woman, white, aged 30, single, domestic. Twelve years ago she had an abscess in the frontal region, accompanied by much loss of frontal bone substance, leaving extensive depression and scarring over forehead. There was a large perforation through the bony portion of the nasal septum. Her hair was scanty and quite gray. Four years ago she had gone to bed one night with apparently perfect hearing, but when she awoke was hardly able to hear anything with the right ear, and in a few days became deaf in both. She is now under treatment for specific iritis. Examination showed membrane opaque and retracted. Both bone and aerial conduction of sound were totally lost.

CASE 7.—A woman, white, aged 55 years, mother of Case No. 6. She came with her daughter to the outpatient department and said she was "going deaf." Examination showed both drums very fibrous and opaque. In the right ear she was deaf to both aerial and bone conduction. No definite history could be obtained as to whether her deafness had been of sudden onset or otherwise. There was a large perforation through her bony septum. She denied with great vigor the possibility of syphilitic infections either of herself or her daughter, declaring that her husband had been a perfectly healthy man until his death from some acute disorder some years ago. She had no other evidences of syphilis than those narrated above.

I do not think that syphilis can be a very frequent source of ear disease, as if it were, there would surely be more frequent mention made of it, and yet when we realize how many of the patients who come to dispensaries are the victims of syphilis, in many cases not manifest on superficial examination, it is possible that sometimes syphilis as the underlying cause of their trouble may escape our notice. In the cases I report, the diagnosis was plain, but in going over the literature on the subject one is struck with the great variety of ear lesions which have been described as occasionally of syphilitic origin. It seems to me very probable that many seemingly most obstinate cases which do not yield to local treatment may possibly be due to syphilis and only awaiting proper constitutional treatment.

Knapp[1] quotes the following startling statement by Hinton: "Hereditary syphilis furnishes more than one-twentieth of all the aural patients at Guy's Hospital." Knapp says that this is certainly not a correct estimate as regards the frequency of such cases in other places.

EXTERNAL EAR.

Primary syphilis of the external ear is extremely rare. Politzer[2] refers to four cases. One was reported by C. Pellizzari[3] in which infection followed the use of a handkerchief that had been previously used by the syphilitic son of the patient. The second was reported by J. Zucker[4] as resulting "from the too fervent love-caress of a publican." The third case was reported by Hermet[5] as occurring in a woman who was caressed by her syphilitic husband. The fourth case was related to Politzer by Hermet, and was a phagedenic chancre on the auricle and lobule following the bite of a syphilitic. Depres[6] reports a case of chancre of the auricle. L. Duncan Bulkley[7] in an analysis of 9058 extragenital chancres found 27 cases in which the chancre was located on the external ear. He reports one case occurring in a man whose ear was bitten by a man who had mucous patches in his mouth. Mracek[8] in a study of 400 cases of extragenital chancres found but 3 located on the external ear.

Secondary and tertiary manifestations of syphilis of the most varied character are described as occurring in the auricle and external auditory canal. Any of the ordinary cutaneous lesions of syphilis may involve the auricle and canal. Thus, one case I report was that of a man in whom a syphilitic skin-eruption of squamous nature had extended to the auricle. Knapp[9] reports a case of condylomata occurring in both external auditory canals in a woman who had contracted syphilis six months previously. He refers to a very similar case mentioned by Wilde in his "Practical Observations on Aural Surgery," and to the fact mentioned by Stöhr[10] that he had seen 14 cases of broad condylomata of the canals, 11 of which were in females. Also Noquet[11] refers to bilateral condylomata of the external auditory meati. M. A. Goldstein[12] reports an interesting case of bilateral syphilitic ulceration of the auricle in a colored man who had contracted syphilis six months before. G. W. Linthicum[13] also saw bilateral syphilitic ulcers of the auricle in a negro. C. D. Roy[14] reports a case of condylomata of the left external auditory meatus in a colored man who had secondary syphilis. R. Barclay[15] reports an interesting case in which syphilitic ulceration of the auricle resulted in sequestration of the cartilage of the concha and membranous atresia of the canal causing deafness, which was relieved by operation. H. Mendel[16] reports the case of a woman who eight months after contracting syphilis developed an intense cellulitis of the auricle. Würdemann[17] describes bilateral condylomata of the external auditory canals in a man who had had a chancre fifteen years before. A. H. Buck[18] saw three cases of syphilitic ulceration of the external auditory canal. Depres[6] in 1200 syphilitics observed condylomata of the external auditory meatus in five cases. Politzer[19] refers to a case seen by Lang, in whom there was a syphilitic papule in the position of the short process of the malleus in a woman with general syphilis. Politzer saw a characteristic syphilitic ulcer form on the inferior wall of the meatus in the course of a chronic suppurative otitis media. The patient had likewise pharyngeal syphilis. In another case he saw a syphilitic ulcer occupying the whole length of the cartilaginous wall of the meatus, accompanied by another syphilitic ulcer on the concha. The *Philadelphia Medical Journal* of March 4, 1899, contained a paragraph stating that a case of gumma of the helix had been seen recently at the Ricord Hospital in Paris, and had excited much attention because of its rarity.

---

* In Philadelphia Medical Journal, June 24, 1898.

Hereditary syphilis of the ear manifests itself most frequently in the middle and inner ear. One of the cases I report in which the external ear was involved, however, was hereditary, namely, the gumma of the auricle in the child.

MIDDLE EAR.

Syphilitic disease of the middle ear most usually originates from infection through the medium of the Eustachian tube. Politzer says that Itard[20] described purulent inflammation of the middle ear following syphilis. He cites Ricord, Lancereaux, Blanchet, Fournier, Bonquoy, Laboulbène and Baratoux, as having observed "primary chancroid ulcers at the ost. pharyng. tubæ. They may occur as the result of catheterization."

Jonathan Hutchinson[21], in describing a number of cases of syphilitic disease of the ear, remarks that facial paralysis as a result of syphilitic disease of the ear, though less common than deafness from that source, is sometimes seen, and several of the cases he reports presented such paralysis. One of his cases of secondary syphilis lost his hearing simultaneously with the development of facial paralysis. He recovered from the palsy, but remained permanently deaf. Another case developed facial palsy accompanied by intense earache, but without any impairment of hearing. Hutchinson attributed the condition to syphilitic inflammation of the structures in the middle ear which did not extend to the external ear. Elsewhere[22] Hutchinson says that otorrhea is not a prominent symptom in syphilitic ear disease, adding, "I have never yet seen a case of profuse otorrhea attended with ulceration, growths of granulations, etc.—such as are common in cachectic or strumous children—in an heredito-syphilitic otitis. Hutchinson thinks that secondary syphilitic otitis is to be regarded as analogous to secondary syphilitic iritis, and that the lesions it creates are usually permanent. The deafness of tertiary syphilis, he says, is of less importance, and is usually temporary.

Woakes[23], on the other hand, observes that many cases of "so-called strumous otorrhea in children are due to an inherited taint (of syphilis)." He thinks syphilitic caries of the bone is frequently responsible for the long-continued suppuration.

Hereditary syphilis was considered by A. C. Cotton[24] as the causative factor in the case of a child of 15 months who had other undoubted evidences of the disease associated with chronic suppurative otitis media in both ears.

F. M. Wilson[25] publishes the aural history of an undoubtedly syphilitic family, in which, out of five living children, three had chronic suppurative otitis media. Dr. Wilson says that these cases may have been due to syphilitic disease of tympanum, or to lowered vitality, or else were merely coincidental.

Burnett[26] describes the interesting case of a man who went to bed with apparently normal hearing, but on arising found himself deaf in the right ear and suffering much from tinnitus in it. Examination revealed hearing normal in left ear, but hearing was lost to air conduction in the right ear, remaining normal, however, for bone conduction. There were evidences of syphilis in the throat. As there was no loss of bone conduction, although the deafness was of sudden onset, Burnett attributed the condition to the fact that granuloma, or circumscribed, small round-cell infiltration, had formed in the tympanum with great rapidity, and had by fixation prevented the normal movements of the conductive apparatus from being performed.

John Dunn[27] reports a case of exudation into the membrana tympani about the head of the malleus in a man who had manifestations of secondary syphilis. The membrane was punctured and under specific treatment the exudate disappeared. Dr. Dunn attributed the local condition to the constitutional disease.

INTERNAL EAR.

Of the cases which I report, four presented evidences of syphilitic disease of the internal ear. It is generally very late in the course of syphilis before lesions of the internal ear manifest themselves. Like almost every other subject in medicine, at one time much was said and written on the subject, but of late it has been allowed to drift into innocuous desuetude, not, however, I am convinced, because we know all there is to be known on the subject. The subjective symptoms are tinnitus and deafness, peculiar in that they are of sudden onset, especially the deafness. Hearing is generally lost in both ears, though frequently in but one. Unilateral facial paralysis is a not infrequent phenomenon.

S. Latimer Phillips[28] reports the case of a man who, three months subsequent to having chancre on his penis, became suddenly deaf and developed unilateral facial paralysis. In this case it would seem as though the facial nerve and the internal ear were simultaneously overwhelmed in a syphilitic catastrophe.

Syphilis of the labyrinth may occur in hereditary or acquired syphilis. Knapp[1], indeed, thinks that inherited syphilitic disease of the ear is characterized by the preponderance of labyrinthine symptoms over those of catarrhal inflammation of the middle ear. He reports several cases bearing out this view. He refers to the frequency with which syphilis of the brain or eyes is accompanied by aural syphilis.

Mygind,[29] in reporting a case of inherited syphilitic deafness in which ocular manifestations preceded those in the ear, likewise observes that this is frequently noticed in hereditary aural syphilis. The most frequent ocular lesions are keratitis, choroiditis, or iritis.

R. Barclay[30] reports the case of a girl of 12 years who had suffered from syphilitic eye trouble, and for over a year previous to being brought to him had been slightly deaf. Two weeks previous to coming to his office she had suddenly become practically entirely deaf. The child had Hutchinson teeth, and her father acknowledged having syphilis. Barclay says that aural syphilis usually becomes manifest shortly before puberty.

Buck[31] reports the case of a child with hereditary syphilis who lost its hearing in the course of three or four days. Subsequently the child developed syphilitic disease of the eye.

Crocker[32] reported three cases of syphilitic ear disease occurring during the secondary stage of acquired syphilis. All three cases presented very sudden and severe deafness, more or less vertigo and violent tinnitus occurring in persons previously free from ear trouble. He says that this complex of systems should always suggest syphilis, though the same group may sometimes be seen in rare cases of labyrinthine hemorrhage or tumor, and in cases occasionally seen in sudden fixations of the stapes. He mentions as very characteristic of syphilitic disease of the ear, present in these three cases, the following hearing tests: deafness for the watch and voice was marked, a tuning-fork of middle register was wholly lost to bone conduction, but fair for air conduction; the upper register, as shown by the

Galton whistle, was more or less diminished, while the lower limit remained unaltered. He attributes these cases to sudden effusion into the labyrinth, and thinks pilocarpin acts as a specific in them, when given in conjunction with mercury and potassium iodid.

Toeplitz[33] reports an interesting case of labyrinthine syphilis following pharyngeal syphilis and unaccompanied by any middle-ear lesion.

Theobald[34] saw a case of what he regarded as labyrinthine syphilis in which there were most remarkable variations in the hearing power, sometimes quite good, at other times almost nil. This has been noted as a feature of syphilitic deafness by several other observers.

G. A. Syme[35] reports two cases of acquired syphilis in which there was sudden loss of bone conduction, with staggering gait, and tinnitus, which showed marked improvement under large doses of potassium iodid. Buck long ago pointed out the fact that when the auditory nerve was involved it was usual to speak of affections as labryinthine syphilis, whereas. as a matter of fact the auditory nerve may be involved before its entrance into the labyrinth.

Roosa[36] advanced the statement that the most frequent seat of the lesion causing sudden loss of hearing in syphilis was to be found in the conducting apparatus and not in the labyrinth. In a later paper[37] he reiterated his opinion, and gives the following conclusions regarding suddenly developed deafness in connection with syphilis: "1. Very great impairment of hearing occurring suddenly, and not to be explained by the conditions found in the auditory canal or middle ear, so far as we can examine them, and not relieved at once by mechanical treatment, whether occurring in the course of syphilis or not, probably depends upon a lesion in the labyrinth or in the auditory nerve. 2. Absolute or nearly absolute deafness, the inability to hear certain tones, are symptoms of either primary or secondary lesion of the labyrinth. 3. If the tuning-fork be heard very feebly or not at all when placed upon the skull, or if it is heard better through the air than when placed upon the bones, it is probable that there is disease of *the labyrinth*. 4. Syphilitic disease of the labyrinth, if vigorously attacked by means of mercury and iodid of potassium *soon* after the beginning of the disease, may often be alleviated and sometimes cured. 5. Pathological examinations of the labyrinth, although not numerous, have already demonstrated that changes may occur, which confirm the conclusions that have been formed from clinical investigation."

W. Downie[38] describes the lesions found at autopsy in a boy of 17 years, the victim of inherited syphilis. The boy had had syphilitic manifestations in the eyes. Deafness came on gradually for about six months, but total loss of hearing occurred very suddenly. At the post-mortem the external auditory meatus was normal, the membrana tympani thin and free from adhesions, and the malleus and incus in healthy condition. The stapes, however, was "incorporated with, or ossified to, the border of the foramen ovale, and so had become immovably fixed to the wall of the tympanum." The mucous membrane of the tympanum was normal. The internal auditory meatus at its inner extremity was of average normal caliber and both the auditory and facial nerves were healthy, but on tracing it outward at 1 cm. from the inner opening, the upper wall became suddenly thickened, encroaching on the canal, and at a farther distance of 3 mm. the canal was almost entirely obliterated. The vestibule was so greatly encroached upon as to make it doubtful whether any portion of this space remained. The cochlea was of average size, but the modiolus and lamina spiralis ossea were so thickened as to occupy an unusually large proportion of the cavity of the cochlea. Of the semicircular canals there was left only a trace of the external, the rest of this portion of the labyrinth being lost in an ivory-like mass of bone. This agrees with Burnett's[39] statement that the lesion in syphilitic disease of the labyrinth is a sclerosis of the petrous portion of the temporal bone, with ankylosis of the stapes in the oval window, accompanied by thickening of the periosteum of the vestibule and the footplate of the stapes, with hyperplasia and infiltration of small cells into the connective-tissue supports between the membranous structures in the labyrinth and the wall of the bony cavity containing them. The round-cell infiltration may be disseminated throughout the periosteum of the lamina spiralis ossea, the zona punctata and the organ of Corti.

Crockett,[32] in reporting some cases of suddenly acquired syphilitic deafness, says of the pathological conditions found, that we commonly find changes in the periosteum about the footplate of the stapes and the cochlea in the vicinity of the latter, and also degenerative tissue changes in the nerve-cells and blood-vessels of the cochlea. From clinical evidence he attributes the sudden deafness to effusion in the labyrinth.

J. Baratoux[40] records the results of 43 autopsies on infants and children suffering from inherited syphilis. In these he found syphilitic lesions of the middle ear in 27, of the labyrinth in 4, and of both middle ear and labyrinth in 12. When the middle ear and internal ear were both affected, without pus formation in the internal ear, there was vascular injection and cellular infiltration of the soft parts of the labyrinth, the ampullæ and semicircular canals, and instead of the normal liquid of the canals, the parts were bathed in a serosanguinolent fluid. When the internal ear alone was affected, the changes were more marked. The caliber of the vessels was diminished by cellular proliferation in their walls, and sometimes they were obliterated by fibrinous clots. In some instances the labyrinth was markedly congested and there were hemorrhagic areas on the membranous portion, thus proving that the internal ear may be the seat of hemorrhage in hereditary syphilis. From the therapeutic point of view, the only thing of real value is to push the constitutional treatment of the patient, varying between mercury, potassium iodid or the mixed treatment, according to the stage of the disease in which the patient is seen. At one time pilocarpin was highly lauded in syphilis of the internal ear. Risk[41] and others reported cases which had been benefited by its use. At present it is practically abandoned. Of course, if there is suppuration of the middle ear, or ulceration of the external auditory canal, local measures must be added to the specific treatment.

PREVENTION OF INTRACRANIAL AND INTRAVENOUS COMPLICATIONS IN SUPPURATIVE DISEASES OF THE EAR.*

J. H. WOODWARD, B.S., M.D.
NEW YORK CITY.

The predominant task of modern otology has been the evolution of an efficient treatment for mastoiditis and its complications. Formerly, surgical interference with the mastoid region was regarded as a formidable undertaking. In these days, however, we are accustomed to reports of mastoid disease in which cerebral abscesses have been evacuated, thrombosed intracranial sinuses opened and obliterated, and the internal jugular vein removed. Such cases exemplify surgical achievements of the highest order. We must not be dazzled by them, however, for it is a fair question whether there should be any cases of otitic cerebral abscess, or of otitic sinus-thrombosis, or of otitic pyemia. It seems to me that such complications are preventable, or, at least, that they may be relegated to the category of rare occurrences. The following observations are submitted as a contribution to the discussion of the ways and means by which the supervention of these complications may be obviated.

Clinically, every otorrhea should be regarded as a consequence of invasion of the chambers of the middle ear by infective micro-organisms. It is the most obvious and persistent sign of local infection. In thinking of the middle ear, most of us are apt to fix our attention upon the tympanum. But we should remember that the antrum and the cells of the mastoid process are also component parts of the middle ear. It is inconceivable that an inflammatory process, either acute or chronic, should be limited to the drum. It is not to be supposed that the tympanum may be inflamed, while the antrum, lying adjacent, and having the same vascular supply, and the same innervation, and a lining membrane of the same nature, remains unscathed by the disease. Moreover, it is highly probable that the mastoid cells are more often invaded than we are accustomed to believe. These things being true, it is evident that we must search for the sources of an otorrhea, not only in the drum, but also in the antrum, and in the cells of the mastoid process.

Gross inspection of the parts involved in suppurative diseases of the ear shows the lining membrane of the tympanum, antrum and mastoid cells engorged with blood, swollen and softened, in the acute stages, and converted into fungous granulation tissue in the advanced stages of the disease. The underlying bone is inflamed; it is commonly in a state of caries. The changes in the mucous membrane and in the bony walls may present every degree of intensity, and every stage of progress. Pus-formation may be marked, or it may be insignificant. Cholesteatomatous masses are often present in the chronic cases. Almost without exception, the first outlet for the discharges is by the auditory canal through the ruptured membrana tympani. The disease may spread, notwithstanding such drainage, however free, to the intracranial as well as to the extracranial structures. It may extend in two ways: 1, by erosion of bone in continuity; and 2, by escape of the infectious agent from the middle ear through the blood-vessels, or by the apertures in the bones, or through the lymphatics. The bone separating the chambers of the middle ear from the cranial cavity, or from the external world, need not be deeply eroded.

Every one who has critically examined the chambers of the ear in the various stages of chronic purulent otitis media must be convinced of two things: 1, the doubtful probability that advanced disease may be permanently controlled by treatment through the external auditory canal; and 2, the eminent desirability of a permanent eradication of the infective inflammation.

Experience demonstrates that if we wish to prevent the spread of infection from the middle ear to the intracranial regions, the conditions on which the otorrhea depends must be removed. After extension of the infection has occurred, it is generally agreed that operative interference should be undertaken. Also, when swelling with fluctuation develops behind the auricle, no physician would object to an operation. But in the absence of those reasons for operating, which even the uninstructed are able to appreciate, it is customary to recommend palliative measures, rather than resort to means which will permanently remove the focus of inflammation. Although in certain recognizable cases the simpler means will succeed, it is not good judgment to favor a prolonged trial of any method of treatment that is not producing palpable results.

In the majority of cases the objective symptoms will guide us aright in deciding upon the prophylactic operation. I shall ask you to consider, *seriatim*, seven objective indications for the mastoid operation, which may be recognized by the general practitioner.

1. Bulging of Shrapnell's Membrane, with Swelling at the Inner Extremity of the Auditory Canal.—The upper posterior quadrant of the membrana tympani is known as Shrapnell's membrane. Whenever, in purulent otitis media, it bulges into the auditory canal, and especially if swelling at the inner extremity of that canal be associated with it, we may assume that the mastoid antrum is seriously involved, and that the radical operation will probably be necessary to the patient's recovery. It is generally agreed that a free incision should be made through the drum-head in every case. Too great faith may be based on that treatment. The pus is always thick and tenacious, and it may not flow readily, even through a large aperture. Retention of pus in the ear can not be regarded too seriously; and, whenever incision of the drum-head fails to establish efficient drainage, it will be more prudent to open the mastoid antrum at once, rather than subject the patient to the dangers of delay. Those dangers are especially great in diphtheria, scarlet fever and influenza.

---

* Read before the New York County Medical Association, April 16, 1900.

The following history of a case will illustrate some of the prominent features of acute purulent otitis media:

M. O., 29 years of age, consulted me in February, 1899, for inflammation in his nose and throat. He had never had trouble with either ear. There was marked chronic dilatation of the submucous blood-vessels over both inferior turbinated bones; enormous posterior turbinal hypertrophies were present; and his entire pharynx was subacutely inflamed. About two weeks later, he had an attack of acute purulent otitis media in his left ear. Swelling at the inner extremity of the external auditory canal occurred early. The drum-head ruptured spontaneously before he returned to the dispensary with the ear inflamed. After ten days' treatment as an out-door patient, he was admitted to the Metropolitan Throat Hospital, where he remained about a week. The ear having improved, he was permitted to resume his indoor work. The inflammation relapsed almost immediately, and he was readmitted to the hospital on March 21, 1899, suffering from very severe pain in the ear. The mastoid process and the upper portion of the sternocleidomastoid muscle were very tender. The discharge from his ear had diminished, and he had had two mild chills. His temperature was 100. His general appearance was that of great suffering.

On March 22, assisted by Drs. C. J. Strong and E. M. Alger, I opened the mastoid cells, and established communication with the tympanum through the antrum. Pus was found in the inferior cells especially. The diseased mucous membrane and bone having been removed, the entire region was thoroughly disinfected and dressed antiseptically.

On the eighth day, the first redressing was made. There had been no discharge from the wound, or from the ear; and the wound was apparently healed throughout. On the eleventh day, the wound was perfectly healed, the ear was perfectly dry, and the dressings were removed permanently. On April 16, the ear had not discharged since the operation; the scar over the mastoid was normal; and the hearing for the watch, in the operated ear, was 10/30.

Since then, his ear has not troubled him, and the hearing remains as acute as in April. I removed, as soon as possible, the posterior turbinal hypertrophies, and reduced the inflammation in his nose and throat. I saw him in January, 1900, and up to that time the ear had not relapsed.

The result of operation in this case was not an extraordinarily fortunate one. Similar results may be attained with regularity, provided that the operation be thoroughly done, the parts thoroughly disinfected and properly dressed, each time with complete antiseptic precautions, for chance cuts no figure in the healing of wounds made for the relief of pyogenic infective diseases.

Two cases of acute purulent otitis media, in which no operation was undertaken, made a profound impression on me some years ago. Both patients were in vigorous health until attacked by the aural inflammation. Both were exposed to cold after the disease had been running about ten days. One developed typhoid symptoms immediately and died, it was said, of typhoid fever. The other died suddenly on the morning of the day appointed for the mastoid operation. Both lives could have been saved by different management.

In the case of M. O., exposure to cold and fatigue had an evil effect on the otitis. But my previous experiences with similar cases that had not been exposed to cold or fatigue were not very different. Many such might be cited in which bulging of Shrapnell's membrane and swelling at the tympanic ring occurred early, which were treated by the most approved non-operative means advocated by the recognized authorities, but without satisfactory result, and in which, after unnecessary delay and loss of strength, the radical operation became essential to the patient's recovery. In the light of these confessions, it must be evident that I have been conservative in accepting the teachings of experience. But it is plain to me now that the earlier the diseased regions are opened and disinfected, the more speedily will the cure be wrought, and the more safely.

2. Persistent Tenderness over the Mastoid Process.—Persistent tenderness over the mastoid process is a symptom of an otitis having important proportions. It is an indication for the radical operation, in both acute and chronic otitis media. In some such cases we find very little pus. There are otologists who object to a mastoid operation unless one may be confident of finding pus. If by that they mean to imply that there must be more than a few drops of pus in the antrum before they will consent to operate, I can not agree with them. As before stated, we find in purulent otitis media the mucous membrane of the middle ear in a state of fungous granulation, and we find caries of the bony walls of the middle ear. Both of these pathological conditions are incited by infective micro-organisms; and in both the existence of pus may not be very evident on cursory examination. Nevertheless, in order to cure such states of mucous membrane, and to check the progress of the caries, and to remove the infective organisms from the chamber of the middle ear, an operation that penetrates to and eradicates all of the disease must be undertaken. We should not expect other measures to succeed. Our duty to operate, therefore, is quite as great before an abscess has formed as it is afterward.

3. Swelling of the Soft Parts over the Mastoid Process.—The mastoid antrum should be opened in suppuration of the ear whenever swelling of the tissues over the mastoid process is observed. In a certain percentage of cases, incision and drainage of the superficial abscess is followed by recovery. This fact makes it less easy to convince an important body of general practitioners that it is not sufficiently effective. Ten years ago I was willing to handle certain cases in that way. Some of the patients were restored to health after a longer or a shorter period; but in a number of them the radical operation had to be done before the patient could recover. Among those cases of imperfect primary operation was one in which the sequel was disastrous; for my patient subsequently developed a cerebellar abscess, from which he perished. The intracranial complication did not arise until nearly two years after the first operation; but it is certain that had a radical operation been done in the beginning he would not have died as he did.

Mastoid abscesses are due to the spread of infection from the antrum and cells. In order that the infectious agent may reach the periosteum, the intervening bone need not be carious, for it may pass to the exterior through the veins, or the pores in the bone, or the masto-squamous suture. When an aperture through the external table of the mastoid is found, it should never be assumed that further operative interference may be omitted. And, also, when the external table of the mastoid process appears to be in good condition in these cases, we must never imagine that a thorough operation is not essential.

Swelling of the soft parts over the mastoid process, without abscess, is also an indication for an early operation. Such swelling may be dissipated, in certain instances, by non-operative means; but it is not probable that the infective agent may be driven from the field in that way. It is especially important that the radical operation be performed early in cases of chronic suppuration of the ear with swelling over the mastoid. Subsidence of the swelling in such cases can never signify that an adequate impression has been made on the disease, unless the improvement has been brought about by measures that are distinctly more effective than the usual local treatment.

4. Granulations and Fistulæ in the External Auditory Canal.—Granulations and fistulæ in the auditory canal external to the drum-head are indicative of caries in the walls of the middle ear. The discharge in these cases is more or less offensive. The extent of the carious process is not indicated by the objective, much less by the subjective symptoms. And no variety of treatment less heroic than a thorough mastoid operation offers any prospect of recovery. The following history of a case of this sort illustrates the various points commonly observed:

G. F., 9 years of age, was brought to me on account of a chronic offensive discharge from her left ear. The first purulent discharge from the ear occurred when she was seventeen months old. In 1893, she was operated on at the Manhattan Eye and Ear Hospital, and some dead bone removed through the auditory canal, I suppose, for there was no scar over the mastoid. She was under treatment until 1896. The ear had discharged offensive pus for one year when she was brought to me. For a considerable period, her general health had been poor; she was listless, and complained of frontal headache. The ear was discharging freely; and from the upper wall of the auditory canal near the drum-head projected a large granulation. There was neither swelling nor tenderness over the mastoid. At this examination in December, 1899, a large adenoid was removed from her nasopharynx.

A few days later, I attempted to anesthetize this patient; but, owing to her feeble condition, the unavoidable presence of food in her stomach, marked irritation of the bronchial tubes produced by the ether, and the subsequent depressant action of the chloroform, which was finally substituted for the ether, the child's symptoms became so alarming that I was compelled to postpone the work on her ear until another time.

During the following month, she was given iodid of iron and nux vomica. On January 10, 1900, assisted by Drs. C. J. Strong and M. C. Twitchell, and in the presence of Prof. E. D. Fisher, the patient was chloroformed, and I opened the mastoid antrum, which was found under about 1 centimeter of firm bone. There was a small quantity of pus in the antrum; the mucous membrane of the various chambers of the middle ear was in an advanced state of fungous granulation, and the walls of the antrum and cells were carious. Quite an extensive excavation was required to eradicate all of the disease. Very large granulations were removed from the tympanum. The malleus was extracted, and I intended to remove the incus, but it was missing. Nearly all of the posterior wall of the auditory canal was removed, and it was necessary to use the curette freely on the superior wall of the canal. I did not find that the roof of either the tympanum or the antrum had become carious. Finally, the entire region was thoroughly disinfected and dressed antiseptically.

Dr. Strong made all the subsequent dressings, and I did not see the patient again until five weeks after the operation. Then I found the wound entirely healed and the ear dry. The general condition of the child had improved greatly. My object in referring to this case is especially to show how dangerously extensive the middle-ear diseases may be, and yet give rise only to symptoms that are commonly regarded as insignificant.

5. Persistent and Relapsing Fistulæ behind the Auricle.—Persistent and relapsing fistulæ behind the auricle should be cured by a radical operation. They point to the existence of caries of the walls, and an infected state of the mucous lining of the tympanum, antrum and cells. Fistulæ that discharge for a time and close for a period are perhaps more likely to be followed by sinus-thrombosis, or some other intracranial mischief of a dangerous character than are others that remain open continuously. The indications for early operation seem clear.

6. Persistent, and Especially Offensive, Otorrhea.—Persistent and relapsing otorrhea, especially if offensive, ought to be checked by thorough removal of the underlying infective condition in the middle ear. Failure to cure otorrhea by radical operation will be observed rarely, if the work be done thoroughly, and if the wound be kept surgically clean until complete healing has taken place. There may be cases of purulent otitis media that are incurable. There are cases that will not yield to one operation, because all of the disease and all of the infective material may not be removed at the first attempt. The cases that prove to be incurable, and those that prove to be difficult, are either cases in which the infection has eaten its way slowly along for years without any very marked outbreaks, like a smouldering fire in the forest, or they are cases in which the infection is intense, and the attendant indifferent to the dangers of delaying operative interference.

In the winter of 1898, Dr. W. N. Platt, of Shoreham, Vt., sent me a patient who had been under treatment for insane delusions at the State Asylum at Waterbury, Vt. She had a chronic otorrhea, which the doctor conjectured might have had some etiological bearing upon her mental state. The only local symptoms existent when I saw her were a purulent discharge from the ear and slight tenderness over the mastoid process. I operated on her at the Mary Fletcher Hospital, at Burlington, Vt. I found the usual degeneration of the mucous membrane of the chambers of the middle ear. The patient made a satisfactory recovery from this operation, and then her ovaries were removed. The combined results of these operations were good in every way; but inasmuch as the laparotomy succeeded my work so shortly, the psychological value of the operation on the ear was necessarily obscured. However, it is interesting to know that the result obtained was not fugacious. Under date of Feb. 24, 1900, Dr. Platt wrote me as follows: "I had a report from the patient that you operated on for disease of the antrum and cells, last September. At that time, both her mental and physical conditions were good—the normal psychical life perfectly adjusted."

I have referred to this case especially because, so far as I know, the chief reason for removing the disease from the ear, namely, to restore the function of the mind, was unique.

Influenced more or less by the outcome of this case, Dr. George S. Bidwell, of Waterbury, Vt., formerly assistant physician in the state asylum, referred Mrs. Charles H. N. to me for a similar operation. I operated on her at the same hospital in the summer of 1898. The same local symptoms were present as in the other case, and I found in the chambers of the middle ear similar pathological conditions. Under date of Feb. 21, 1900, Dr. Bidwell wrote me as follows respecting this patient: "She had never been adjudged insane, and when she came to you she was able to preside over her children and household. At the time she came, she complained of a strange feeling in her head—that is a term often used by melancholic and maniacal patients in the incipient stages—and confusion of ideas. This confusion was so marked that she was hindered in her household duties. She was annoyed by, and complained of, it. I did not like these prodromes. The otorrhea offered a clue. You restored her. What might have developed in her case we can only conjecture. I firmly believe more serious mental disturbances might have supervened. All abnormal mental disturbances above referred to were relieved by the operation, and four weeks ago she was well, in good spirits, and happy."

It has been suggested that persistent offensive otorrhea should be treated by removal of the malleus and the incus. That is very good as far as it goes. The fact is, however, that if we confine our attention to so narrow a view of the pathology of mastoid disease, we shall fail to relieve many patients who may have caries of the ossicles, but who have at the same time that which is more important, namely, caries of the walls of the antrum and cells. There can be no reasonable doubt that the malleus and the incus should be removed in a certain number of cases of chronic otorrhea, but, as a rule, their removal should be a step only in the radical mastoid operation.

7. *Sudden Marked Diminution, or Absolute Cessation,* of a chronic otorrhea is a symptom of great significance. It should be regarded as the signal that the infection has attacked, or is about to attack, a vulnerable part. It is a command to operate in the most thorough manner, with the least possible delay. In such cases the sigmoid sinus ought always to be explored.

THE RADICAL MASTOID OPERATION.

Macewen, in his classical treatise on "Pyogenic Infective Diseases of the Brain and Spinal Cord," has discussed the radical mastoid operation in the most satisfactory manner. Experience in the operating-room and at the dead-house has demonstrated beyond a doubt, to my mind, that his advice respecting the operative management of mastoiditis and its complications is perfectly trustworthy. It would be impossible for me to add anything thereto. But it will not be amiss to refer to the fact, so frequently forgotten, that the object of the mastoid operation is not to drain the inflamed chambers of the middle ear. The object of the operation is to remove the disease. After that has been accomplished there will be nothing to drain away. In the class of cases under consideration, it is necessary to remove the disease from every recess to which it has penetrated. Not only should the antrum and the cells be freed of the infection, but the tympanum should always be thoroughly curetted, and the malleus and the incus should be removed when they are in a state of caries. Sufficient bone must be cut away to give the operator an opportunity to ascertain the precise condition of the various parts. Objection may be raised against this doctrine on the supposition that such radical invasion of the middle ear will prove disastrous to its function. So far as may be compatible with the well-being of the patient, I agree that the integrity of the ear should be conserved. But the handling which I have advised for the tympanum, however rough it may appear to be, does not necessarily injure the hearing. Whenever the ossicles are so diseased that they must be removed, we shall find that the function of the ear had been destroyed some time before that operation was undertaken. Repeatedly have I demonstrated the fact that the most thorough curetting of the middle ear is not incompatible with the preservation of acute hearing. The following history of a case upon which I made that operation twice within the year is apropos.

H. W., 14 years of age, was seen in consultation with Dr. R. N. Disbrow, on Feb. 21, 1899. During the two years preceding, he had had recurrent attacks of suppuration in his left ear. The discharge had ceased each time after a little, and had never been accompanied by much pain. On February 12, the discharge recurred, and the ear was painful. On the 19th he consulted his physician. On the 20th, he had a chill and his temperature rose to 104. I saw him in the afternoon of the next day. There was some purulent discharge from the left ear; the external auditory canal was free; there was a small perforation through the drum-head, and marked bulging of Shrapnell's membrane. There was no swelling over the mastoid, nor was there tenderness excepting over the knee of the sigmoid sinus. The internal jugular vein was not involved. Mental hebetude and photophobia were well marked. The patient was chloroformed, and I made a free incision through the membrana tympani, but did not evacuate much pus. After the incision had been made, a well-marked transient spasm of the left side of his face, especially about the lips, was noted. On Feb. 22, 1899, assisted by Drs. Disbrow, Booth, and E. M. Alger, I opened the mastoid antrum. It contained pus and fungous granulations, as did also the tympanum. The tympanum and the antrum were curetted very thoroughly, until I was satisfied that all of the disease had been removed. While curetting the aditus, twitching of the same side of the face was observed once. Following up the disease, I was lead to open the sigmoid groove at the knee, and evacuated thereby about two drams of foul-smelling pus.

Ophthalmoscopic examination immediately prior to the operation showed the media clear and the fundus normal in each eye.

I did not see the patient again until Oct. 27, 1899, when his father brought him to my office, having already visited the Eye and Ear Infirmary, where he had been advised very properly that another operation was necessary. I found the ear discharging pus, and there was a fistulous tract opening at the upper end of the mastoid scar and leading down to the antrum. The wound had become infected, and had never healed.

On Oct. 30, 1899, at the Metropolitan Throat Hospital, assisted by Drs. C. J. Strong and John Drew, and in the presence of Dr. E. M. Alger and others, I operated again on this patient. The antrum and the tympanum were full of granulation tissue and cholesteatomatous masses. Very thorough curettage of the tympanum and antrum cleared away all of the disease. The only invasion of the bone consisted in a small spot of caries in the lower portion of the mastoid process.

On November 2, I redressed the wound, and removed a large adenoid from his throat. On December 2, all dressings were permanently removed. There was a large polypus projecting from an aperture in the drum-head. By December 6 the last vestige of the polypus had been destroyed. About December 20 he was discharged cured. There had been no discharge from the ear since the polypus had been exterminated. The hearing for the watch in the left ear, the tympanum of which had been curetted twice within the year, was normal, or for my watch, 30/30.

The dangers incident to the radical operation on the mastoid in uncomplicated infectious diseases of the middle ear have been grossly exaggerated. Irregularities in the anatomy of that region have been supposed to be common enough to endanger the important closely adjacent parts, and even the patient's life, during the operation. Such suppositions are purely fanciful. It is true that the operator may wander from the course which he should follow; but it is futile to ascribe the error to an alleged anatomical peculiarity of the patient. Moreover, even after thorough eradication of the infective process, the most radical antiseptic measures are essential. Efforts to secure and to maintain thorough disinfection of all the parts involved must not be relaxed until the wound has healed perfectly.

In conclusion, permit me to remind you of the importance of diseases of the nose and throat as predisposing causes of suppurative diseases of the ear. The existence of hyperplasia of the lymphoid tissue in the vault of the pharynx tends to provoke acute suppuration in the middle ear, and provides a condition favorable to recurrences of the attack. Attention has been directed to this fact by numerous writers, but the lesson has not been learned even by many who are pretentious of being known as specialists in otology. Among close observers there can be no doubt that, in patients under 15 years of age, an adenoid exists in almost every case of suppuration of the ear. To have any etiological bearing, however, it must promote a chronic congestion of the nasopharynx. In order to serve that purpose, the growth need not be very large, although the greater the adenoid, the more likely will it be to cause trouble in the ears.

Associated with adenoid growths, we commonly encounter a hypertrophy of the faucial tonsils. At the same time, a hypertrophic rhinitis, in which chronic dilatation of the submucous veins of the inferior turbinal body plays the chief rôle, is the prevailing obstruction in the nasal passages.

Posterior turbinal hypertrophies, likewise, obstruct respiration through the nose, and they, too, should be enumerated among the predisposing causes of purulent otitis media.

In view of these facts, it must be obvious to all that rectification of abnormal states of the nose and throat is an indispensable preliminary to the prophylaxis of intracranial and intravenous complications of infectious pyogenic diseases of the ear.

THE CEREBRAL NEURONS IN RELATION TO MEMORY AND ELECTRICITY.*

SIR JAMES GRANT, K.C.M.G., F.R.S.C., F.R.C.P. Lond.
OTTAWA, CANADA.

Professor Heger,[1] of Brussels, gives an account of experiments made on animals to determine the conditions of the brain cells, during various conditions of rest and stimulation, and concludes that "an important property of the cerebral nerve cell is its variability in reaction as regards its cell body, its processes, and its epidendritic granules. Changes in all three portions may co-exist or occur separately under different conditions, the further significance of which is important, and demands investigation." The nervous system reduced to its initial stage may be represented by two elements, a nerve cell, and a conducting tube, and it is the association of these two elements, which constitutes nerve centers and nerves. *Punch* tritely remarked, "What is matter never mind, what is mind, that's the matter." Although no relation of identity or analogy subsists, between mind and matter, a close relationship may be shown to exist between mind and force, or between mind force and nerve force. Undoubtedly mental activity may be excited by nerve force, and such is found to be the case in every act in which the mind is excited through the instrumentality of sensorium. The will can develop nerve force, and as a nerve force, can develop mental activity. There is in fact, a correlation between these two forces, fully as intimate as that which exists between nerve force and electricity. Maudsley is of opinion, there is memory in every nerve-cell, and indeed in every organic element of the body. The organic registration of the results of impressions upon our nervous centers, by which memory is established, is after all the very basis of mental life, and the cells and nervous tubes, associated in many ways, constitute the nervous system in its entirety. As life progresses tissue formation changes materially, and we gradually observe the outward as well as the inward manifestations of declining activity. Such is observed in the loss of hair, and the bald scalp, in the decay of teeth and consequent defective power of mastication, so also in the defective auditory process, as well as in gradually impaired vision and memory. Such evidences are undoubted in their character, and positive proof, should such be wanting, of an abnormal decline in systemic power, coincident with advancing years. While these systemic evidences of change are in progress, it is reasonable to infer that nerves and nerve centers, the very motive power of the entire system, should also participate in some degree in those structural modifications, indicative of molecular change, and impaired functional activity. Recent discoveries in the line of nerve-tissue formation, have defined small cellular almost rod-shaped bodies, as components of cell nervous tissue, known as neurons, which take an important place in the elimination of nerve power, and contributing to the production of normal functional activity. One of the most interesting developments recently announced in Germany, France and America, is that nerve cells were capable of movement, to such an extent as to actually alter their original relationship one to the other. In 1890, Wiederschein, a German physiologist, saw in the Leptodara Hyalina, an invertebrate, one of the entomostraca, the nerve cells of the esophageal ganglion move in a slow flowing fashion. This altered relationship almost molecular in character, may give a clue to a lessened functional activity and constitute the basis on which retardation rests. This constitutes the field of action, as to the therapeutic power of the electric current, which, as a known force, is still in its infancy. At the convention of the American Electro-therapeutic Association,[2] it was stated that static electricity causes contraction of the protoplasm, both animal and vegetable, excites nerve fibers, nerve centers, and nerve cells, to functional action, and to produce their separate effects, motor, sensory, secretory, sympathetic and vasomotor. The recent observation of Professor Herdman,[3] of the University of Michigan, is as follows: "That whenever a current of electricity traverses an animal body, the magnetic field resulting from the current and surrounding its path, must disturb in some manner the molecular and atomic activities that are going on in the tissues and fluids, through which the current of electricity passes, in fact, in such a manner as to rotate in some degree every molecule, so as to make it assume a different position from what it would if not thus acted upon," and draws the deduction, "that alternating magnetic stress is in some way related to quickened metabolism of tissue; that the magnetic energy goes through some sort of transformation, and reappears as physiological energy." During the past few years, in noting the results of failing nerve power, as indicated by functional inactivity, in tissues and organs generally, I have been more and more impressed with the vast importance of a thoroughly established balance of power in each structure of the human body and particularly with reference to the nervous system. In the examination, no organ should be passed over casually, or even section of the body, as difficulties creep up almost silently and diseased conditions become established prior to particularly marked external indications of importance defining the same. The brain is the battery of the body and as diversified in its peculiarities and manifestations as the facial expression of the Genus Homo, no two of the entire human species being exactly alike. In the examination of nerve power by electro-neurotone currents. I noted on several occasions after a few weeks' application quite a change in intellectual activity, as evidenced by improved memory. The currents were passed through the base of brain chiefly, by applications to the parotid regions on either side of the neck, and in the most casual manner, not in the least anticipating this practical result. The individuals operated on were over 60 years of age, and the improvement of memory was of such a character as in my humble opinion to be worthy of the closest scientific inquiry.

REPORT OF TWO CASES OF AFEBRILE TYPHOID.

CHAS. J. WHALEN, M.D., LL.B.,

CHICAGO.

I presume no one thing has aided us so much in the diagnosis of typhoid fever as the temperature chart. Since the use of the clinical thermometer the temperature has come to be the indication for diagnosis, treatment and prognosis. All the old and recent authorities place great emphasis on this symptom of the disease. Indeed, the temperature in typhoid is so absolutely essential for the estimation of each individual case that no scientific physician would treat one without regular measurements of the temperature.

It was formerly considered that typhoid fever had to be accompanied by elevation of temperature, and the rule that at some period of the disease the temperature is raised was supposed to be without an exception. That such a thing as afebrile typhoid exists has been called to the attention of the profession by Liebermeister. I shall not enumerate the symptoms of this disease, but I wish to show that we may have absence of rise in temperature and yet the case be one of typhoid fever. Within the last few years I have seen patients with undoubted afebrile typhoid, and this has led me to give the subject consideration. My investigation has convinced me that the disease does occur in an endless number of types, and in this connection I desire to call attention to two cases of the afebrile form which came under my observation during the last sixteen months.

CASE 1.—J. E., a clerk, aged 23, whose previous health had been excellent, came to me Sept. 10, 1899, complaining of lassitude, headache, inaptitude for work, constipation quite pronounced, and loss of appetite. The above symptoms had been present for five days, and there was no temperature, but some splenic tenderness. He was given a cathartic with instructions to call again within forty-eight hours. At the end of this time he complained of having had a severe epistaxis on the morning of the sixth day, no temperature, the tongue dry and coated, and tenderness over the spleen more pronounced. I found both the diazo and Widal reactions positive, and this at once confirmed my suspicion of typhoid fever. On the eighth day there appeared a crop of five distinct rose spots. On the tenth there was quite marked iliac tenderness and meteorism present; the pulse was soft and beating 100 per minute. The patient was put to bed, where he remained for three weeks, and during this time his temperature was taken four times daily and the highest degree recorded was 99. At the end of this time the patient was told that he might go home, but that he was to follow out instructions regarding diet, exercise, etc. On arriving home he disobeyed and partook of a large meal, walked several miles, spent the day and evening in visiting friends, and the following day felt weak and exhausted; on the next day he had headache, no desire for food and felt bad generally. He continued to grow worse, and, five days afterward I found him with mental torpor and dulness, his tongue and lips dry, a new crop of rose spots on the abdomen, and considerable meteorism present, with a large and tender spleen, temperature 102 and pulse 100. This patient, in his relapse, ran a typical course of severe typhoid fever, his temperature pursuing the step-ladder rise and continuing high for four weeks, though he eventually recovered after being in bed two months.

CASE 2.—July 8, 1900, John R., a schoolboy, aged 17, consulted me because of lassitude, intense headache, weakness and gradual loss of appetite, nervousness, inability to sleep and occasional chilliness; he also complained of marked constipation. I found his tongue heavily coated, pulse 106, soft and slightly dicrotic, temperature normal, some iliac tenderness and meteorism present, a crop of rose spots on the abdomen and thorax, Widal and diazo reaction both positive. By July 20 he had improved generally, meteorism had nearly subsided, and he was beginning to crave food, no elevation of temperature had been noted, although it had been taken four times daily after the first visit. From this time on the patient gradually improved, and at the end of three weeks after first consulting me, barring a slight weakness, he was apparently well.

I was taught that typhoid fever had a characteristic course, a step-ladder rise in temperature continuing high for a period ranging from two to four weeks, declining gradually during the third and fourth. I am convinced that we may have genuine typhoid without any rise of temperature. Therefore, the typhoid of to-day is not the typhoid of von Niemeyer, Trousseau, Flint and others, for they portrayed a disease having a fairly constant train of symptoms, a fever with a characteristic course and other equally important conditions varying. Certainly ambulatory and afebrile types of the disease must have been very rare or else were not diagnosed in the practice of the older authors.

34 Washington Street.

A Hospital Steamer for the Philippines.—Major John S. Kulp, surgeon U. S. V., has recently reported the results of a voyage from Manila, on the army transport *Pennsylvania*, to bring sick men from the outlying islands to the general hospitals in that city. The vessel, a Philadelphia built, tripple-expansion, single-screw iron steamer, of 3343 tons capacity, left Manila Oct. 5, 1900, with a small cargo of subsistence and quartermaster's supplies and accommodation for the return of 160 sick soldiers. Everything necessary for the comfort, welfare and convenience of the sick was furnished promptly from the medical supply depot at Manila. The bunks were iron-pipe frames with woven-wire mattresses, all on the main deck, well ventilated and high above the water line. The vessel called at eighteen ports and brought off 155 patients, returning to Manila November 11, after a voyage of 2332 miles. Thirteen of the patients were affected with diarrhea, 46 with dysentery, 19 with malarial fever and 10 were sufferers from gunshot wounds. No death occurred during the trip, although many of the cases when received were of a grave character. In every case there was a marked improvement, and many were practically well by the end of the voyage. The object of the voyage was to determine whether or not it was practical to make use of one of the inter-island transports for the transportation of the sick during her regular trips. The result from an administrative standpoint was unsatisfactory. It proved that a ship devoted solely to the interests of the medical department was a necessity. Although the cargo was insignificant in amount the voyage was prolonged one-third on account of the delays caused by its delivery. Col. Greenleaf, chief surgeon of the Division of the Philippines, states that authority has been received from the U. S. secretary of war to purchase a light-draught ship for use as an inter-island hospital transport, and that measures are now on foot to effect this object, which will solve satisfactorily the question of furnishing the provincial military hospitals with supplies and removing their sick when necessary.

SATURDAY, FEBRUARY 2, 1901.

THE DIVISION OF FEES.

Commercialism is not a word in good repute in connection with the practice of medicine. Not that it is wrong for a physician to make money if it is done honorably; nor is it beneath the dignity of an ethical member of the medical profession to apply honorable business principles in obtaining just remuneration for services rendered; but it is wrong, and degrading, for him to subordinate all he may do to commercialism. The making of money is the mainspring of commerce, but medicine, in its scientific as well as in its altruistic ideals, has a higher and nobler aim. The laborer is worthy of his hire, but in medicine the latter is only an incidental, not the ideal, end and aim. If it were, our widely-uttered claims of being a liberal profession are false, and a large proportion of what we may call the non-scientific portion of medical literature, including most addresses to graduating classes in medicine, and to societies, is the veriest talking for effect. Sometimes it would seem that there is too much of this kind of literature—that we protest too much in self-praise—but it keeps us committed to our higher ideals and in that way does good.

If, on the other hand, we come out plainly with the admission of purely mercenary motives in the practice of medicine, we misrepresent our profession, for however much we may deny it, should we care to, the practice of medicine is necessarily a self-sacrificing profession, and at best its average rewards are below what equal talent and industry bring in other occupations. It has, moreover, its scientific side which can not be ignored, and a system of ethics published to the world as a rule of conduct which is throughout antagonistic to any purely commercial estimate of the profession of medicine. We can have, therefore, only the alternative of still publicly repudiating commercialism or of giving up our best professional traditions, which is impossible. Even should we profess to do this, we could not do so in practice, and would not if we could. There is, therefore, no choice in the matter as regards the practice of medicine generally; the question only remains as to the course to be followed in special cases, and as to certain practices that tend toward questionable business methods.

One of these is the giving of commissions. It might naturally be supposed that this is not a debatable question, that such a practice is so opposed to the traditions and to the ethics of the medical profession that there could be but one opinion—and that emphatically against it. That this supposition is not a correct one is evidenced by the facts that: 1, a prominent physician not long ago read a paper before a medical society, in which he advocated a division of the fee; 2, a professor in a leading medical college is reported to have said in a medical society last week, when this question was being discussed, that he was in sympathy with the idea; 3, it is openly charged that certain men are to-day giving commissions to physicians sending them cases. It therefore seems necessary to consider the matter and let it be known whether such a practice is recognized as right or whether it shall be condemned. Therefore, if it is to be condemned, let it be done with emphasis, and not with an ambiguity of expression that will leave a doubt as to what is meant. On the other hand, if it is decided that it is right, let it be known so that we may all act accordingly. If it is right for one it is right for all. And let the people know it, for the patient is certainly interested in the matter and ought to have a clear understanding of the arrangement.

Any receiving of commissions from surgeons or consultants for cases referred to them, without the knowledge of the patient, would be bringing into the practice of medicine methods that would be degrading even in commercial life. It is evident, however, that no patient is likely to permit himself to be exploited in this way if he can help it, and an understanding as to sharing the consultant's fee must inevitably be a secret between him and the practitioner. Thus the transaction, reduced to its simplest expression, means the introduction of the lowest and most disreputable of business methods into the practice of an honorable profession. The right of the attending physician to remuneration for his services does not enter into the consideration of the question. Whatever he is entitled to he should demand and collect from the patient.

That a surgeon sometimes gets a fee quite disproportionate to the small remuneration received by the attending physician is no argument for the division of that fee. While it is unethical to the last degree to make extortionate charges, the wrong is not made right by another coming in and taking part of that which has been obtained unrighteously, provided it has been so obtained. But whether it is right or whether it is wrong can be very easily decided, for the question simply resolves itself into this: Does the patient know of the transaction? If so, then it is legitimate and ethical; if not, it is collusion.

This question has been taken up by the newspapers and, as usual, the medical profession has been misrepresented, misquoted, and maligned. To read the lay press opinions one would suppose that this commission business is a common practice, but we protest that it is not. What little has been done has been done secretly and under cover, and by but a very few. That it has been done, and by those who claim respectability, can not longer be denied, and there is no use in treating the matter ostrich fashion, for shutting our eyes to it does not prove its non-existence. It is hoped, therefore, that those societies which do take it up will meet the question fairly and squarely, so that there may be no misunderstanding in the future. Let it be known whether the medical profession is merely a money-making trade, adopting the methods, good and bad, of those others with whom money-getting is the sole aim, or whether it is an honorable profession with a well-earned reputation for philanthropy and good deeds, which its members do not propose it shall lose.

MEDICINE OF THE NINETEENTH CENTURY.

Notwithstanding the power that the discovery of the uses of steam and electricity has given to the race; notwithstanding the happiness that education and improved ethics have brought to humanity, the greatest gift that the nineteenth century has given to man has been the discovery of scientific laws that lead to health; laws by the knowledge of which the plague and the diseases of other countries have been kept from spreading through the community, and laws which have taught physicians how to speedily ease suffering and to save and lengthen life.

A masterly and comprehensive syndicate article on "Medicine in the Nineteenth Century," from the pen of Dr. Osler, has just appeared. In it he sums up the discoveries and the advances of medical science in the last one hundred years, and to the layman his lucid descriptions of progress can not but be a revelation.

At the beginning of the last century the theory that "aqueous" and "dry humors" were the seat of disease was still taught. In 1801 Bichat, a young French physician, taught that the seat of disease was not in the organs themselves, but in the tissues of the organs, and thus gave an impulse to the study of morbid anatomy. Laennec discovered the art of auscultation, and his contributions to the study of the diseases of the lung and heart really laid the foundation of modern clinical medicine. Bright's researches on the kidneys and the differentiation of the fevers into typhoid, typhus, relapsing and yellow were the beginning of the original work. Once the idea of scientific investigation took the place of the philosophic discussion of theories, the light began to break, and as it lit up first one source of disease after another, we, who look backward in review, can see how dense must have been the darkness of ignorance before the present century.

In the growth of specialism, while there has, perhaps, been a loss in breadth and harmony, there has been the compensation of greater accuracy in the application of special knowledge. This has been particularly valuable in the diseases which are peculiar to women, especially to accidents incident to child-bearing, and in the great improvement in the treatment of insanity.

At the beginning of the century there were but three medical colleges in the United States and only two general hospitals. It was the custom of practitioners to take students as apprentices, and the well-to-do finished their education abroad. After 1830 a remarkable change took place, owing to the leaven of French science brought from Paris by American students. Between 1840 and 1870 there was a great increase in the number of medical schools, but the standard was low and the work poor, from the multiplicity and rivalry of ill-equipped institutions. However, the evolution of the medical school that followed the reformation, begun in 1868, by raising the standard over the whole country, was one of the most remarkable phenomena in the history of medicine in the United States.

Dr. Osler calls attention to the fact that sanitary science, or hygiene, is one of the bright spots of the century. A knowledge of the conditions of disease, and the means of transmission together with the culmination of the art of preventive measures, has made smallpox, as a dangerous disease, a thing of the past. It has effectually kept cholera and the bubonic plague from spreading in the country. It has restricted yellow fever to its original localities, and has reduced the death-rate of typhus from 1228 per million—in England sixty years ago—to 3 per million to-day, while it has so conclusively proved the exact precautions that must be observed to prevent typhoid and tuberculosis, that it is only through gross carelessness and wilful lack of sanitary measures that they can spread.

But as he remarks: "Preventive medicine was a blundering, incomplete science until bacteriology opened unheard of possibilities for the prevention of disease." The brilliant overthrow of the hitherto much-discussed theory of "spontaneous generation," by Pasteur, Tyndall, Koch and Cohn, and the tracing of each disease to its bacteriologic origin has been the bright triumph of the century. It has led to a knowledge of wound infection, which has served as the foundation stone of the science and art of modern surgery. It has been the means of determining definitely the cause of leprosy, so that plague may never again obtain a foothold. It has reduced the aggregate death-rate of diphtheria fully 50 per cent., since the discovery of antitoxin, and concerning that most deadly and insidious of human diseases, which Dr. Oliver Wendell Holmes called the "white plague"—tuberculosis—it has taught the origin and means of prevention, that may, if faithfully followed, lead to the eradication of the disease. In summing up the revelations that have been made concerning contagious disease, through bacteriologic investigation, Dr. Osler outlines the fields of investigation that have not yet been worked with success. The cause of contagion of the exanthemata, measles, scarlet fever, chicken-pox, smallpox, and of whooping-cough, though yet unknown, he thinks may be of bacterial origin, but that the special bacteria may be too minute for any known microscope to reveal.

The last word of the century on these lines is concerning serum-therapy, which experimenters are trying for every contagious disease, with effects that will probably modify present lines of treatment within the next ten years. While there has been a remarkable diminution in the prevalence of a large number of all the acute infections, "pneumonia," says Dr. Osler, "not only holds its own, but seems to have increased in its virulence," while concerning venereal diseases, which continue to embarrass the social economist and to perplex and distress the profession, he recommends legislation.

The brilliant experiments of the summer of 1900 on the Roman Campagna, proving conclusively that malaria can be communicated by mosquitoes, and solving at once the mystery of marshy lands, the hot season and the night air, is almost a spectacular ending to the century's work and opens an entirely new field for investigation concerning the relations of insects and animals to human diseases.

One of the striking features of modern medicine, as Dr. Osler points out, is the tendency on the part of physicians to give little or no medicine and to substitute attention to diet, exercise, rest and climate for drugs. And yet the century never witnessed a more perfect and all-abiding faith in drugs on the part of the layman than at its close. But as this man of wisdom concludes, faith is as ever a large element in the success of the practitioner, and, as Galen said, "confidence and hope do more than physic."

THE HEREDITY OF DIABETES.

Despite the earnest study that has been devoted to the subject of diabetes in recent years, the most that can be said with regard to the nature of the disease is that it is the expression of some as yet obscure derangement of metabolism, in consequence of which carbohydrates are not properly assimilated and consumed in the body, and appear in the blood and the urine as glucose. While the affection is sometimes observed in association with organic disease, more especially of the brain, and less commonly of the pancreas, no gross lesion is appreciable in the majority of cases. The derangement of function must, therefore, be referred in many instances to structural, textural, cellular or nutritive alterations, and a mutual relation exists between this assumption and the fact that the disease is sometimes transmitted by heredity. It is estimated that the latter takes place in about 25 per cent. of the cases. Thus, Thomas Oliver[1] cites an investigation by Weil of 90 members of a family through four generations, of whom 21 were certainly and 13 doubtfully diabetic. He also relates of an applicant for insurance that the father, three brothers and one sister had died from diabetes. Other instances are on record in which seven and eight children, respectively, in one family have exhibited diabetes. In a family reported by von Noorden, ten members of four generations were diabetic. J. H. Pleasants[2] has recently reported six cases of diabetes in two brothers, two sisters, an uncle and a great-uncle, among 24 descendants of a common progenitor, of whose urine examination was made in all but one case. Investigation, with the object of shedding light on the question of conjugal diabetes, into the condition of those who had married into the family, yielded only negative information.

A study of the reported cases of diabetes in which heredity appears to have been an etiologic factor discloses certain peculiar features of the familial type of the disease. It is often observed that the disease occurs in an uncle, an aunt, or a cousin, while the parents escape. This may be conveniently spoken of as the "collateral inheritance" of diabetes. In the same way, a grandparent may be diabetic, while the parent escapes. When successive generations are affected, there is a tendency for the disease to develop at a progressively earlier age. When more than two members in the same generation are diabetic, there is a tendency for the disease to appear at approximately the same period of life. While hereditary diabetes developing in the first two decades is often of a severe character, the cases developing later in life are generally of a mild type. In a certain number of cases the disease has appeared in the children prior to its occurrence in the parent. There is frequently a neuropathic tendency in diabetic families. Cases are recorded in which several children were diabetic, while the others suffered from various psychoses. Obesity is often a characteristic of families in which diabetes occurs.

INTOXICATION WITH CREOSOTE.

Creosote is one of the best of the many medicinal agents recommended for the treatment of pulmonary tuberculosis, and in view of the large scale on which it has been employed and the freedom with which it has been administered, it is indeed fortunate that its toxic effects are not more pronounced than they have proved themselves to be. The substance exhibits certain points of resemblance to carbolic acid, by which it is at times contaminated or wholly replaced, and it is possible that some cases of intoxication attributed to creosote may really be due, in part at least, to carbolic acid. Nevertheless, creosote is capable of toxic effects, and occasionally, as some cases recorded in the literature testify, there may be a marked idiosyncrasy to its action.

Creosote, though very pungent, is less escharotic than carbolic acid, but, taken in excess, it gives rise to nausea, vomiting, colicky pain, and diarrhea, with vertigo, obscurity of vision, depression of the action of the heart, convulsions and coma. The soluble sulphates are recommended as antidotes, and in cases of poisoning the stomach should be evacuated and ammonia and other stimulants administered. An instance in which the ingestion of a large amount of creosote on the part of a child was recovered from on the prompt institution of active treatment is reported by Dr. H. M. Hewlett.[1]

---

[1] Lancet, Nov. 10, 1900, p. 1335.

[2] Johns Hopkins Hospital Bulletin, Dec., 1900, p. 325.

[1] Intercolonial Med. Jour. of Australasia, v, No. 10, p. 501.

A girl, 3½ years old, swallowed 2 drams of pure creosote, and immediately complained of abdominal pain. She was at once given a tablespoonful of olive-oil, but soon became unconscious. When seen, twenty minutes later, she was insensible, and the face was pale, the lips cyanosed, the respirations extremely shallow, and the pulse imperceptible. The eyes were fixed, the pupils contracted and immobile, and the extremities cold. The muscles were flaccid, and no difficulty was experienced in introducing a tube into the stomach and practicing lavage, about two quarts of warm water being used. The stomach was then washed out with two pints of strong solution of magnesium sulphate, about six ounces being left in the viscus. Strychnin, 1/25 gr., was injected hypodermically, and the patient was wrapped in blankets and surrounded by hot bottles. A rectal injection of extract of beef and brandy was also given. In about eight minutes after the stomach was emptied the color of the lips improved and the pulse became perceptible. In another ten minutes resistance was offered to the presence of the stomach-tube. The color was now good and the respirations full and regular. The pupils were still contracted, but reacted to light, and the extremities were warm. Improvement continued thereafter without relapse. Pain over the region of the stomach was complained of when a little white of egg and milk was swallowed a couple of hours later, but this was relieved by hot fomentations. Urine was not passed for many hours, and then presented a dark-brownish color. Subsequently the urine exhibited a watery-green and then a pale-yellow appearance. The first bowel movement also was dark in color and smelled strongly of creosote. There were no after-effects, and in the course of a few days the child was running about again and appeared none the worse for her dangerous experience.

MISSOURI'S CHIEF EXECUTIVE.

The *St. Louis Courier of Medicine* devotes a sarcastic editorial to the outgoing governor of Missouri, who appears to have been, from a medical point of view, about all that the chief executive of a state ought not to be. It expresses the opinion that the most sensible thing of which he has been guilty was his congratulations to the citizens, in his last message, that his term had nearly ended. As one of the dispensations of a kind Providence it may be noted that the new Governor of Missouri is a member of our profession, and if he is true to his antecedents the wind will be tempered to the shorn Missouri lamb.

JUDICIAL EUTHANASIA.

While a bill referring to the manner of execution of criminals was recently under consideration by the Indiana legislature, an amendment was offered to inflict the punishment of death by giving 15 grains of morphin in a glass of whisky. This motion failed, though it is reported to have received a full party vote. The Indiana murderers, "like maudlin Clarence in his Malmsey butt," would undoubtedly favor this mode of execution, but why this special zeal for euthanasia for criminals is such a prominent feature in modern legislation is not clear.

WATCH MEDICAL LEGISLATION.

It behooves the members of the medical profession, in the various states in which a legislature is in session, to keep in close touch with what is going on in regard to the regulation of the practice of medicine. In nearly every state more or less vicious medical legislation is being attempted. In Illinois an amendment to the medical practice act is proposed, in which these words occur: "Nothing in this act shall be construed to apply . . . . to any person who ministers to or treats the sick or suffering by *massage*, or by *mental* or spiritual means, without the use of any drug or material remedy." The object of this amendment can be readily seen. In those states where there is no committee officially appointed to represent the profession, such legislation as the above will be easily managed and the profession wake up, when it is too late, to realize the fact that laws have been passed that are detrimental alike to the people and to the profession. When this occurs, nine times out of ten it is the fault of the profession itself, a result of lack of organization and of apathy.

RELIGIOUS RITES FOR THE DYING.

A Roman Catholic paper calls the attention of physicians to the advisability of informing Catholic patients or their friends of their condition when it becomes critical, and in any event not allowing them to die before the church's last offices for the dying can be performed. It was possibly in view of something of this kind that led a Missouri judge to decide that it was the physician's duty to inform the patient of his hopeless condition. There are objections to the unqualified adoption of this course, as THE JOURNAL has already editorially pointed out, but the Catholic editor's recommendation has a much better medical sanction. As he sensibly remarks, the peace of mind that follows confession often causes a change for the better in Catholic patients, and the other rites, as some of us may have observed, may have the same effect. Whatever one's own religious views may be, there is good medical reason for respecting those of others, especially in such cases as these. It is not necessary to infer that such warnings are a practical death-warrant to the patient; for they may, on the other hand, be the means of introducing the most potent of therapeutic suggestions.

IS EXERCISE UNHEALTHY?

Falstaff's opinion, that it is better to rust than to be scoured to nothing with perpetual motion, is echoed to a certain extent by a physician who holds that exercise is unhealthy for men past 35 years of age. He has received a number of endorsements from individuals who, while not Falstaffian in all respects, endorse that hero's philosophy to this extent. Among them are cited Russell Sage, the financier, William M. Evarts, and others who have never exerted themselves physically when they could help it and believe themselves the better for this course. The American people, according to these authorities, are ruining their constitutions by too much activity, and we are told that we should adopt a more restful way of living, at least as regards physical exercise. It would be interesting to exercise one's fancy as to a state of society in which physical inactivity was the rule after 35; it would be a queer world, at least in this latitude. The notion is one of those one-sided ideas that sometimes find expression and are taken up and made the most of by the lay press. This one is comparatively harmless, since there are not many who will believe it, and fewer still who will be able to follow the teaching, as man is constituted and in present social conditions.

THE COCAIN HABIT.

The cocain habit in the South, which has been already noticed by The Journal, seems to be extending. Measures have been taken to stop the indiscriminate sale of the drug in some cities where the evil is most pronounced, and similar ones are advocated in others. The cocain habit is said to have already invaded some northern cities, though in none of them is it as general a vice as among the negroes of the South. In New York some of the physicians interviewed in regard to the habit and its prevalence claimed that medical students were particularly liable to become its victims, others gave quack remedies as the chief cause of its spread, and the mistaken popular notion that it is a cure for drunkenness was also credited as an agency. Men in thus attempting to conquer one tendency become slaves to another, or both, and their last state is worse than their first. It may be that the danger is overestimated, but it is well to be informed as to the possibilities. In any case the sale of cocain should nowhere be unrestricted; this drug as well as morphin should be only obtainable on physicians' prescriptions and careful registry be kept of all sales. Its present freedom of sale in most sections, to any and every one who asks for it, is a special danger that is the more inexcusable as cocain is a comparatively new drug and the vice has not acquired, like that of alcohol, a time-honored common law sanction.

VITAL STATISTICS AND REGISTRATION OF BIRTHS.

In the retiring message of the late Governor of Illinois there were a few recommendations on matters of medical interest. One of these referred to a defect in vital statistics that is perhaps not peculiar to this commonwealth, but is nevertheless one that calls for amendment. This is the more true since the medical profession is in some respects responsible though not altogether without excuse for its neglect. Any one reading the reports of deaths published in the Chicago lay papers would naturally come to the conclusion that the native stock is on the road to extinction, and that obstetrics forms no part of the medical practice of American physicians. Foreign-born midwives seem to be busy delivering mothers with largely foreign-sounding names, and only occasionally, or at least in very inadequate proportion, do medical men appear to have any share in the work. It was said at one time that a prominent and popular suburb, chiefly inhabited by the best American-born citizens, had almost no births reported from its precincts. Nevertheless, the younger generation somehow comes into existence, and in a reasonable quantity. The facts speak for themselves. The vital statistics in most of our states are practically worthless because they are incomplete. It is easier to get reports of deaths, as burial permits require them, but the fully as important event of a birth too often goes unreported simply because it is practically impossible under present conditions to enforce it. Governor Tanner's suggestion is practical in that it considered the need of offering some recompense to the accoucheurs for the trouble of making the report; without that it is likely that statistics will remain imperfect, as only the most rigid police regulation and oversight, such as are hardly compatible with our customs, would enforce the registration.

Medical News.

ARKANSAS.

Dr. James L. Goree, Pine Bluff, for many years president of the local board of health, has resigned.

Dr. Arthur B. Loving, Pine Bluff, has been appointed physician of Jefferson County for 1901, in succession to Dr. William A. Noel, term expired.

The State Legislature passed a law at its last session imposing a fine of $25 to $100 on any dealer found guilty of selling cocain except on the prescription of a physician or to a physician.

CALIFORNIA.

Dr. Thomas B. W. Leland, San Francisco, was appointed coroner of the city and county of San Francisco, January 16, vice Dr. R. Beverly Cole, deceased.

Six surgeons of the Emergency Hospital, San Francisco, were dismissed January 18, the reason given for the change being that the service and efficiency of the hospital would be benefited by limiting the tenure of office to one year.

Dr. Kinyoun's critics have caused a resolution to be passed by the state senate, by a vote of 26 to 8, requesting his removal by President McKinley on the ground of unauthorized quarantine of the state because of "alleged bubonic plague in San Francisco."

A consumptive immigrant from British Columbia, who arrived in San Francisco, January 22, was not allowed to land as he was afflicted with a communicable disease, and was indigent. He will be deported. This is the first instance of the kind in the port of San Francisco.

COLORADO.

Dr. John G. Keith, Leadville, has been elected physician of Lake County.

A brutal assault was made on Dr. Louis Auerbach, of Denver, by highwaymen, recently. His nose was broken and he may lose the sight of one eye.

Vaccinator-in-chief is the title of Dr. John A. Henry, who has been appointed to supervise the work and inspect the results of the compulsory vaccination recently ordered in Denver.

Denver Physicians, who have had offices in the California Building, are said to be making plans to erect a building exclusively for physicians. The reason for this action is said to be a proposed, unreasonable advance in rent.

GEORGIA.

Dr. John C. Goodman was elected city physician of Tifton, January 12, vice Dr. Arthur P. Hunter.

The Atlanta Board of Health reorganized January 18, re-elected Dr. William C. Jarmagin, chairman, and elected Dr. Everard H. Richardson, secretary.

The Macon Hospital, in 1900, cared for 232 white and 120 colored patients. The earnings from pay patients amounted to $3712.50, an increase of $1204 over those of the previous year.

The Savannah Hospital will benefit to the extent of about $40,000 by the will of the late Dr. William Duncan, of Savannah, on the death of the brother of the deceased. A bequest of $1500 is to be paid to the hospital at once.

ILLINOIS.

The isolation hospital at Peoria is ready and the three smallpox patients who have been quarantined pending its completion have been transferred to it. No new cases have developed.

Dr. Frank Anthony, Sterling, who served with distinction as major and surgeon of the 6th Illinois Infantry, U. S. V., in the war with Spain, has been appointed assistant surgeon-general of the Spanish-American War Veterans in the Department of Illinois, with the rank of colonel.

Chicago.

The donations to date toward the hospital for the treatment of consumptives to be erected this year at North Forty-eighth and North Avenues, under the management of the sisters of St. Elizabeth's Hospital, aggregate $20,067.

Norwegian Tabitha Hospital.—At its seventh annual meeting this institution reported assets of $37,640.75 and liabilities of $8037.27. A proposition to put the hospital under the management of one of the Norwegian church societies was rejected and it was decided to continue the management as heretofore, receiving patients irrespective of creed or nationality.

Alumni Organization.—Alumni of Bellevue Hospital Medical College and the medical department of New York University have organized a Western branch of the association, with Dr. James F. Todd, president; Drs. James G. Kiernan and John McKinlock, vice-presidents; Dr. Willis O. Nance, secretary, and Drs. Hugh T. Patrick, J. Sanderson Christison, Julius Grinker and Sanger Brown, executive committee.

The Health of the City.—The report of the Department of Health for the week ended January 26 shows a reduction of about 50 per cent. in the mortality from the acute pulmonary afflictions, as compared with the previous two weeks. The total mortality has also decreased more than 10 per cent. as compared with the previous three weeks. The rate per 1000 per annum was 14.77. The deaths under 1 year were 98, and over 60 years, 102. Consumption caused 53 deaths; pneumonia, 74; bronchitis, 26; influenza, 17, and violence, 30.

Internes in Asylums.—The Chicago Medical Society, Chicago Pathological Society, Chicago Neurological Society and Chicago Society for Internal Medicine have passed resolutions recommending the selection of at least four medical internes for each of the state hospitals for the insane; that such internes shall be selected by competitive examinations from the graduates of the medical colleges in the state, recognized by the State Board of Health, that they shall serve for one year, and receive as compensation lodging, board, washing, and $100 at the expiration of their term of service, and that the professors of nervous and mental diseases of the five medical colleges having the largest number of students in attendance shall be the examiners to select these internes.

Resolutions on Division of Fees.—The committee to whom was referred the resolutions of the Chicago Medical Society, January 23, met and adopted the following resolutions, which were recommended to the Society for adoption: "Resolved, That the offering, or the giving of a commission, or percentage of a fee, by a consulting physician or operating surgeon, or the asking or receiving such a fee or commission in any guise whatsoever, by the physician referring the case, is dishonest, disreputable and unethical, unless such arrangement be made with the full knowledge of the patient; Resolved, That a violation of this resolution shall subject the offender to expulsion from the Society."

The resolutions were adopted unanimously by a rising vote. The Physicians' Club has passed resolutions to the same effect: "Resolved, That the Physicians' Club of Chicago most severely condemns the seeking for or the receiving of a commission or part of a consultation or operation fee, as well as the offering or giving of a commission, or a part of a fee, as practices highly dishonorable and detrimental to the best interests of the medical profession."

Vaccination a Safeguard.—The interest in vaccination justifies belief that the city will be spared any such serious results from the present outbreak of smallpox as have usually followed epidemics, even when contagion was much less widely spread. The bulletin of the Health Department again refers to the object-lesson in vaccination that Germany furnishes the world. As has been truly said, that country stands alone in fulfilling in great measure the demands of hygiene as to smallpox. In consequence of the calamitous epidemic of 1870-71, it enacted the law of 1874, which makes vaccination obligatory in the first year of life and revaccination at the tenth year. In 1871, out of a population of 50,000,000, there were 143,000 deaths from smallpox. By vaccination and revaccination rigorously enforced through the law of 1874, this mortality has been reduced to 116 a year in a much larger population. These cases, moreover, occur almost exclusively in towns on the frontier. In a recent lecture, Dr. Bizzizziro, of Rome, said: "In 1870-71, during the Franco-German War, the two peoples interpenetrated each other, the German having its army completely revaccinated, while the French were vaccinated perfunctorily. Both were attacked by smallpox, but the French army numbered 23,000 deaths by it, while the German army had *only 278*; and in the same tent, breathing the same air, the French wounded were heavily visited by the disease, while the German wounded, having been revaccinated, had not a single case." No properly vaccinated person in Chicago need fear the present outbreak. Every unvaccinated person is in danger of the disease, besides being a menace to the reputation of the city. The type of the disease continues as mild as during the previous three years of its prevalence in the country, and its mortality-rate is insignificant. Of the two deaths that have occurred at the Isolation Hospital since last June, only one is properly attributable to smallpox. The other was the victim of a chronic incurable disease of the liver, and he was awaiting death at the U. S. Marine-Hospital when attacked by smallpox in a very mild form.

INDIANA.

The estate of the late Dr. Benjamin F. Swafford, of Terre Haute, is valued at $50,000.

Dr. William E. Stemen, who has been serving in the Philippine Islands as an acting assistant surgeon in the army, has returned, requested annulment of his contract, and will locate in Fort Wayne, associated with his father.

The president of the Indiana State Board of Health strongly favors the bill introduced in the present legislature providing for the establishment of a state laboratory. The last legislature passed a pure food law, but failed to appropriate funds for its enforcement.

A bill has been introduced in the house of representatives providing for the establishment by the state of a village for epileptics. A tract of not less than 1000 acres of land is to be purchased and $40,000 to be appropriated for this purpose. The bill goes into details, but does not suggest any particular site for the colony.

IOWA.

Dr. Harry M. Hoag sustained a loss of $1000 by the fire at Garner, January 11.

Dr. Harvey L. Cokenower, Clarinda, has been appointed chief division surgeon for the Keokuk & Western Railroad.

The formal transfer of the Iowa College of Physicians and Surgeons, Des Moines, to Drake University was made January 19.

Applicants numbering twenty-five assembled at Des Moines January 22 to take the examination of the Iowa State Board of Medical Examiners.

Dr. Levi Loar, of Selma, who was sentenced to the penitentiary for six months for attempted abortion, has appealed his case to the supreme court. He has also brought suit against an attorney and another person to recover $300, which he alleges he paid them to compromise the matter. He also claims $5000 damages.

District Physicians' Compensation.—In Iowa physicians are not burdened with heavy compensation for their services. The newly-elected physician for Red Oak city and township, including the jail, poor-house and hospital, medicines and services, receives $200 a year. Le Mars district pays its physician $175; Merrill district, $80; Remsen district, $65; Akron district, $100; Kingsley district, $75, and Buckingham and Perry townships, $57 per annum.

MICHIGAN.

Chippewa County Supervisors have appropriated $600 for the construction of a temporary isolation hospital on the poor-farm site.

Dr. W. H. Hutchings has been appointed chief surgeon of the Ann Arbor Railroad and Steamship Lines, with headquarters at Ann Arbor.

Bills have been introduced in the state senate and house of representatives, providing for the establishment of a hospital for consumptives.

Medical Men of the Soo have decided to form an association for mutual benefit and professional advancement. At the initial meeting held January 16, Dr. H. E. McLennan, Sault Ste. Marie, was elected secretary of the association.

Port Huron is to have a new hospital to be known as the "Memorial Hospital," to cost $25,000, and to be non-sectarian. Dr. Mortimer Wilson is the secretary of the association, which held its first meeting and adopted resolutions January 21.

MINNESOTA.

The coroner of St. Louis County, Dr. Samuel H. Boyer, of Duluth, has announced the appointment of medical deputies as follows: Dr. George N. Buchart, Hibbing, and Dr. George A. Tripp, Tower.

Dr. F. A. Dunsmoor, Minneapolis, medical director of the Asbury Hospital, suggests in his annual report that the old building be utilized as a pathological department, and that eventually it be maintained by the various hospitals of the city as a quarantine hospital, having separate wards for the different communicable diseases.

Smallpox Precautions.—To cope with smallpox in the logging camps of northern Wisconsin and Michigan, it was decided at a conference of health officers and loggers at Duluth, that vaccination should be encouraged, quarantine regulations enforced, and isolation hospitals provided. The loggers agreed to employ only vaccinated men or those immune by having had smallpox.

MISSOURI.

Dr. Harry H. Johnson, Neosho, has been appointed local surgeon for the Kansas City Southern Railway.

Dr. Oscar O. Braecklein, Kansas City, was fined $5 on January 19, for having failed to report a case of smallpox.

Dr. Budford M. Henry, Alba, was seriously injured in a runaway accident, January 12; his upper jaw was broken and his right eye so injured that it was necessary to have it enucleated.

The smallpox situation in Fayette was taken up at a recent meeting of the Howard County Board of Health, at Fayette, and it was decided to erect an isolation hospital at once, to place guards near homes where the disease is known to exist, and to order compulsory vaccination.

Missouri State Medical Association.—It is announced in the *Medical Herald* that the St. Louis and St. Joseph medical societies have passed resolutions urging the officers of the State Medical Association to change the date of the meeting from May 20-23 to February 26-28, and that immediate and active steps be taken to change the date and to promote the success of the session. The reason for this is that an important bill to regulate the practice of medicine is soon to be brought before the state legislature, and it is desired to give the association the opportunity to act in this matter in the interest of the profession at large.

NEW JERSEY.

Dr. Livingston Hinckley, Newark, for sixteen years superintendent of the Essex County Hospital for the Insane, has resigned.

The Orange Memorial Hospital, at the annual meeting of its directors, January 14, appointed Dr. William J. Chandler, South Orange, to fill the vacancy on the staff caused by the death of Dr. William Pierson, and Drs. Mefford Runyon, South Orange, and Harry E. Matthews, Orange, on the general staff.

Hospital for Consumptives.—Senator Hutchinson, of Mercer County, will introduce a bill asking for an appropriation of $50,000 for the establishment and equipment of a hospital for the care and treatment of cases of tuberculosis. The measure is the result of the action taken by the Trenton Board of Health on the protection against the spread of tuberculosis in healthy communities, and the bill was prepared and approved by the Mercer County Medical Society.

The Camden City Dispensary.—The board of managers of the dispensary have elected the following staff: Medical, Drs. John G. Doron, Grant E. Kirk, Levi B. Hirst, Frederick V. Dunn, Joseph H. Willis, William I. Kelchner, and William H. Pratt, Camden, Edgar B. Sharp, Berlin, Vernon E. De Grofft, Bridgeton; diseases of the eye, Dr. Robert Casperson, Camden; diseases of the nose, throat and ear, Drs. Ernest S. Ramsdell, Camden, and Vernon E. De Grofft, Bridgeton; district physicians, Drs. Joseph Willis and William H. Pratt, Camden.

Investigation of Morris Plains Hospital for the Insane.—A resolution has been introduced in the legislature calling for an investigation of this hospital. This action has been hastened on account of a case in which it was charged that the wife of a citizen had been committed to the asylum when her friends believed her to be sane. She has recently been adjudged in possession of her right mind and has been released. It is charged that sane persons have been committed to the hospital several times. A revision of the laws will also be asked for. It is hoped that some provision will be made for epileptics so that they may be kept separate from the chronic insane.

NEW YORK.

Dr. D. W. Harrington, Buffalo, has presented an ambulance to the Buffalo General Hospital.

Dr. H. McClellan, Jeffersonville, was arrested January 9, at the instance of the Sullivan County Medical Society, and held in bonds of $500 on the charge of practicing medicine without a state license.

Dr. Walter D. Greene, assistant health commissioner, of Buffalo, has notified each parochial school that every pupil not vaccinated within the last five years must be vaccinated before February 11.

The bill, affecting the State Board of Health, which provided for a commissioner at $2500, the appointment of two state officers to serve without pay, and for a secretary at a salary of $3500, has been drawn up and will be presented to the legislature at the present session.

The State Board of Health reports that with 150 cases of consumption and more than 40 of typhoid fever in Sing Sing prison, and with such defective plumbing arrangements that gases back up into the buildings with the rise of the tide, it does not appear that this prison is a fit abode for human beings other than those who have been sentenced to death.

Proposed Medical Law.—A bill has been introduced in the legislature having for its special object the suppression of quackery, and more particularly faith-curing and like humbugs. Opposition to this very proper measure has arisen from the proprietary medicine men, who fear that bringing into the category of those engaged in the practice of medicine, all persons who shall "prescribe, direct, recommend or advise for the use of any other person any remedy or agent whatsoever" will prevent them from advertising as hitherto, and this would end their business. Assemblyman Bell, who introduced the bill, declares, however, that it is not aimed at any class, trade or organized sect, and that it does not include patent medicines that are the recipes of registered physicians. He adds, as his opinion, that any one who practices medicine, be he a faith-healer, or what not, should first be educated as a physician.

NORTH DAKOTA.

Dr. August S. Eggers, Grand Forks, has returned from his European trip.

Dr. E. C. Branch has been appointed assistant physician of Cass county, succeeding Dr. Henry G. Fish, Wheatland.

The State Board of Medical Examiners met at Fargo, January 10, examined applicants and issued licenses to practice medicine to five physicians.

Dr. Henry A. Beaudoux, Fargo, has been appointed oculist and aurist of the divisions of the Northern Pacific Railway which end in Fargo. His territory extends from Mandan to St. Paul.

OHIO.

Dr. Alexander M. Steinfeld, house physician of the Children's Hospital, Columbus, has resigned.

Two Cincinnati irregulars were arrested at the instance of the State Board of Medical Examiners on the charge of practicing medicine without first having complied with the law requiring registration.

Dr. Benson E. Sager, Cleveland, has been arrested on the charge of failing to report a case of diphtheria within the legal limit. He claims that he took every precaution and his friends acknowledge his technical guilt.

Concentration of Medical Libraries.—A resolution has been introduced before the Cincinnati Library Board, looking toward the concentration of all the medical libraries in the city, namely, those medical works in the Public Library, the library of the City Hospital, and the books in the possession of the Academy of Medicine—a reading room at the Public Library, where they can be properly arranged and catalogued, and placed in charge of a competent attendant.

Board of Medical Registration and Examination.—The annual report of the Board, filed at Columbus, January 19, shows that, in 1900, 679 certificates were issued to graduates; 10 to practitioners of ten years' experience, and 6 on examination, while 30 applicants were rejected and two certificates revoked. Since the establishment of the Board, 9373 certificates have beeen issued to graduates, 725 to legal practitioners, 15 one-year certificates on examination, and 6 to graduates on examination. The rejections number 464, of which 215 were graduates, 227 legal practitioners and 22 as a result of examination.

Examination of Prostitutes.—During the past two months the health department of Cincinnati has been endeavoring to limit the spread of venereal diseases by forcing prostitutes to submit to rigid examination by some appointee of the Department. It had been learned that many of the physicians who had previously been engaged in this work were in the habit of issuing certificates without making any examination whatever. Suit was brought against the department in the person of the health officer, Dr. Clark W. Davis, by several physicians engaged in this business, for $10,000, under the plea that their work was unlawfully interfered with by the health department. At the regular meeting of the Cincinnati Academy of Medicine, January 21, a resolution was offered by Dr. Charles A. L. Reed, president of THE AMERICAN MEDICAL ASSOCIATION, seconded by Dr. Thadeus A. Reamy, and adopted, that the Academy approve and sanction the action of the Department and of Dr. Davis.

PENNSYLVANIA.

INFLUENZA PREVAILS to such an extent in Allentown that four schools have been closed. Many employees of the business houses are also ill with the disease.

DIPHTHERIA has recently increased in Mount Joy at an alarming rate. During the week ended January 21, seventeen new cases developed. Several deaths have occurred.

THE CONTRACT for the construction of a barracks, hospital and crematory at Marcus Hook has been awarded by the State Quarantine Board at a figure less than the amount available, $3500.

DISINFECTION AND FUMIGATION at Pittsburg have been discontinued because the sum appropriated for the purpose has been exhausted. Hereafter, unless further provision is made, disinfection must be made at the expense of the owners or occupants of buildings.

Philadelphia.

SNEAK THIEVES raided the offices of Drs. Otho D. Schaul and B. Frank Wentz, January 19.

A LAY BOARD OF TRUSTEES of the Medico-Chirurgical College and Hospital was elected January 15. Heretofore the trustees have been medical men.

THE BOARD OF CHARITIES AND CORRECTION at a recent meeting added thirteen members to the staff of the Philadelphia Hospital, making the total number 66.

DR. WILLIAM G. SPILLER has been appointed demonstrator in neuropathology at the University of Pennsylvania. He will conduct a two-months' elective course in this branch.

WILLIAM G. TOPLIS, chief of the bacteriological laboratory at the test filtration plant of the city's water-supply, has resigned, and William R. Copeland, of Pittsburg, has been appointed his successor at a salary of $200 a month.

DR. ANNA SHARPLESS has been re-elected president of the corporation of the West Philadelphia Hospital for Women. This institution has recently received $5000 for the endowment of a free bed, through the bequest of Mary Baker, deceased.

TENNESSEE.

DR. PIERRE WILSON, Denison, has gone to Baltimore, on his way to Germany, where he expects to study for nine months.

DR. JEFFERSON M. HARRISON, one of the oldest physicians in Knoxville, is very ill, and his recovery is considered doubtful.

DR. ANDREW P. NELSON, Winchester, has been elected physician, and Dr. Thomas B. Anderton, health officer, of Franklin County.

DR. JAMES M. INGE, Denton, has been appointed to the chair of anatomy and clinical surgery in the medical department of the University of Texas.

THE NEW CITY HOSPITAL at Knoxville was formally accepted by the city council, January 18. The cost of the building to date has been $32,243.36, and $15,000 additional is asked for to complete the buildings and grounds.

DR. J. B. ADAMS, San Antonio, who recently came to that city from Alabama, on account of his health, was seriously injured by a street-car, Jan. 14, sustaining crushing wounds of both legs, necessitating their amputation.

A CHARTER was granted January 12 to the Memphis Hospital Medical College Building Company, incorporated by Drs. William B. Rogers, Elmer E. Francis, James L. Minor, Bennett E. Henning, Alexander Erskine, Dudley D. Saunders, E. Paul Sale, B. Frank Turner and Thomas J. Crofford, with a capital stock of $40,000.

VIRGINIA.

DR. WILLIAM P. MATTHEWS has been chosen to succeed Dr. Lawrence Ingram as president of the Manchester Board of Health.

THE EXAMINATION held by the State Board of Medical Examiners, Dec. 17-20, resulted in the passing of 42 out of 53 applicants.

DR. HENRY T. BATTE, Norfolk, has been appointed city coroner of Norfolk, to succeed Dr. Robert S. Spillman, who has accepted a contract as acting assistant-surgeon in the army.

Faculty Changes.—The Medical College of Virginia has appointed Dr. Ennion G. Williams professor of pathology and bacteriology, vice Dr. Ernest C. Levy, resigned; and Dr. B. Lawrence Taliaferro, assistant to the chair; Dr. Greer Baughman, who has just returned after three years' study in Vienna, demonstrator of physiology, and Mr. E. D. Starke, prosector in anatomy. In the University College of Medicine, Dr. J. Allison Hodges has been chosen president to succeed the late Dr. Hunter McGuire and Dr. E. G. Hill, adjunct professor of chemistry.

GENERAL.

PASSED ASSISTANT SURGEON M. J. ROSENAU has returned to Washington, D. C., and resumed his duties as director of the hygienic laboratory of the U. S. Marine-Hospital Service. Dr. Rosenau has been doing special work in bacteriology at the Pasteur Institute, Paris, and the Pathological Institute, Vienna.

THE HOSPITAL-SHIP *Maine*, after thirteen months active service in South Africa, is to become a permanent addition to the British fleet. The vessel's complement of American surgeons, physicians and nurses, thirty-one in all, took formal leave of their ship at a reception tendered them at Portsmouth, England, January 16.

Journals Wanted.—Two copies of THE JOURNAL, vol. iii, No. ii, are wanted to complete sets for libraries, and we will pay 25 cents each for the return of issues of the above date to THE JOURNAL OF THE A. M. A., 61 Market Street, Chicago.

Cats and Plague Infection.—A representative of the U. S. Marine-Hospital Service at Constantinople, under date of Dec. 29, 1900, citing a case of bubonic plague which occurred in the person of the captain of the steamship *Dundee*, which plies between Egypt and Syria, states that the captain had six cats aboard, of which he was very fond. Several dead rats were found on the vessel, and shortly after this three of the cats died. The captain was then taken ill with bubonic plague and died.

Smallpox Data.—In view of the fact of the extraordinary prevalence of smallpox throughout the United States, it now being epidemic in greater or less severity in nearly every state and territory of the Union, the Surgeon-General of the U. S. Marine-Hospital Service is sending out the publications of the Service on the diagnosis, prevention, and management of this disease, to the health authorities of every town in which he learns there has been a case of smallpox.

San Francisco Plague Reports.—*Case 23:* Chun Way Lung, a male Mongolian, aged 60, a merchant, born in China, but residing at 720 Jackson St., San Francisco, died January 6. Dr. Kellogg, the city bacteriologist, saw the case on the afternoon of the 7th, with Dr. Wilson. He was a large, well built and rather fat man, showing no signs of continued illness. His associate gave a history of illness from gonorrhea for twenty days, a swelling appearing about a week before death. They also said he had been very feverish and thirsty, drinking water all the time, and that he had vomited several times during the last two or three days.

Examination showed a large flat swelling in the left groin, over Poupart's ligament, and extending internally to the middle line over the symphysis. Incision of this swelling did not disclose any lymph nodes, but there was much edema, and the tissues were dark, hemorrhagic and necrotic. A piece of the tissue removed showed the presence of the bacillus pestis in large numbers.

An autopsy was held the next morning by Dr. Kellogg, those present being Dr. White, of the U. S. Marine-Hospital Service, and Drs. Kinyoun, Morton, Ryfkogel and Wilson. The lungs were found to be normal, the heart very flabby and containing dark fluid blood, and about one ounce of dark bloody serum in the pericardium. The peritoneum was dry. The spleen was somewhat enlarged, its substance very dark, soft and pultaceous. Smears from the spleen showed many typical plague bacilli.

Two guinea-pigs inoculated with spleen from the case both died in five days of typical plague infection, and the organism has been recovered in pure culture from their organs and blood.

Case 24.—Leam Wing Low, aged 59, a male Mongolian, a laborer, was born in China and has been thirteen years in California, his residence 833 Clay St. He died January 15, at

6 a.m. Dr. Kellogg saw the case on the same day, with Dr. Wilson, and removed a portion of gland from a bubo in the right groin, just below Poupart's ligament. Microscopically the specimen showed the presence of the plague bacillus. He removed the spleen the next morning and found it to be much enlarged, the capsule tense, the substance soft, very dark, and the trabeculæ obliterated. The blood-vessels of the peritoneum covering the intestines were injected. No other glands were enlarged. Smears from the spleen showed the plague bacillus in small numbers. Inoculation experiments have been commenced.

Case 25.—Angelo Colombo, a native of Switzerland, residing at 5 Lafayette Place, was brought into the City and County Hospital by the police patrol on January 14 in an unconscious condition. The following is from the hospital record: "January 15. Patient well developed, well nourished, face flushed and cyanotic. Lies apathetic, pupils moderate in size, equal, and react to the light. Patient lies with mouth open. Tongue and lips dry. Vessels of neck pulsate. No dulness over lungs. Thorax well formed. Heart sounds clear. Abdomen not distended or sensitive. Liver extends 15 cm. below the margin of the ribs. Spleen reaches posterior axillary line. Patient is able to move both upper and lower extremities. Is continually restless and picking at the bed clothes. Temperature when admitted was 97.4. Bladder distended, passed per catheter 760 c.c. urine, acid, sp. gr. 1019, no sugar, a trace of albumin. Was given 1 m. ol. tiglii. Died Jan. 15th, 11 p.m." Dr. Kellogg saw the patient at the city morgue. He found the spleen much enlarged, rather soft, the capsule wrinkled, and having several spots of opaque white thickenings of the latter. The cut surface was dark purple, the trabeculæ partially obliterated. The entire extent of the peritoneum was covered with a hemorrhagic sticky fibrinous exudate, matting together the omentum, intestines and parietal layer of peritoneum. There was no fluid in the peritoneum, and no enlargement of the lymph glands. Smears from the spleen showed the presence of a bipolar staining bacillus which was morphologically the bacillus of plague. Inoculation experiments have been commenced.

CANADA.

A BANQUET was tendered the staff of the *Canadian Journal of Medicine and Surgery*, Toronto, recently.

IN WINNIPEG, a man was recently found guilty of practicing medicine without being duly qualified by the medical act of Manitoba, under two different charges, and fined $25 and costs on each charge.

Scarlet Fever Epidemic.—From a table compiled by the Montreal Health Department, it is evident that that city has passed through a serious epidemic of scarlet fever. The cases in the Civic Hospital, from Sept. 29, 1900, to Jan. 19, 1901, numbered 681. The deaths for the same period were 139, the death-rate being 20.23 per cent.

Druggists and Medical Practice.—The medical detective of the Ontario Medical Council has filed information against eight Toronto druggists for practicing medicine without a license. The cases will be up in the police court next week, and will be watched with interest. It is stated that there is considerable of this sort of work done in Toronto.

La Grippe Mortality.—In Toronto, sixty deaths occurred from acute pulmonary diseases alone between Jan. 1 and 25. The total number of deaths there, to the 25th, was 278, and during the whole of January, 1900, the number was 265. In 1900 the deaths from pulmonary causes numbered 23 for the month, those from diphtheria 10, while this year the latter reached 16 to January 25.

Changes in Ontario Asylums.—Dr. Wilson, assistant at the Brockville Asylum, has been transferred to London, to take the place of Dr. A. T. Hobbs, who has resigned to enter on private practice. Dr. Laidlaw, assistant at the Orillia Asylum, who has just returned from South Africa, has been promoted to the vacancy at Brockville; while Dr. St. Charles, also of Orillia, has been transferred to Hamilton, to succeed Dr. Herriman, who has been transferred to the Kingston institution. The changes took effect Feb. 1.

Scholarship in Medicine.—Queen's Medical Faculty has decided to found a scholarship in medicine in commemoration of Dr. Fife Fowler, dean of the faculty, who has given forty-six years of active service to the college. The scholarship will be known as the Dean Fowler scholarship; $10,000 is required, and the graduates of Queen's throughout Canada and the United States will be asked to contribute. The faculty has already subscribed a goodly portion of this amount. In addition, $10,000 is to be expended on improving and enlarging the medical building. This amount will be raised from members of the faculty.

Deaf, Dumb and Blind.—The annual reports on the Ontario institutions for the education of deaf and dumb at Belleville, and of the blind at Brantford, have just been published. At the Belleville institution, 152 males and 130 females have been in attendance through the year which ended Sept. 30, 1900. Since its establishment, thirty years ago, 1187 children have been treated there. At the institute for the blind, at Brantford, 61 males and 52 females were in attendance last year, this being slightly less than the previous year. It is considered that the blind are decreasing in this province.

Consumptives and Tent Life.—During the recent cold snap, when the thermometer must have registered somewhere in the neighborhood of 20 degrees below zero, many of the consumptives at the sanatorium at Gravenhurst lived and slept in tents, without inconvenience, and, it is stated, with positive enjoyment and advantage to their physical well-being. Dr. J. H. Elliott, formerly superintendent, has returned to the institution after an absence of two years in foreign lands. Most of his time abroad has been devoted to the study of laboratory methods in connection with the bacteriology of tuberculosis, as well as visiting establishments for the treatment of this disease. He was one of the expedition from the Tropical School of Medicine at Liverpool, organized for investigating the phenomena of malaria on the west coast of Africa.

FOREIGN.

THE BUST of the Brussels otologist, C. Delstanche, was unveiled Sunday, January 20, in the otologic clinic of which he was the founder.

THE KATHARINE HOSPITAL at Moscow, the one connected with the clinics of the university, recently celebrated the 125th anniversary of its foundation.

LISBON, PORTUGAL, in addition to more than 20 practicing physicians is said to boast of 150 medical practitioners without legal qualifications—quacks.

DR. JAMES GRAHAM, Sidney, N. S. W., has been elected mayor, and it is expected that the civic hygiene will now be of the best, decreasing the probability of any further plague outbreaks.

ACCORDING TO the *Presse Médicale* of Paris, the budget for the hospitals in 1901 includes an appropriation of 718,000 francs or about $143,000 for gauze alone. This corresponds to 6,300,000 meters.

THE RUSSIAN government has authorized the foundation of a university for women, to have only faculties of medicine, pure science and natural science. A merchant of Moscow has given 3,000,000 roubles for its establishment.

THE MEDICAL SOCIETY OF ATHENS is organizing a "Pan-Hellenic Congress of Medicine" to take place in Athens next May. Foreigners will be welcomed as members of the Congress. The address of the secretary is M. Mangakis, 85, rue de l'Université, Athens.

PLAGUE REPORTS from Sidney, N. S. W., dated December 29, state that there are no further cases in the colony and that on December 3 there were but two under treatment at Brisbane. During the week ending December 3, three cases were reported at Thursday Island.

IN THE GERMAN town of Biebrich, a charlatan treated a pregnant girl for ascites, and, when she was delivered, allowed the child to die, from ignorance of the proper procedures. Criminal proceedings were instituted against him and he was condemned to two months in prison.

HUCHARD'S CLINICAL amphitheater at the Necker Hospital in Paris has been remodelled at his expense, and he has inaugurated a series of bedside talks on therapeutics. If a listener fails to understand anything that has been said, he is to ask for further explanations, placing his request in a box provided therefor, and the next day Huchard again refers to the matter.

Seats for Employes.—The *Sem. Méd.* says that the French law, which went into operation with the new year, decrees that seats corresponding to the number of female employes must be provided in stores. The German law requires "a sufficient number of seats" and the English law of 1899 one seat for each three female employes.

Mecca Pilgrimages Regulated.—The pilgrimages to Mecca are to be strictly supervised this year by the sanitary authorities, and they are to be restricted as much as possible. Several districts of India, including the Bombay Presidency, have forbidden residents from taking part in the pilgrimage. All pilgrims leaving India must sail from two appointed ports and submit to rigid disinfection.

G. A. Chatin, M.D.—The death of G. A. Chatin, M.D., of Paris, is announced. He was born in 1813, a member of the Académie de Médecine for forty-eight years, and at one time its president. He was director of the Ecole de Pharmacie and author of the "Comparative Anatomy of Vegetables," among other works. . . . Professor Dubreuil, of Montpellier, France, after twenty years of gratuitous labors in the hospitals, has left to them his property of $140,000. He was 66 years of age at the time of his death.

Inoculations with Syphilis.—Neisser's inoculation of three prostitutes with syphilitic serum some years ago has been frequently mentioned in these columns. He has finally been officially condemned by the German disciplinary court, which has been investigating the matter, and besides a reprimand, a fine of about $75 has been imposed. The minister of public instruction at once issued a proclamation forbidding, in all clinics and other institutions for the care of the sick, all medical intervention other than for diagnostic, curative or preventive purposes.

German Medical Courses.—It is now a definitely established fact that graduates of the technical high schools in Germany are eligible to admission to the medical course in the universities, the same as those who have taken the classical course. An editorial in the *Allg. Med. C. Ztg.* observes that some persons attribute to the unpractical, classical training of physicians in the past the apparent contempt for worldly goods which induces certain members of the profession to serve the sickness-insurance societies at terms lower than the cheapest day laborer's hire. If it is the classical training which is responsible for this ultra-magnanimous conduct, then the acquisition of technically trained members will prove a boon to the profession. But there is little chance that the coolly practical, technical graduates will turn their attention to the arduous career of medicine.

Medical Practice in New South Wales.—The new medical practice act for New South Wales calls for a term of five years' study of medicine. This would, therefore, exclude an American from practice because he is supposed to have graduated from a school of but four years. However, it seems that the first of the five years is similar to the last year usually spent in an American preparatory school before entering an American medical college, and the regulations of the British Medical Council says: "Graduates in the arts and sciences of any university recognized by the medical council, who shall have spent a year in the study of physics, chemistry and biology, and have passed an examination in these studies for the degrees in question, shall be held to have completed the first of the five years of medical study."

Red Cross Society of Japan.—From the *Times* (London) of January 7, we learn that the Red Cross Society of Japan is a very flourishing institution. Its list of subscribers contains nearly 700,000 names, and its annual income is 2,000,000 yen. It has hospitals in the chief cities, that in Tokio being especially fine, and it possesses a large staff of trained nurses, male and female, who in times of peace are at the service of the general public. The Japanese woman makes an admirable nurse. She has been criticised by some foreigners for lack of resolute initiative, and the criticism is probably just where there is a question of dealing with the "masterful Occidental." But she shows no want of resolution in the presence of patients of her own nationality, and her gentleness, sympathy, unremitting attention and complete self-effacement are beautiful qualities. One of the interesting and novel features of the society's organization is that it has two large steamers—the *Mercy* (Hakuai) and the *Saviour* (Kosai)—which are specially constructed and equipped as floating hospitals. In these ships the wounded and the sick find all the comforts furnished by a first-class hospital on shore, and are under the care of a large staff of highly-trained surgeons and nurses. The arrangement made at Tien-tsin was that all the light cases should be conveyed by the most suitable vessels in the transport fleet, and that the graver should be carried by the Red Cross ships. The *Mercy* and the *Saviour* each made five voyages from Ta-ku to Hiroshima between July 18 and October 11, and carried altogether 1678 patients, wounded and sick. Eleven ordinary steamers were similarly employed, and, according to returns just published, the total number of wounded officers and men carried to Hiroshima from the beginning of the complication until October 31 was 776, and the number of sick 2643, making an aggregate of 3419. Out of these the recoveries thus far have been 1717, and the deaths 110. The Red Cross Society has disbursed a sum of 600,000 yen, but the government's outlays are not yet publicly known.

Dividing the Fee.

Montpelier, Ind., Jan. 25, 1901.

To the Editor:—The *Chicago Times-Herald*, in its issue of yesterday, contained an article on "The Doctors at Odds on Divided Fees." This appeals so strongly to a common sense of justice that I wish to take sides with those physicians who are opposed to the fee dividing scheme, and endorse as emphatically as I can their reasons for not wanting to reduce the profession to a commercial basis.

Some time ago I received a circular letter, and you may well imagine my disgust and chagrin when I read it. It evidently had emanated from one who fully understood the financial side of the "fee dividing" problem. This would-be surgeon—I say would-be, as no reputable one would send out such a communication—with a great wealth of rhetorical diction, intimated the injustice of not dividing the fee with the man who had brains enough to diagnose the case, and intimated his intention of doing so with all who would send their cases to him for surgical aid. This, to me, had an unmistakable flavor of "fee faw fum."

It has been, during my short career as a general practitioner, my pleasure to consult surgeons, and retain them to operate. I have stood by and eagerly watched each step, while the benefit I derived from this privilege was compensation far in excess of the division of any fee.

Is it possible to conceive of a future time when general practitioners will turn their patients for operation to the highest surgical bidder? I hope not. May a time come when surgeons will clamor with their bidding for an operation, like a pack of wolves howling and snarling over a corpse? I am sure not. Will a time come when the wheels of professional ambition will be retarded or clogged by the having to "divide the fee" proposition staring one in the face who is trudging up the rugged steep, bearing that inevitable banner of excelsior? I pray not. Yet I feel that such a move as dividing fees would be the nucleus from which would grow professional disgrace and ruin.

On the evening of November 3, 1900, the profession of the country set the seal of its approval on hard work and earnest study by tendering to Dr. Christian Fenger a testimonial banquet (see The Journal, vol. xxxv, p. 1214). This great surgeon, by incessant toil, has won the everlasting praise of his fellows and set an example we may do well to follow, but do not say to him, You may operate on my case if you "divide the fee."

J. C. O'Day, M.D.

Intravenous Transfusion of Formaldehyde Solutions.

Park City, Utah, Jan. 26, 1901.

To the Editor:—In your editorial, Dec. 29, 1900, on "Treatment of Tuberculosis," you remark that Dr. R. McGuire has lately treated tuberculosis by intravascular injections of formaldehyde solutions.

Permit me to report some experiments I made three years ago on dogs with intravenous injections of solutions of formaldehyde. Lack of time and a laboratory forced me to give up my studies in this line. I tried to solve the two following propositions: 1. Would it be possible, without injuring the animal, to introduce into the circulation formaldehyde in sufficient amount to disinfect tuberculous lungs? 2. By introducing formaldehyde into a vein of the foreleg—forearm—would the gas, after permeating the lungs, escape by the mouth, or would it go to the left side of the heart and into the general circulation?

It has been proved that plain, sterile water, transfused into the blood-vessels, will injure the blood-corpuscles; therefore, normal salt solution, which is compatible with formaldehyde, was chosen as the menstruum for the formaldehyde. It has, also, been proven that gases can be introduced into the blood without stopping the action of the heart. A piece of white blotting paper was saturated with a solution of fuchsin, then discolorized with dilute hydrochloric acid, which turns it yellow; when formaldehyde gas strikes this paper, the yellow color turns violet. I mixed 112 minims of formalin—45 minims of pure formaldehyde—with 2 ounces of warm normal salt solution; a vein was picked up in a dog's foreleg and the solution was slowly transfused; the yellow-colored blotting paper was immediately held near the dog's mouth; the violet color appeared in a few seconds. Of course, the dog died in two or three minutes, but the second proposition was solved—the gas escaped by the mouth. On the second dog, I used 25 minims formalin—10 minims pure formaldehyde. On a third dog, I used 37 minims formalin—15 minims pure formaldehyde. These two dogs lived and seemed as well after the experiments as before. In these, also, the formaldehyde escaped by the mouth. The yellow colored blotting paper gave no reaction of the formaldehyde test when arterial blood from the dead dog was heated. E. Viko, M.D.

The Philadelphia Medical Journal.

Philadelphia, Jan. 22, 1901.

To the Editor:—The issue of The Journal for January 5 contained statements which might convey a wrong impression concerning the changes recently made in the *Philadelphia Medical Journal*, its financial strength, the chances of its continued success and the nature of its aims as an exponent of high professional ethics. The insertion of this letter in your columns would therefore be greatly appreciated.

The changes recently made in the editorial department were based upon the action of a board of trustees, which contained at the time, as it does now, a proportion of five physicians to every lay member. That the *Journal* has, and will continue to be inspired by men who are familiar with "high ideals in medicine" and the needs of the general profession is therefore evident. True, the shareholders have not as yet received dividends. This is due to the fact that they have "sunk a large amount of money" in the elaboration of a foundation as enduring as the original plan of the *Philadelphia Medical Journal* was comprehensive. This was not done through the "lack of sagacity of those who put their money into it," but in order to better serve its subscribers and merit their continued patronage—the secret of success. Indeed, never has the ethical, scientific and financial position of the *Philadelphia Medical Journal* been more secure than at the present time; and, far from having "a demoralizing effect on legitimate medical journalism," it will continue, with its old contemporaries, especially The Journal of the American Medical Association, in its efforts to maintain the dignity, honor and scientific standard of American medicine. Your truly,

John B. Roberts, M.D., Secretary.

By Order of the Board of Trustees.

The Association's 1902 Meeting.

Memphis, Tenn., Jan. 22, 1901.

To the Editor:—The 1902 meeting of the American Medical Association should logically come south. Other southern cities, Atlanta, New Orleans, Louisville and Nashville have been honored, and Memphis is now the third largest city south of the Ohio River, with a population, by the U. S. census of 1900, of 102,320. It is well and centrally located, being in the very heart of the great Mississippi Valley. We have also eleven trunk lines, making Memphis accessible from all points. Besides, the adjacent territory, Mississippi, Alabama, Arkansas, Tennessee, Louisiana, Texas and southeast Missouri has many good physicians who have never joined the American Medical Association. I believe that if Memphis could secure the meeting next year our membership would be materially increased. Some few have doubted our ability to entertain the Association, but we now have in course of construction one of the finest hotels in the South, and our hotel facilities in general will be ample to accommodate all who may be present. With reference to suitable halls for the various sections, I can safely say there will be no trouble in securing all we need. We have a large auditorium, with a seating capacity of 4500, which would serve well for the general sessions, also for exhibits, and May would be the ideal month for the meeting should it come south. Our business men are liberal and progressive and it is safe to say that the Merchants' Exchange will do its part. Let the American Medical Association come south in 1902, to Memphis, the Queen City of the Mississippi Valley. Respectfully, Frank A. Jones, M.D.

Incised Wounds.

Chicago, Jan. 28, 1901.

To the Editor:—In regard to abstract No. 121, in the January 19 issue of The Journal (p. 216) I wish to say, without criticizing the author, that I have been using that method ever since it was shown me by Dr. J. A. McDonell, of this city, and it was not original with him. As early as July, 1872, while Dr. McDonell was practicing in Boston, N. Y., an old shoemaker, named Silas Root, witnessed the Doctor trying to sew up an incised wound in a child, and as the child cried from pain this old shoemaker said: "Let me show how to coapt those edges without causing the child any pain." He thereupon took two pieces of shoeleather, shaved the rough parts off, punched holes in the approximating edges and then, by means of shoemaker's wax, attached these two pieces of leather to the skin on each side of the wound, and then laced them together with ordinary fine twine. Union was complete, and Dr. McDonell was so pleased with the result that this method became routine with him in all incised wounds. Later when adhesive plaster was put on the market, Dr. McDonell began to use that, approximating the free edges with a sterilized needle and linen thread, and this is now his routine and has been since the introduction of adhesive plaster.

The British Pharmacopeia.

Ashton, R. I., Jan. 21, 1901.

To the Editor:—In The Journal of January 19, your London correspondent speaking of the British Pharmacopeia states that there were converted into this three pharmacopeias in the United Kingdom, issued by the Colleges of Physicians of London, Edinburgh and Glasgow respectively.

Now, in a great organ of professional thought and action like The Journal its readers expect above all things accuracy. There are, undoubtedly, in the United Kingdom three colleges of physicians, one for each kingdom, in London, Edinburgh and Dublin.

Your correspondent robs Ireland, giving Scotland double her due. N. O'D. Parks, L. C. P. I.

Marriages.

W. H. Ramsey, M.D., Omaha, Neb., to Miss Edna Ball, Waco, Texas, January 16.

Edward B. Evans, M.D., Fargo, N. Dak., to Miss Jennie Lind Lewis, January 13.

Nelson M. Black, M.D., to Miss Erna Leidersdorf, both of Milwaukee, Wis., January 22.

Frank E. Donelan, M.D., Glenwood, Iowa, to Miss Winifred Wells, Tabor, Iowa, January 13.

Charles R. Grandy, M.D., Norfolk, Va., to Miss Mabel Dickman, Richmond, Va., January 17.

Jediah H. Clark, M.D., Richmond, Ind., to Miss Anna Hessler, Connersville, Ind., January 1.

Andrew Ekern, M.D., Grand Forks, N. Dak., to Miss Signa Hustmark, Seattle, Wash., January 16.

Frank Millard Severson, M.D., Seneca Falls, N. Y., to Miss Anna Evelyn Mead, Chicago, January 16.

Deaths and Obituaries.

William D. Haggard, Sr., died at Columbia, Tenn., January 25, from the effects of a stroke of paralysis which occurred the previous day. He was born in Kentucky, 74 years ago, and his ambition from boyhood was to be a physician.

When he was 11 years old, his father died, and, as the oldest child, he assisted his mother in the management of the plantation. Later he was a clerk in a store, a school teacher, and at the age of 19 became tax assessor of Marion County. He saved enough to begin his medical studies at the University of Louisville in 1847, but completed his medical course at Jefferson Medical College, Philadelphia, and was graduated there in 1851. He practiced in Gallatin, Tenn., until 1864, and then moved to his farm near Sharon Hill. In 1874 he moved to Nashville, and was connected, as an instructor, with the medical department of the University of Nashville and Vanderbilt University. In 1884, he was elected to the chair of diseases of women and children in the medical department of the University of Tennessee, which chair he had occupied until recently, when he resigned in favor of his son. He has been a continuous member of the Tennessee Medical Society for a half century, and of The American Medical Association for many years. In 1887 he served as chairman of the Section on the Diseases of Children. In 1889 he was instrumental in organizing the Southern Surgical and Gynecological Association. In 1892 he was elected president of the Nashville Academy of Medicine, and in 1893 one of the honorary presidents of the Pan-American Medical Congress. He had been a faithful and unusually active and successful practitioner of medicine, and during the last ten or fifteen years has devoted most of his attention to surgery, in which he gained fame throughout the South. He also found time to devote to the teaching of his profession to thousands of students throughout the entire West and South, who will mourn his loss and revere his memory.

Hiram Christopher, M.D., University of Louisville, Ky., 1847, of St. Joseph, Mo., died January 21, after a long illness, aged 81. He was known as a scholar, and as an enthusiastic student of languages, and especially well versed in Greek. For a number of years he was dean of the Ensworth Medical College and he was at the time of his death, senior editor of the *Medical Herald*. At a meeting of the St. Joseph Medical Society, January 23, resolutions were adopted expressing the heartfelt sympathy and sorrow of the society at Dr. Christopher's death, and, as a mark of respect to his memory, the society adjourned.

George Lester Rundle, M.D., New York University, 1890, was injured by a train at Delawanna, N. J., January 20, and died the next day at the Passaic, N. J., Hospital. He was a member of The American Medical Association and surgeon of the Passaic General Hospital, as well as a member of the Passaic district and city societies.

David Caldwell Ireland, M.D., University of Pennsylvania, 1861, died suddenly of heart failure consequent on la grippe, at his home in Baltimore, Md., aged 57. He had served as member of the city council, coroner and president of the pension examining board.

William E. Davis, M.D., Meharry Medical College, Nashville, Tenn., 1887, a colored physician of Fort Worth, Texas, and a member of The American Medical Association, died at his home in Fort Worth, January 1, from pneumonia. He was 39 years old.

E. P. Ross, M.D., Manitoba Medical College, Winnipeg, 1900, who had recently returned from South Africa, invalided on account of enteric fever, died suddenly from la grippe, January 14, aged 28. He was house surgeon at St. Boniface Hospital, Winnipeg.

William S. Smith, M.D., University of Minnesota, 1892, of St. Clair, Minn., a member of The American Medical Association, died from complications following an operation for acute appendicitis, at Rochester, Minn., January 18, aged 31.

Edward Pinckney Becton, M.D., University of Tennessee, 1857, superintendent of the Texas State Asylum for the Blind and surgeon of the Twenty-second Texas Infantry C. S. A., died at Austin, January 14, from la grippe, at the age of 66.

Henry W. Leonard, M.D., Miami Medical College, Cincinnati, Ohio, staff surgeon of the Fifty-first New York Infantry, and for many years in practice at Camden, N. Y., died in New York City, January 14, after a long illness, aged 71.

Luther Newcomb, M.D., University of Vermont, 1885, and for thirteen years thereafter in practice in Lynn, Mass., died after a lingering illness, from Bright's disease, at his home in Montpelier, Vt., January 10, aged 39.

William H. Parkhurst, M.D., Western College of Physicians and Surgeons, Fairfield, N. Y., 1841, one of the oldest physicians in the Mohawk Valley, died at his home in Frankfort, N. Y., January 22, aged 88 years.

Joseph C. Hatheway, M.D., Jefferson Medical College, Philadelphia, 1856, one of the oldest practicing physicians in Ottawa, Ill., died at his home in that city after an illness of six weeks, January 21, aged 67.

Abraham Bettman, M.D., an old resident of Cincinnati, Ohio, and before his retirement, one of the leading physicians 1852 died at his home near Fisherville, Va., January 16, after a long illness, aged 95.

Stephen J. Reynolds, M.D., New York University, 1851. one of the oldest physicians of eastern Missouri, died at his home in Bowling Green, from acute nephritis, January 20, aged 76.

Samuel J. Coyne, M.D., University of Cincinnati, 1879, formerly a practitioner of Aberdeen, S.D., died from an overdose of medicine, January 21, at his home, opposite Dayton, Minn., aged 56.

James Watson, M.D., New York University, 1872, died January 23, at his home in Belleville, N. Y., suddenly, from heart failure as a sequel of la grippe. He was 67 years of age.

Walter Butterbaugh, M.D., State University of Iowa, 1897, died at Denver, Colo., December 25, from tuberculosis contracted while in practice in Riverside, Iowa. He was 31 years old.

Alexander C. Reid, M.D., University of Aberdeen, Scotland, 1865, a retired physician of Hamilton, Ont., died at his home in that city, from paralysis, January 18, aged 63.

William J. Harris, M.D., Rush Medical College, 1866, a member of The American Medical Association, died at his home, near Beatrice, Neb., January 26, aged 80.

Gottleib Miller, M.D., College of Physicians and Surgeons, Keokuk, Iowa, 1882, a specialist on the eye and ear, died at his home in Ottawa, Ill., January 12, aged 76.

James Boyd McKelvy, M.D., University of Pennsylvania, 1848, was killed by a fall from a window, at his home in Bloomsburg, Pa., January 14, aged 70.

N. M. Bonham, M.D., Missouri Medical College, St. Louis, 1860, a pioneer physician and preacher of Missouri, died at New Franklin, Mo., January 18.

Henry Cotton, M.D., University of Minnesota, 1894, died at St. Barnabas Hospital, Minneapolis, from typhoid fever, January 22, at the age of 33.

Burt Andrews, M.D., Bellevue Hospital Medical College, 1891, died at his home in Augusta, Me., from tuberculosis, January 12, aged 32.

John A. Gilbert, M.D., University of Wooster, 1872, of Cleveland, Ohio, died January 22, after a prolonged illness from spinal disease.

Stephen M. Bayard, M.D., died at his home in Ionia, Mich., January 17, from pneumonia, after an illness of ten days. His age was 81 years.

George A. Landers, M.D., University of Cincinnati, 1883, of Van Buren, Ind., died from paralysis, at Fortville, Ohio, January 18, aged 42.

William F. Cook, M.D., Medical College of Ohio, Cincinnati, 1897, died from pneumonia, at his home in Latonia, Ky., January 17.

Albert L. Wagner, M.D., College of Physicians and Surgeons, Chicago, 1885, recently died suddenly at his home in Lapaz, Ind.

George E. Fullerton, M.D., University of Michigan, a retired physician of Marion, Iowa, died recently at his home in that city.

W. Frank Ross, M.D., Barnes Medical College, St. Louis, 1895, died at his home in Champaign, Ill., January 23, aged 44.

Lucius J. W. Lee, M.D., University of Pennsylvania, from pneumonia, at his home in Brooklyn, N. Y., January 8, aged 64 yellow; when formaldehyde gas strikes this paper, the yellow color turns violet. I mixed 112 minims of formalin—45 minims of pure formaldehyde—with 2 ounces of warm normal salt solution; a vein was picked up in a dog's foreleg and the solution was slowly transfused; the yellow-colored blotting paper was immediately held near the dog's mouth; the violet color appeared in a few seconds. Of course, the dog died in two or three minutes, but the second proposition was solved—the gas escaped by the mouth. On the second dog, I used 25 minims formalin—10 minims pure formaldehyde. On a third dog, I used 37 minims formalin—15 minims pure formaldehyde. These two dogs lived and seemed as well after the experiments as before. In these, also, the formaldehyde escaped by the mouth. The yellow colored blotting paper gave no reaction of the formaldehyde test when arterial blood from the dead dog was heated. E. Viko, M.D.

George Lester Rundle, M.D., New York University, 1890, was injured by a train at Delawanna, N. J., January 20, and died the next day at the Passaic, N. J., Hospital. He was a member of The American Medical Association and surgeon of the Passaic General Hospital, as well as a member of the Passaic district and city societies.

David Caldwell Ireland, M.D., University of Pennsylvania, 1861, died suddenly of heart failure consequent on la grippe, at his home in Baltimore, Md., aged 57. He had served as member of the city council, coroner and president of the pension examining board.

William E. Davis, M.D., Meharry Medical College, Nashville, Tenn., 1887, a colored physician of Fort Worth, Texas, and a member of The American Medical Association, died at his home in Fort Worth, January 1, from pneumonia. He was 39 years old.

E. P. Ross, M.D., Manitoba Medical College, Winnipeg, 1900, who had recently returned from South Africa, invalided on account of enteric fever, died suddenly from la grippe, January 14, aged 28. He was house surgeon at St. Boniface Hospital, Winnipeg.

William S. Smith, M.D., University of Minnesota, 1892, of St. Clair, Minn., a member of The American Medical Association, died from complications following an operation for acute appendicitis, at Rochester, Minn., January 18, aged 31.

Edward Pinckney Becton, M.D., University of Tennessee, 1857, superintendent of the Texas State Asylum for the Blind and surgeon of the Twenty-second Texas Infantry C. S. A., died at Austin, January 14, from la grippe, at the age of 66.

Henry W. Leonard, M.D., Miami Medical College, Cincinnati, Ohio, staff surgeon of the Fifty-first New York Infantry, and for many years in practice at Camden, N. Y., died in New York City, January 14, after a long illness, aged 71.

Luther Newcomb, M.D., University of Vermont, 1885, and for thirteen years thereafter in practice in Lynn, Mass., died after a lingering illness, from Bright's disease, at his home in Montpelier, Vt., January 10, aged 39.

William H. Parkhurst, M.D., Western College of Physicians and Surgeons, Fairfield, N. Y., 1841, one of the oldest physicians in the Mohawk Valley, died at his home in Frankfort, N. Y., January 22, aged 88 years.

Joseph C. Hatheway, M.D., Jefferson Medical College, Philadelphia, 1856, one of the oldest practicing physicians in Ottawa, Ill., died at his home in that city after an illness of six weeks, January 21, aged 67.

Abraham Bettman, M.D., an old resident of Cincinnati, Ohio, and before his retirement, one of the leading physicians 1852 died at his home near Fisherville, Va., January 16, after a long illness, aged 95.

Stephen J. Reynolds, M.D., New York University, 1851, one of the oldest physicians of eastern Missouri, died at his home in Bowling Green, from acute nephritis, January 20, aged 76.

Samuel J. Coyne, M.D., University of Cincinnati, 1879, formerly a practitioner of Aberdeen, S.D., died from an overdose of medicine, January 21, at his home, opposite Dayton, Minn., aged 56.

James Watson, M.D., New York University, 1872, died January 23, at his home in Belleville, N. Y., suddenly, from heart failure as a sequel of la grippe. He was 67 years of age.

Walter Butterbaugh, M.D., State University of Iowa, 1897, died at Denver, Colo., December 25, from tuberculosis contracted while in practice in Riverside, Iowa. He was 31 years old.

Alexander C. Reid, M.D., University of Aberdeen, Scotland, 1865, a retired physician of Hamilton, Ont., died at his home in that city, from paralysis, January 18, aged 63.

William J. Harris, M.D., Rush Medical College, 1866, a member of The American Medical Association, died at his home, near Beatrice, Neb., January 26, aged 80.

Gottleib Miller, M.D., College of Physicians and Surgeons, Keokuk, Iowa, 1882, a specialist on the eye and ear, died at his home in Ottawa, Ill., January 12, aged 76.

James Boyd McKelvy, M.D., University of Pennsylvania, 1848, was killed by a fall from a window, at his home in Bloomsburg, Pa., January 14, aged 70.

N. M. Bonham, M.D., Missouri Medical College, St. Louis, 1860, a pioneer physician and preacher of Missouri, died at New Franklin, Mo., January 18.

Henry Cotton, M.D., University of Minnesota, 1894, died at St. Barnabas Hospital, Minneapolis, from typhoid fever, January 22, at the age of 33.

Burt Andrews, M.D., Bellevue Hospital Medical College, 1891, died at his home in Augusta, Me., from tuberculosis, January 12, aged 32.

John A. Gilbert, M.D., University of Wooster, 1872, of Cleveland, Ohio, died January 22, after a prolonged illness from spinal disease.

Stephen M. Bayard, M.D., died at his home in Ionia, Mich., January 17, from pneumonia, after an illness of ten days. His age was 81 years.

George A. Landers, M.D., University of Cincinnati, 1883, of Van Buren, Ind., died from paralysis, at Fortville, Ohio, January 18, aged 42.

William F. Cook, M.D., Medical College of Ohio, Cincinnati, 1897, died from pneumonia, at his home in Latonia, Ky., January 17.

Albert L. Wagner, M.D., College of Physicians and Surgeons, Chicago, 1885, recently died suddenly at his home in Lapaz, Ind.

George E. Fullerton, M.D., University of Michigan, a retired physician of Marion, Iowa, died recently at his home in that city.

W. Frank Ross, M.D., Barnes Medical College, St. Louis, 1895, died at his home in Champaign, Ill., January 23, aged 44.

Lucius J. W. Lee, M.D., University of Pennsylvania, from pneumonia, at his home in Brooklyn, N. Y., January 8, aged 64.

Rollin E. Beach, M.D., Missouri Medical College, 1872, died from typhoid fever, at his home in Vandalia, Ill., January 23.

Thomas Henry McCormick, M.D., Harvard Medical School, Boston, at his home in Taunton, Mass., December 31, aged 25.

William H. Pleuthur, University of Buffalo, N. Y., 1891, was found dead, January 17, aged 31.

James Marcellus Watson, M.D., Jefferson Medical College, 1852, died at his home, near Fisherville, Va., January 16, after a prolonged illness, aged 70.

Therapeutics.

Treatment of Dysmenorrhea.

The general practitioner is very frequently called upon to prescribe for the ailments during menstruation. The *Ther. Gazette* gives the following outline of treatment by Lyon for dysmenorrhea: Absolute rest in bed for twenty-four hours preceding the expected period; applications of hot compresses or poultices to the lower portion of the abdomen. Rub the skin of the abdomen with the following liniment:

℞.	Ext. belladonnæ fl.			
	Ext. hyoscyami fl., āā	ʒi	4	
	Linimenti camphoræ	℥iii	96	

M. Sig.: To be applied externally.

In some cases rectal injections are recommended:

℞.	Tinct. opii	m. x		66
	Aquæ amyli, q. s. ad	℥vi	192	

M. Sig.: As an enema to relieve the pain; or:

℞.	Infusi valerianæ	ʒii	8	
	Aquæ, q. s. ad	Oi	500	

M. Sig.: As an enema.

If the menstrual flow is excessive:

℞.	Ergotin	gr. ii		12
	Quininæ sulphatis	gr. i		06
	Pulveris digitalis	gr. ss		03

M. Ft. pil. No. i. Sig.: Take one such pill two or three times a day; or:

℞.	Ext. hydrastis fl.	℥i	32	

Sig.: Thirty to sixty drops to be taken in sweetened water *once or twice daily*.

In other cases he employs the tinture of viburnum prunifolium in the following combination:

℞.	Tinct. viburni prunifolii			
	Tinct. piscidiæ erythrinæ, āā	℥ss	16	

M. Sig.:Twenty drops four or five times a day.

Piscidia is an unofficial preparation derived from the bark *of Jamaica dogwood.* Its action upon the nervous system is similar to opium. It is used as a nerve sedative and for the different forms of neuralgias. He also recommends the following for the same conditions:

℞.	Antipyrini			
	Potassii bromidi, āā	ʒi	4	
	Ext. viburni prunifolii	ʒiii	12	
	Spiritus vini gallici			
	Syrupi aurantii flor., āā	℥ss	16	
	Aquæ destil.	℥ii	64	

M. Sig. One dessertspoonful two or three times a day.

Antipyrin is preferable to other coal-tar products such as acetanilid, because it does not produce the changes in the blood that follow the administration of acetanilid. Brunton states that acetanilid must be used with care in the treatment of such conditions.

If the flow is not abundant but difficult, hot sitz baths to which mustard has been added is recommended, or mustard applied to the anterior abdominal wall. In such conditions he gives the following:

℞.	Asafetidæ	gr. ii		12
	Ext. valerianæ	gr. i		06
	Ext. cannabis indicæ	gr. ss		03

M. Ft. Pil. No. i. Sig.: One, two, or three a day; or:

℞.	Sodii salicylatis	ʒii	8	
	Rum	℥iss	48	
	Aquæ destil., q. s. ad	℥iii	96	

M. Sig.: One teaspoonful three times a day.

Chronic Alcoholism.

To meet the different symptoms present in chronic alcoholism Dr. Daniel R. Brower recommends the following outline of treatment to replace the stimulant:

℞.	Tinct. capsici			
	Tinct. nucis vom., āā	ʒiv	16	
	Tinct. cinchonæ comp., q. s. ad	℥iii	96	

M. Sig.: One teaspoonful every four hours.

TO PRODUCE SLEEP.

℞.	Chloralis hydratis,			
	Potassii bromidi, āā	ʒiii	12	
	Ext. glycyrrhizæ fl.	℥i	32	
	Syr. simplicis, q. s., ad	℥iii	96	

M. Sig.: One dessertspoonful at night.

Careful attention must be given to the nourishment and elimination. He advocates the frequent administration of beef tea well seasoned with capsicum. The beef tea can be made of some of the prepared and reliable extracts now upon the market. Elimination by the skin, kidneys and bowels should be carefully observed. For the latter he recommends the following as a cathartic:

R. Pil. cath. comp. Sig.: One or two pills as needed to keep the bowels in good condition.

Chapman recommends the following pill in chronic alcoholism:

℞.	*Zinci oxidi*	ʒi	4	
	Piperini	℈i	1	33

M. Ft. pil. No. xx. Sig.: One pill three or four times a day.

Acute Alcoholism.

The following combination is recommended by Gerhard:

℞.	Tinct. capsici			
	Tinct. zingiberis			
	Tinct. valerian. ammon.			
	Tinct. gentianæ comp., āā	℥i	32	

M. Sig.: One dessertspoonful in a cup of hot water three or four times a day.

Treatment of Delirium Tremens.

Dr. C. G. Stockton, in *Amer. Therapist*, advises the administration of an efficient purgative followed by:

℞.	Potassii bromidi	ʒi	4	
	Chloralis hydratis	gr. xxx	2	

M. Sig.: At one dose, unless the condition of the patient's heart should require a smaller dose. If it is deemed necessary the above dose may be repeated. For the heart, if it should show signs of failure, he recommends digitalis. Alcohol should not be permitted in any form, but in its stead stimulation and nourishment, as beef tea with capsicum. Strychnin and nitroglycerin may be of better use in some cases than digitalis. As a cathartic he recommends aloin in half-grain doses administered hypodermically. By this means good evacuation of the bowels will be produced. Hyoscin hydrobromate can be given in 1/100 grain dose to quiet the delirium, but should be used with great care and is of advantage only when the delirium is a temporary one.

Tubercular Laryngitis.

In the later stages of tubercular laryngitis the following insufflation for the relief of pain, which is usually severe, and the restoration of the voice, may be given:

℞.	Iodoformi	ʒii	8	
	Cocainæ hydrochloratis	gr. iss		09
	Morphinæ hydrochloratis	gr. ss		03

M. Sig.: A small amount to be insufflated by the patient with a bent glass tube to relieve the pain.

Treatment of Chlorosis.

Two of the important factors to be observed in the treatment of chlorosis, as in the secondary anemias, are rest in bed and the relief of constipation. It has been demonstrated clinically that the increase in hemoglobin has been as rapid in chlorotic girls who were put to bed with the proper attention to elimination by the bowels as in the cases where ferruginous preparations were administered and permitting them to follow their ordinary vocations. As a laxative, a pill containing aloes in combination with other drugs certainly takes the first rank. Aloes acts more especially upon the lower bowel. Colonic flushings, using the normal salt solution, should be resorted to occasionally. As hematinics, the iron and arsenic preparations take the lead. Dr. Frank Billings thinks the tinctura ferri chloridi is probably preferable to any other preparation in the treatment of the anemias. He recommends it to be given as follows:

℞. Tinct. ferri chloridi
Glycerini, āā ....ʒi 32|
Aquæ destil., q. s. ad....................℥iii 96|

M. Sig.: One teaspoonful three times a day, well diluted in water.

He further states that perhaps patients have some apprehension as to its effects upon the teeth when administered in the form of the tincture, although the decay is more probably due to the anemic condition of the patient. He emphasizes the importance of giving it in large doses. It seems that his statement is a proper one, if, as Wilcox states it, iron administered in any form is taken up by the system and circulates as the chlorid. Notwithstanding this statement, personal experience with the Fleischl hemometer in the frequent examination of blood has shown the great value of the Blaud pill in such cases, combined as follows:

℞. Ferri sulphatis
Potassii carbonatis. āā ....ʒi 4|
Acidi arsenosi ....gr. i |06

M. Ft. capsulæ No. xxx. Sig.: One capsule after each meal three times a day.

The organic preparations of iron which are upon the market certainly do not improve the blood as rapidly as iron administered as above.

Sir Andrew Clarke's idea that chlorosis is caused by gastro-intestinal stasis and resulting autointoxication has led to the employment of saline purgatives and intestinal antiseptics. He recommended the following:

R. Ferri sulphatis ....gr. xxiv 1|5
Magnesii sulphatis ....℥vi 24|
Acidi sulph. arom........................ʒi 4|
Tinc. zingiberis ....ʒii 8|
Infusi quassiæ, q. s. ad..............℥viii 256|

M. Sig.: Two tablespoonfuls twice daily; or:

R. Ferri sulphatis ....gr. xxiv 1|50
Sodii bicarbonatis ....ʒii 8|
Sodii sulphatis ....℥vi 24|
Tinct. zingiberis........................ʒii 8|
Spts. chloroformi ....ʒi 4|
Infusi quassiæ, q. s. ad ....℥viii 256|

M. Sig.: Two tablespoonfuls twice daily, at eleven and six o'clock.

For chlorotic amenorrhea, the following pill is well recommended:

℞. Ferri phosphati ....ʒi 4|
Pulveris aloes ....gr. xv 1|
Quininæ hydrochloridi
Ergotini, āā.........................ʒss 2|

M. Ft. pil. No. lx. Sig.: One pill four times a day.

This pill possesses the properties of a laxative, hematinic, tonic and uterine stimulant, all of which are certainly indicated in the treatment of such conditions.

Medicolegal.

Must Order Trial of Sanity on Physician's Affidavit.—The Supreme Court of Georgia holds, in Sears vs. State, that when a practicing physician has made an affidavit that a person who has been convicted in a superior court of that state for the crime of murder, and has been sentenced by the judge of that court to be hanged, has been by the affiant examined since the sentence and conviction, and discovered to be, at the time of the examination and of making his affidavit, insane, and in such mental condition that the question of his sanity should be tried before a jury under the terms of the law, and when this affidavit has been duly presented to the judge for the purpose of procuring a trial on the question of the sanity of such a convict by the superior court of the county in which he has been sentenced, it is the imperative duty of the judge to order such trial, and to have a jury impaneled, as provided by the statute, for the determination of this question.

Effect of Judgment for Services on Malpractice Case.—The Supreme Court of Tennessee was cited, in the case of Sale vs. Eichberg, to two apparently conflicting classes of cases as to the effect of a recovery by a physician of a judgment for services on a subsequent action by the patient for malpractice. An examination of these cases, however, the court says, will show that they are distinguishable in this important attribute: that, where the judgment for fees is by default, no estoppel, as it is called, arises—that is to say, the judgment is no bar to an action by the patient to recover damages for malpractice; but where there is a judgment for fees on the merits, or a confessed judgment, the matter is *res adjudicata*, as it is termed, and it will bar a subsequent action for malpractice. The supreme court also holds here that in a malpractice case where a practicing physician is called as a witness for the plaintiff and quite freely expresses his opinion in respect of good practice and proper treatment in such cases, the defendant is entitled to test the knowledge of the witness, notwithstanding he disclaims being an expert, by reading or having him read, extracts from standard medical works, on diagnosis and treatment in such cases, and asking the witness whether he agrees or disagrees therewith, and then by comparing his opinion with those of the writer. An instruction for the jury that the law fixes the standard by which the injury shall be measured in a malpractice case, which is "full and complete and ample compensation to the injured person," the court pronounces objectionable, in repeating, and thus emphasizing, to stimulate the jury in assessing damages beyond the rule of simple compensation; the true rule in such cases being compensation.

Construction of Warranty That No Brother Had Died.—The case of the Globe Mutual Life Insurance Association vs. Wagner was certified to the Supreme Court of Illinois as involving questions of such importance that it should be passed upon by that tribunal. An applicant for a policy of life insurance had been asked in his medical examination: "How many brothers dead?"—and answered, "None." At the end of the series of questions and answers, which included the foregoing, he signed a declaration and warranty that the answers were true, and that said answers and the statements made in his application, together with this warranty, should form the basis of any contract of insurance that might be entered into between him and the association. But the evidence, when the policy issued was sued on, showed that a brother of the insured had died in London, England, more than four years prior to the date of the application for insurance, though there was no evidence tending to show that the insured ever knew of his brother's death. Did this invalidate the policy? The Supreme Court of Illinois holds that it did not. It maintains that the answer here in question should be held to be a representation, and not a warranty, and that, in the absence of proof by the company of fraud or intentional misstatement on the part of the insured, the policy was not rendered invalid merely because the answer proved to be false. It says that, in the absence of explicit, unequivocal stipulations requiring such an interpretation, it should not be inferred that the insured or his mother, who was his beneficiary and also signed an application for the policy and made the agreements and warranties in the medical examination hers as fully as if she had signed the same, took a life policy with the distinct understanding that it should be void if any statements made in the medical examination should be false, whether the insured was conscious of the falsity thereof or not. Whether or not the insured knew of the death of his brother at the time of the application for insurance was a question for the jury. To hold that, as a precedent to any binding contract, he should guaranty absolutely that none of his brothers were dead would be unreasonable, in the absence of a more explicit stipulation than here appeared. It not infrequently happens that a man loses trace of all or a part of his relations, and to hold him to absolute guarranty that they were living, in order that he might obtain insurance, would sometimes be impossible, and almost absurd.

Disclosures in Death Certificate Privileged.—The Court of Appeals of New York holds, in the case of Davis vs. the Supreme Lodge, Knights of Honor, that, in an action on a benefit certificate, the cause of death of a relative of the insured, as of an aunt, can not be shown by the certificate of death filed by the attending physician. The court says that it has held that the statements of the attending physician, for the purpose of establishing the cause of death, either of the insured himself or of his ancestors or their descendants, although not parties to nor beneficiaries under the contract, are not admissible. They are excluded not only for the purpose of protecting parties for the disclosures of information imparted in the confidence that must necessarily exist between patient and physician, but on grounds of public policy as well. The disclosure by a physician, whether voluntary or involuntary, of the secrets acquired by him while attending upon a patient in his professional capacity, naturally shocks our sense of decency and propriety, and this is one reason why the law forbids it. The form in which the statements are sought to be introduced is of no consequence, whether as a witness on the stand or through the medium of an affidavit or certificate. All are equally under the band of the statute. Nor does the court consider that section 834 of the New York code, which expressly prohibits disclosures of information acquired by a physician in his professional capacity, when the relation of physician and patient existed, was repealed by implication by the provision in the charter of the city of New York of 1897, providing that the organization of the health department of the city, and that authenticated copies of the record of the proceedings of the board of health and books and papers constituting part of its archives shall be presumptive evidence in any court of justice or judicial proceeding, when they may be relevant to the point or matter in controversy. It may well be, the court says, that the records are competent to prove the fact of death, or prove marriages or births. It is quite possible that in some cases they might be competent on questions relating to pedigree. These facts could always, at common law, be established by a species of hearsay evidence; but the cause of death in a litigation between private parties, concerning the obligations of a contract of life insurance, must be established, when material, by common-law proof.

Indictment Where Practicing Medicine Is Defined.—Section 1477 of the Political Code of Georgia defines what persons shall practice medicine in that state. Section 1478 declares: "For the purpose of this chapter, the words 'practice medicine' shall mean, to suggest, recommend, prescribe or direct, for the use of any person, any drug, medicine, appliance, apparatus, or other agency, whether material or not material for the cure, relief, or palliation of any ailment or disease of the mind or body, or for the cure or relief of any wound, fracture, or other bodily injury or deformity, after having received or with the intent of receiving therefor, either directly or indirectly, any bonus, gift, or compensation." The indictment in Blalock vs. State charged the former with the offense of a misdemeanor, "for that the said O. C. Blalock, on the 24th day of August, in the year 1900, in the county aforesaid, did then and there unlawfully and with force and arms practice medicine, without then and there being authorized to do so either by diploma from an incorporated medical college, medical school, or university, nor after having attended one or more full terms at a regularly chartered medical college, having been in the active practice of medicine since the year 1866, nor being then and there authorized to practice medicine in 1866, nor having been then and there licensed by the medical board; contrary to the laws of said state," etc. Now, this indictment the Supreme Court of Georgia holds, not only substantially complied with the provisions of sections 485 and 486 of the Penal Code of Georgia, upon which it was based, but was not defective in not alleging that the accused did illegally practice medicine with the intent of receiving, or after having received, directly or indirectly, any gift, bonus, or compensation for his services in prescribing, suggesting, or recommending any drug, medicine, appliance, apparatus, or other agency for the cure of disease. It says that this indictment charged the accused with unlawfully practicing medicine. What "practicing medicine" means is defined by section 1478 above quoted. Every person is supposed to know the law. Therefore, the accused was presumed to have known what was meant by the term "practice medicine" under the state code. In other words, the court holds that since, by statutory defination, the words "practice medicine" embrace the idea of exacting compensation, an indictment charging that the accused did unlawfully "practice medicine," and expressly negativing his having any of the qualifications essential to the lawful practice of medicine set forth in Section 1477 of the Political Code, is good in substance, and will support a conviction, although there be no allegation that the accused received or intended to receive compensation.

Miscellany.

The Psychic Equivalent of Epilepsy.—Recently a contractor suddenly lost all remembrance of self-consciousness from Friday at noon in New York City until he found himself in the Buffalo General Hospital the following Wednesday evening. The last remembered by him is that, being worried about an invalid wife and also feeling mentally exhausted from a very trying political campaign, he entered the elevated train to go to his home in New York City. During the time of his loss of self-consciousness he undertook a railway journey from this city to Buffalo. He was found by the police, aimlessly wandering about the streets, and was sent to the Buffalo General Hospital, service of Dr. Charles Cary. During the time he was in the hospital, it was impossible to get any account from him, but he repeatedly called for his wife and for the senator in whose behalf he worked so assiduously during the campaign. Wednesday night he regained consciousness, and was much surprised to find himself in Buffalo. He gave a history of a father who died of apoplexy, and a brother who, as a young boy, had fainting attacks. He had himself, while driving last summer, struck his head, was unconscious for three hours, and had a paresis of the right side.

The Roentgen Ray in Military Surgery.—In the annual report of the surgeon-general of the army for the year ended June 30, 1899, it was stated that a special report on gunshot injuries, in which the Roentgen ray was used, was being prepared by Capt. W. C. Borden, assistant-surgeon, U. S. A. This has just been issued from the surgeon-general's office as a handsome quarto volume of 98 pages, with 38 plates and many other illustrations. Seventeen X-ray machines were available for use during the Spanish-American War; 5 were static and 12 coil machines operated by primary batteries. The former were considered best suited for work at permanent hospitals where no dynamo current was available; the latter for the base and general hospitals of war service. In the Spanish-American War the apparatus was supplied only to general hospitals and hospital ships. The reasons for not making use of it in the field-hospitals are stated as: 1. Lodged bullets require immediate removal only in extremely rare instances. 2. The environments of and conditions incident to movable field-hospitals render asepsis in operating practically impossible and, in consequence, in field-hospitals non-interference with wounds should be practiced to the utmost extent possible. 3. Surgical interference with lodged bullets, except where adequate asepsis is available or the necessity urgent, is to be condemned, as the suppuration which follows is much more detrimental to the patient than the presence of the lodged missile. 4. A Roentgen-ray apparatus in the field is an additional incentive to surgeons to operate under conditions not adequately aseptic. The report shows clearly that in non-infected wounds extensive comminution of bone is not as a rule an indication for operative intervention; that where there is infection complete cleansing of the wound and removal of all loose bone fragments followed by drainage, antiseptic dressings and irrigation, usually suffice, and that excision or amputation is to be resorted to only in extreme cases.

Idiosyncrasy Not a Factor in X-Ray Dermatitis.—R. Kienboeck, who has had years of experience with the *x*-rays at the Vienna Roentgen Institute, announces that the effects of Roentgen treatment, the causation of dermatitis, etc., vary with the kind of tube employed and not with the individual subject. The Roentgen rays which chemically affect the sensitized plate are the essential element in Roentgen treatment and, if in excess, the dangerous factor. Individual predisposition varies in very narrow limits; the young react more strongly than older persons. The quantity of the rays generated and their intensity, the duration of the exposure and the distance of the tube from the tissues, must all be taken into account. He accepts as a standard exposure that which causes a simple, transient alopecia, with *restitutio ad integrum* in four to eight weeks. Exposure producing an exudative inflammation is tenfold the standard, and exposure followed by an intractable ulceration is thirty to fifty times the normal standard. Rays of less penetrating power, such as are produced in soft and medium soft—"good"—tubes, have a more intense action than those from hard tubes: 1, because the latter send out less Roentgen rays, and 2, because they give a very penetrating light. He urgently warns persons occupied with the Roentgen treatment not to expose themselves in any way to the chemically active Roentgen rays, but keep out of their limited and well-defined range of action. He tabulates twenty cases of *x*-ray injuries, all but two published before. One of the latter is a confrère engaged in Roentgen therapy, who acquired a "Roentgen hand," which resulted in a deep, extensive ulceration of the back of the hand. It has resisted, for a year, all the treatments applied. The other case is an ulceration of the hypogastrium after exposure to a "good" tube for seventy-eight minutes in three sittings. Unna has recommended as a protective measure for operators the application of a thick coating of zinc jelly containing 10 per cent. cinnabar and bismuth oxychlorid.

Societies.

RIVERSIDE COUNTY (Cal.) MEDICAL SOCIETY.—This Society held its quarterly session at Riverside and elected Dr. Ashley S. Parker, president, and Dr. Louise Harvey Clarke, secretary, both of Riverside.

ROME (N. Y.) MEDICAL SOCIETY.—At the annual meeting, held January 15, Dr. Arthur A. Gillette was elected president; Dr. Howard J. Teller, vice-president; Dr. Thomas P. Scully, secretary, and Dr. Gilbert N. Lehr, treasurer.

BLACKHAWK COUNTY (Iowa.) MEDICAL SOCIETY.—At the meeting, January 22, at Waterloo, Dr. Ernest J. Waddey was elected president; Dr. Henry W. Brown, vice-president, and Dr. Fred W. Keehl, secretary and treasurer.

CLARK COUNTY (Ky.) MEDICAL SOCIETY.—At the January 12 meeting of this Society, Dr. Oliver R. Venable, Winchester, was elected president; Dr. R. Browne S. Ishmael, Winchester, secretary, and Dr. John A. Snowden, Wade's Mill, treasurer.

REDLANDS (Cal.) MEDICAL SOCIETY.—The annual meeting and election of officers was held January 15, with the following result: Dr. George H. Scott, president; Dr. Charles C. Browning, vice-president, and Dr. J. E. Payton, secretary.

SKAGIT COUNTY (Wash.) MEDICAL SOCIETY.—The recent election of officers resulted as follows: Dr. M. B. Mattice, Sedro-Wooley, president; Dr. Winston Appleby, Laconner, vice-president, and Dr. Charles C. Harbaugh, Sedro-Wooley, secretary.

RICHMOND COUNTY (N. Y.) MEDICAL ASSOCIATION.—At the annual meeting held January 14, Dr. Jefferson Scales was elected president; Dr. C. Wilmot Townsend, vice-president, and Dr. Henry C. Johnston, secretary and treasurer, all of New Brighton.

TAYLOR COUNTY (W. Va.) MEDICAL SOCIETY.—At the January 18 meeting at Grafton, Dr. Alfred R. Warden was elected president; Dr. Achbor J. Baker, vice-president; Dr. Rawley H. Powell, secretary, and Dr. William F. Van Kirk, treasurer, all of Grafton.

SPRINGFIELD (Ohio) ACADEMY OF MEDICINE.—At the meeting of the Academy, January 6, the following officers were elected: Dr. Theodore F. Bliss, president; Drs. Noah Myers and Stanley R. Hutchings, vice-presidents, and Dr. Charles L. Minor, secretary and treasurer.

WHITE COUNTY (Tenn.) MEDICAL SOCIETY.—At the January 8 meeting, Dr. I. L. Davis, Darkey Springs, was elected president; Dr. William B. Young, Bonair, secretary; Dr. R. E. Lee Smith, Doyle Station, corresponding secretary, and Dr. D. R. Gist, Sparta, treasurer.

NEW BRITAIN (Conn.) MEDICAL SOCIETY.—The members of the Society opposed to the hospital management, met January 15 and elected officers as follows: Dr. Herman Strosser, president; Dr. Robert M. Clark, vice-president, and Dr. Louis Smirnow, secretary and treasurer.

LACKAWANNA (Pa.) MEDICAL SOCIETY.—The annual meeting was held at Scranton, January 8, at which the following officers were elected: Dr. Walter M. Reedy, president; Drs. Addison W. Smith and Joseph F. Grant, vice-presidents; Dr. Lucius C. Kennedy, secretary, and Lowell M. Gates, treasurer, all of Scranton.

ATLANTIC CITY (N. J.) ACADEMY OF MEDICINE.—The annual election was held January 11. Dr. Edward A. Reiley was chosen president; Dr. J. Addison Joy, vice-president; Dr. A. Burton Shimer, secretary; Dr. Walter Reynolds, treasurer, and Drs. Edward A. Reiley, Elisha C. Chew and Albert D. Cuskaden, board of governors.

WASHINGTON COUNTY (R. I.) MEDICAL SOCIETY.—At the annual meeting, held at Westerly, January 17, Dr. William A. Hilliard, Westerly, was elected president; Dr. Rowland R. Robinson, Wakefield, first vice-president; Dr. C. Grant Savage, Westerly, second vice-president, and Dr. J. Howard Morgan, Westerly, secretary and treasurer.

WARREN COUNTY (Pa.) MEDICAL SOCIETY.—A meeting was held at North Warren, January 15, at which the following officers were elected: Dr. James Gass, Sheffield, president; Drs. Joseph J. Knapp, Kinzua and William M. Robertson, Warren, vice-presidents; Dr. James R. Durham, Warren, secretary, and Dr. William V. Hazeltine, Warren, treasurer.

DELAWARE COUNTY (Pa.) MEDICAL SOCIETY.—This Society met at Chester, January 12, and elected Dr. George D. Cross, Chester, president; Dr. Conrad L. Partridge, Ridley Park, vice-president; Dr. Linnaeus Fussel, Media, secretary; Dr. Daniel W. Jefferis, Chester, treasurer; Dr. Maurice A. Neufeld, Chester, reporter, and Dr. Samuel Trimble, Lima, librarian.

OPHTHALMOLOGICAL AND OTOLOGICAL SOCIETY OF WASHINGTON (D.C.).—The thirty-fifth session was held at the residence of Dr. William H. Fox, January 9, Dr. Stephen O. Richey, president, in the chair. Papers were read by Dr. William H. Fox on "Retinal Hemorrhage," and by Dr. Anton Coe on "The Use of Electricity in Ophthalmic and Aural Practice." Both were fully discussed by the members.

CUMBERLAND COUNTY (Pa.) MEDICAL SOCIETY.—At the meeting in Carlisle, January 8, the following officers were elected: Dr. Milton M. Dougherty, Mechanicsburg, president; Drs. George C. Borst, Newville, and David W. Camp, Plainfield, vice-presidents; Dr. Hildegarde Longsdorf, Carlisle, secretary; Dr. Enos K. Lefever, Boiling Springs, corresponding secretary, and Dr. John W. Bowman, Lemoyne, treasurer.

EASTERN OHIO MEDICAL ASSOCIATION.—This Association met at Steubenville, January 8, and elected Dr. Samuel B. McGavran, Cadiz, president; Drs. Walter S. Spence, Germano, Arthur B. Holland, Wellsville, John A. Hobson, Flushing, and Robert Laughlin, Steubenville, vice-presidents; Dr. James C. M. Floyd, Steubenville, corresponding secretary, and Dr. Joseph F. Purviance, Steubenville, recording secretary.

MIDDLESEX SOUTH DISTRICT (Mass.) MEDICAL SOCIETY.—The golden anniversary of this Society was held in Boston, January 16. The following officers were elected: Dr. Charles H. Cook, Natick, president; Dr. Eugene G. Hoitt, Marlboro, vice-president; Dr. Albert August, Cambridge, secretary; Dr. Walter Ela, Cambridge, treasurer; Dr. E. Scott Dow, Allston, librarian, and Dr. Alfred Worcester, Waltham, commissioner of trials.

BURLINGTON COUNTY (N. J.) MEDICAL SOCIETY.—At the annual election held in Mount Holly, January 18, the following officers were chosen: Dr. William P. Melcher, Mount Holly, president; Dr. Irving Hollingshead, Moorestown, vice-president; Dr. Addison W. Taylor, Beverly, secretary; Dr. Enoch Hollingshead, Pemberton, treasurer; Dr. Irene D. Young, Bordentown, historian, and Dr. Richard H. Parsons, Mount Holly, censor.

ALLEGHENY COUNTY (Pa.) MEDICAL SOCIETY.—At the quarterly meeting held in Pittsburg, January 15, the following officers were elected: Dr. John S. Mabon, Allegheny, president: Dr. Ferdinand Koeller, Pittsburg, vice-president; Dr. Clyde O. Anderson, Pittsburg, corresponding secretary; Dr. Edward Stieren, Pittsburg, recording secretary; Dr. Ewing W. Day, Pittsburg, treasurer, and Dr. Edward B. Heckel, Pittsburg, censor.

Lehigh County (Pa.) Medical Society.—The annual meeting and banquet were held at Catasauqua, January 8. The following officers were elected: Dr. Martin J. Backenstoe, Emaus, president; Drs. Albert J. Erdman and William W. Eschbach, Allentown, vice-presidents; Dr. Philip L. Reichard, Allentown, recording secretary; Dr. James L. Hornbeck, Catasauqua, corresponding secretary, and Calvin J. Otto, Allentown, treasurer.

Lycoming County (Pa.) Medical Society.—At the annual meeting, held at Williamsport, January 11, Dr. Joseph W. Albright, Muncy, was elected president; Dr. Robert H. Milnor, Warrensville, vice-president; Dr. Charles M. Adams, Williamsport, secretary, Dr. Wesley F. Kunkle, Williamsport, treasurer, and Dr. Horace G. McCormick, Williamsport, censor, Delegates to The American Medical Association and the State Medical Society were also appointed.

Berks County (Pa.) Medical Society.—At the annual meeting held in Reading, January 8. Dr. Samuel S. Hill, Wernersville, was elected president; Drs. Fremont W. Frankhauser, and Adam B. Dundor, Reading, vice-presidents; Dr. S. Banks Taylor, Reading, corresponding secretary; Dr. James W. Keiser, Reading, recording secretary, and Abraham S. Raudenbush, Reading, treasurer. Delegates to The American Medical Association were appointed on this occasion.

Cleveland (Ohio) Medical Society.—At the ninth annual meeting, held January 11, the retiring president, Dr. Henry S. Upson, in his address, strongly recommended that the medical societies of the city be merged into one and that the medical library building be the general headquarters. Dr. Charles F. Hoover was elected president; Dr. Henry W. Rogers, first vice-president; Dr. Robert Pollock, second vice-president; Dr. John N. Lenker, secretary, and Dr. John M. Ingersoll, treasurer.

Will County (Ill.) Medical Society.—At the meeting January 15, a committee was appointed, consisting of the president, Dr. Minnie K. Bowles, and the secretary, Dr. Ezra R. Larned, to consult with the senator and state representatives from this district regarding medical legislation in favor of needed reforms. The committee will choose a third member to act with it. Dr. Minnie K. Bowles, Joliet, was elected president; Dr. Roland H. Henry, Peotone, vice-president, and Dr. Ezra Reed Larned, Joliet, secretary and treasurer.

Texas Central Medical Association.—The fifteenth annual session of this Association was held at Fort Worth, January 8 and 9. The following section chairmen were selected: Dr. M. P. McElhannon, Belton, general medicine; Dr. William T. McNeill, Valley Mills, surgery; Dr. Scurry L. Terrell, Dallas, ophthalmology and otology; Dr. Hatch W. Cummings, Hearn, neurology and medical jurisprudence, and Dr. Frank D. Thompson, Fort Worth, obstetrics and gynecology. Dr. Nelson A. Olive, Waco, was elected president; Drs. Edgar D. Capps, Fort Worth, and William B. Anderson, Brownwood, vice-presidents, and Dr. William R. Thompson, Fort Worth, secretary-treasurer. Temple was selected as the next place of meeting.

CHICAGO NEUROLOGICAL SOCIETY.

Regular Meeting held Dec. 20, 1900.

Dr. Hugh T. Patrick, vice-president, in the chair.

Hematology of Neurasthenia.

Dr. Charles F. Lodor presented the results of a study in the hematology of neurasthenia. The article will appear in The Journal.

Polioencephalitis Superior.

Dr. Archibald Church reported a case of this affection in a male 31 years of age. The patient was a cashier and had been married five years, with no children. The family history presented several cases of tuberculosis; otherwise it was negative. The personal history was also without notable incident, and venereal history was denied. For several years, however, he had used alcohol and tobacco freely, working very hard, with short hours of sleep, but considerable outdoor athletic exercise. Aug. 19, 1899, in a very hot sun, he played golf all day, without any head covering. His forehead, face and scalp were severely burned and the hair bleached by the sun. On the second day thereafter he noticed dimness of vision in both eyes, was compelled to hold a book at a distance, and there was also a little double vision. Examination of the eyes by competent oculists failed to detect any trouble in the fundus. There was, however, a tendency to outward squint and some rigidity of the pupils. He was given mercury by inunctions. Two weeks later he came under observation, showing a slight ptosis on the left side, outward deviation of both eyes, and the pupils rigid to light and accommodation. Headache, vomiting, dizziness and other subjective disturbances were absent. The temperature, pulse, respiration, urine and blood were normal. He showed a little tendency to oversleep and, during the day, would drop asleep while driving. He also impressed others as being a little indifferent to subjects of ordinary interest, and was so as to the gravity of his condition. After twenty daily inunctions, a slight amount of disturbance appeared in the gums and the mercury was discontinued. On the thirtieth day after the onset of the symptoms, his speech was a little muffled and there was some incoördination when walking with the eyes closed. The tendon reflexes, which previously had been normal, showed increase, and there was a slight ankle-clonus on each side. During the night he had involuntary urination. On the thirty-first day the divergent squint subsided, apparently through paresis of the external recti or involvement of the nuclei of the sixth nerve, and the pupils commenced to dilate. Vision for distance was still normal, but there was no accommodative capacity and the pupils responded to neither light nor accommodation. Static ataxia was decidedly pronounced. The temperature had a slight subnormal tendency. There was mental hebetude. On the thirty-second day he was unable to stand, his pupils were dilated to the maximum, the eyes perfectly immobile, and ptosis on both sides partially developed. The temperature ran up to 100.2 F. The next day double ptosis was complete and reflex excitability greatly increased so that the patient was almost tetanized as he lay apathetically in bed. Babinski's sign was noted on both sides. The temperature was 101.2, and the pulse 120. The next day all conditions were worse and there was some difficulty in swallowing, with coma most of the day. The following day the temperature rapidly ascended to 108 F. with, at the same time, a falling pulse, and he died after twenty-four hours of absolute coma.

The post-mortem examination was absolutely negative, except that there were healed foci of tuberculosis in each apex, about as large as a walnut. An examination of specimens and serial sections was made by Dr. Fütterer, showing areas of more or less well-outlined softening in the corpora quadragemina, pons, peduncles, internal and external capsule, principally on the right side. The area in the external capsule involves the claustrum in its anterior portion, with an upward extension to the lower level of the cortex. The lesions in the peduncles are confined to their lower parts and are small, while others involve the nuclei of the oculomotoris, trochlearis and abducens. Changes are decidedly inflammatory and blood-vessels thickly surrounded by masses of leucocytes appearing in the midst of areas of degeneration. Here and there is also well-developed hyaline degeneration of the walls of the blood-vessels.

Dr. Church called attention to the fact that a series of cases showing graduations between acute polioencephalitis and asthenic bulbar paralysis or myasthenia gravis could be adduced from experience and the literature, and that in this case the sequence of events might perhaps be considered as follows: A tubercular lesion inducing some hyaline degeneration in the cerebral vessels; subsequently traumatism in the shape of sunburn; the action of toxic or infectious agencies producing inflammatory changes in an area of lowered resistance, and polioencephalitis with additional foci of inflammatory disturbance.

Dr. Church, in the formal discussion which followed his paper, suggested the possibility of a series of pathologic conditions in which polioencephalitis formed one end and myasthenia gravis the other.

Dr. Sanger Brown thought that this could hardly be the case, as the tendency of myasthenia gravis is toward recovery.

Dr. Hugh T. Patrick agreed with Dr. Church, and showed sections from a case which apparently occupied middle ground between the two conditions mentioned. His sections through various areas of the cerebrospinal axis everywhere showed vast engorgement of the capillaries and possibly some early degeneration of cells, the patient dying before further destruction had taken place.

CHICAGO PATHOLOGICAL SOCIETY.

Regular Meeting held January 14.

President L. Hektoen in the chair.

Tissue Changes from Diplococcus Scarlatinae.

Dr. E. R. Le Count made a report on the histologic changes found in the tissues of animals inoculated with diplococcus scarlatinæ (Class). The changes described differ only in degree from those described by Pearce and others in persons who die from scarlet fever, the most notable difference being the lack of lesions in the kidneys in the animals. Hyperplasia of lymphoid tissue, focal necroses and plasma cells in situations that betoken their presence in the blood were found in the animals inoculated.

Dr. W. H. Wilder read a paper on "Tuberculosis of the Iris," and showed specimens from a case observed by him.

Drs. D. R. Brower and H. Gideon Wells reported a case of paralysis of the cranial nerves of the left side, from the fifth to the twelfth inclusive. This paralysis had come on in the course of a few months and then remained stationary for twelve years. At no time were there pressure symptoms. On account of the history. coupled with a slight improvement under iodids and the occurrence of twelve miscarriages, a syphilitic lesion involving the meninges and producing an infranuclear paralysis was diagnosed. Death resulted from nephritis. At autopsy a tumor was found in the dura, exactly as located clinically, involving the left petrous bone. Microscopically it was found to be an endothelial tumor, the periendothelioma of Borrmann, with some spiculæ of bone and many multinuclear and uninuclear giant cells. Microscopically it somewhat resembled a psammoma.

Periosteal Chondrosarcomas.

Dr. Paul F. Morf presented gross and microscopic specimens of three periosteal chondrosarcomas. One of the tumors was from a boy of 13, and had developed on the tibia shortly after a contusion of that bone. The other two occurred in young adults, one in a female, aged 21 years, and the last in a male, aged 19 years. These two latter tumors were found to have grown from the lower end of the femur. Microscopically the neoplasms all appeared as firm, hard, inelastic, grayish-white masses. Scattered throughout their substance were numerous islets, which looked to the naked eye, like hyaline cartilage. Disseminated foci of calcification of pinhead size gave the cut section a slightly rough surface. Microscopically the tumors were found to be made up mainly of round and spindle-shaped sarcoma cells. The islets which appeared cartilaginous were made up of larger and smaller round encapsulated cells lying in a hyaline and in a fibrous intercellular substance. In the first of the three specimens the invasion of the Haversian canals of the tibia by sarcoma cells could be plainly traced.

NEW YORK ACADEMY OF MEDICINE.

Meeting of the Section on Surgery, held January 14.

The Field of Ethyl Chlorid Narcosis.

Dr. Martin Ware, in a paper on this subject said he had been able to collect records of 11,207 cases in which this form of narcosis had been employed. He had personally tested it in 200 cases of minor surgery, using as an inhaler the ordinary mouth-piece of the nitrous oxid gas apparatus, with the gas tube tightly plugged with cotton. The ethyl chlorid used was that known as the monochlorid, and it was best and most economically administered by an imitation of the drop method, i. e., spraying it intermittently on the gauze. Anesthesia usually occurs abruptly after one or two minutes, and except in neurotics and alcoholics, without struggling or excitement. In children, particularly a fair degree of relaxation was secured, which was more than could be said for adults anesthetized in this manner. From five to six grams were ordinarily required to produce anesthesia. Ethyl chlorid, when thus given, is cheaper than its chief competitor, nitrous oxid, and has the advantage of requiring no bulky apparatus.

Dr. Willy Meyer said that for the past two years he had been using ethyl chlorid in connection with the Schleich mixture of chloroform and ether, and had been much pleased with the results.

Dr. James P. Tuttle said that he had used ethyl chlorid as a preliminary to ether anesthesia in about 250 cases, and with such happy results that he believed this would be in the future its chief field of usefulness.

Meeting of the Section of Medicine, held January 15.

The Mosquito-Malaria Theory.

Dr. W. N. Berkeley read a paper entitled "Some Further Work on the Mosquito-Malaria Theory, with Remarks on the Conditions Around New York." Out of a large number of malarial patients examined during the summer, he had found only one who had apparently developed the malaria on Manhattan Island. As to the period of incubation between the bite and the chill, one case was presented in evidence, that of an intelligent woman living in East Seventieth street. She had not been away from New York City, but had spent one night with a sister at Fordham, and had there been bitten by mosquitoes. Just fourteen days later she had had her first chill. and her blood had been found swarming with the tertian malarial parasite. Inquiry showed that a number of members of this sister's family had suffered from malaria and had been relieved by taking Warburg's tincture. Last summer several cases of typical tertian malaria had developed in a town near New York City. Inquiry showed that they had been grouped around a pond, and that there were a number of segregated pools and post-holes at the edge of this pond. It had been suggested that, as far as possible, all anopheles found in that vicinity be destroyed systematically, and the smaller breeding-places be filled in. In addition screens were provided for the houses. It was recommended that the malarial patients should be secluded, and protected from the bites of mosquitoes as long as the malarial parasites remained in the blood. These suggestions had been carried out, with a most satisfactory result, not a single new case developing in that locality. The speaker was of the opinion that the board of health of Greater New York should require malarial cases to be reported like scarlet fever and diphtheria. An inspector should be sent to every infected house to instruct the people to kill the mosquitoes therein, provide screens for the windows and doors. protect the patients with netting and fill in neighboring pools of water, or else have them heavily petrolized. He was doubtful whether anopheles could be completely exterminated in this city because of the tearing up of the streets and the many sunken blocks, yet he was positive that much could be accomplished in this direction.

Treatment of Influenza.

Dr. William H. Thomson read a paper on this subject. He attributed the mild type of the present epidemic of la grippe to the fact that most of the people had previously had this disease, and had probably in this way acquired a certain degree of immunity. He had had the greatest success in its treatment by the following combination: 1/6 grain of the solid extract of aconite, 1 grain of Dover's powder, 8 grains of phenacetin and 6 grains of quinin. This is to be made into two pills, and 6 are to be taken daily so long as there is fever, and then the dose reduced to three a day until all catarrhal symptoms have disappeared. The obstinate paroxysmal cough so commonly observed after an attack of la grippe he had found to yield to a dose of 10 grains of antipyrin and 20 grains of bromid, and also to be greatly benefited by irrigation of the nose and throat with one quart of hot water in which has been dissolved 2 drams of chlorate of potash and 5 drops of the oil of peppermint. Perhaps one of the most important things to remember is that as soon as attacked with la grippe a person should take to bed and remain there until further orders from his physician.

Dr. Andrew H. Smith said that in a few instances he had been able, with the laryngoscope, to obtain a view of the bifurcation of the trachea in persons afflicted with the distressing cough that follows an attack of la grippe. He had found a velvety condition of the mucous membrane at this point. In efforts to relieve this cough his chief reliance had been on the internal administration of malto-yerbin. The physician should instruct his patients regarding the necessity of respecting the languor which they feel.

Dr. James K. Crook suggested that persons who were susceptible to bronchial affections should, whenever practicable, leave a region infected with influenza, and that where this could be done, as well as in those predisposed to infection with la grippe by reason of the exposure incident to their occupation, they should take small doses of whisky and quinin daily. For the first acute symptoms he makes use of 5 grains of phenacetin and 20 grains of bromid of sodium, at intervals of five hours. The severe muscular pains seemed to be best relieved by an occasional Turkish bath.

Dr. Morris Manges said that in la grippe cases he had almost invariably found, on auscultation, fine dry râles over the base of the lung posteriorly. A warm moist compress around the chest made these patients very comfortable. To avoid re-infection the patient should not remain too long in one room.

Dr. Brandreth Symonds said that in the early and severe epidemics of influenza the life-insurance examiners had been surprised to find that in as many as one in every ten persons, apparently healthy, and applying for life insurance, albuminuria was present. For the most part, this was transitory.

Dr. A. Rose spoke highly of the beneficial effects of the carbonic acid bath and the nasal douche of this gas in cases of la grippe.

Stated Meeting held January 17.

The Value of the X-Ray in Medicine and Surgery.

Dr. Francis H. Williams, of Boston, considered the x-ray in medicine, illustrating his remarks. He said that he uses in his x-ray work, a static machine having eight plates, each six feet in diameter, and with an adjustment by means of which the intensity of the light could be varied in order to bring out certain minute details that might otherwise wholly escape the observer. The patient is seated in a chair or placed on a stretcher, and the light placed about three feet from the fluorescent screen. Special care is taken that the source of light shall in every case be at a point corresponding to the intersection of a line joining the nipples and the median line of the body. In cases of emphysema the thorax appears lighter than normal, and the heart changes its position but slightly. In early tuberculosis the excursions of the diaphragm are shortened on the affected side, the heart drawn over a little to that side and there is a distinct increase in density. Not infrequently, as for example in cases of central pneumonia, consolidation of the lung is very evident on an x-ray examination, though it can not be detected by percussion and auscultation. An x-ray examination is very useful in cases of suspected aneurysm or new growths in the chest. Out of thousands of examinations he had not met with a single case of x-ray dermatitis.

Dr. Robert Abbe discussed the subject from the standpoint of the surgeon. In his experience x-ray examinations had proved most helpful in connection with fractures of the shoulder and injuries about the elbow. It had been the means of adding to our knowledge many new varieties of Colles' fracture, and enabled the surgeon to do far better work in this class of injuries. At the present time it is not a difficult matter to secure a good radiograph of fractures of the cervical vertebræ. He had found the method disappointing as a guide to bullets situated deeply in the tissues, owing to the difficulty of ascertaining the exact plane in which the bullet lies. It was very helpful, however, in the removal of needles.

Dr. Charles L. Leonard, Philadelphia, discussed "The Value of the x-ray in the Detection and Exclusion of Renal and Ureteral Calculi." In four of the patients he had examined there had been calculi in both ureters. Even the most minute calquli are capable of detection by this method, as was abundantly proved by the radiographs exhibited. The reading of the negative was, however, often the most difficult part of the diagnosis. The possibility of ascertaining the exact size and position of a calculus made it possible to estimate the chances of calculi being discharged spontaneously, and sometimes warranted the postponement of operative intervention. In 136 cases in which he had used the x-ray, renal calculi had been found in 17 and ureteral calculi in 19 cases.

Mr. E. W. Caldwell discussed "the Technique and Correct Interpretation of Radiographs." He said that the static machines are well adapted for fluoroscopic work and give a steady excitation of the tube, but if of sufficient power they are cumbersome and not very reliable. The most generally useful source for the x-ray is an induction coil capable of giving a ten-inch spark, provided with what is known as a *fluid interruptor*. At the patient's house, if a direct current electric lighting circuit is available, he makes use of this form of apparatus, but if there is no such circuit he passes a *lamp-cord out of the window* and connects it with the battery of an electric cab standing in the street. In making a radiograph of the thorax the chest should be strapped and the patient directed to employ abdominal breathing as much as possible. Similarly, in taking a radiograph of the abdomen, the latter should be bandaged and the patient told to breathe chiefly with the chest.

Dr. Walter B. James said that from a somewhat limited experience with the method in internal medicine, he felt that many general practitioners might very profitably make use of this new method of precision.

Dr. Carl Beck showed some skiagraphs of biliary calculi in the living subject—the first of the kind ever made. A "hard" tube and a coil giving a 15-inch spark should be employed for such work.

AMERICAN.

1. **Migratory Foreign Body.**—Kyle reports a case of attacks of frightful neuralgic pain occurring at intervals at different sites, at one time, suggesting mastoiditis, again facial neuralgia, again ethmoiditis, etc. Between attacks there was absence of any symptoms enabling one to locate the disease. The X-ray used to locate the foreign body produced acute dermatitis twenty-four hours later, with falling of the hair, the bad results of which were, however, temporary. While attempts at location were unsatisfactory, it was believed that there was a needle or piece of metal under the skin and this was vainly searched for with a magnet. An opening was made in the antrum, unsuccessfully, but was followed by swelling, apparently like a boil; this finally opened and the needle was extracted. The way the foreign body entered the tissues is unknown. Kyle knows of no such case in the literature with the peculiar features here presented.

4. **Examination of Infants.**—Two things should be borne in mind, says Herrman, in making examinations: 1. What is normal to the infant as against older children and adults? 2. Are there any abnormalities in this particular case under examination not due to the present illness? If such exist they may be either congenital or resulting from previous disease, and as illustration he mentions a yellow spot on the throat which was congenital though taken for a diphtheritic patch. The various points noted are physical characteristics, growth, size, temperature which is much greater than in the adult, and percussion and auscultation of the chest, the special points of which can not be given here, as they are noted in too much detail. The pulse, examination of abdomen, spinal column, mouth and throat should always be looked after. The stomach, genitals, ear, urine, feces, etc., are also noticed.

6. **Anesthesia.**—Palmer summarizes the indications for chloroform as follows: 1. In extensive bronchitis, bronchorrhea, pneumonia, or any extensive inflammatory condition of the pulmonary tract, because of its causing less irritation of the mucous membrane and less mucus to be secreted. 2. In acute and chronic nephritis, because it is less irritating to the kidneys. 3. In aneurysm, atheroma, endocarditis, and high-tension pulse, because it causes a perceptible fall in the blood-pressure. 4. In operations on the brain, because it causes cerebral anemia, while ether causes congestion and venous oozing. 5. In operations in the abdominal and pelvic cavities, because it causes a more complete relaxation of the abdominal muscles. 6. In those addicted to the use of alcohol and narcotics, because they usually take ether badly. In the hands of the inexperienced it is most dangerous on account of its depressing effects on the heart and lowering of the blood-pressure. Its dangers are immediate as opposed to those of ether, which are mostly in its sequelæ. The signs of danger are relaxation of the pupils, pallor of the face, sudden and rapid failure of the pulse and the respiration becomes feeble and intermittent. If any of these appear, the mask should be removed at once, and if they reappear when chloroform is again administered, ether should be substituted. Chloroform should always be given with the patient in the recumbent posture, which should be retained during the entire operation. Ether can be given in the sitting posture when necessary. It is indicated: In empyema with dilatation of the right side of the heart, fatty degeneration of the heart muscles and dilatation of the heart without compensatory hypertrophy; in extreme prostration and anemia; in shock, collapse and hemorrhage. When given under the latter conditions, heat should be applied to keep up the body temperature, as under narcosis there is a fall of from one-third to 1 degree. Very stout subjects should be given ether, as fatty infiltration of the heart has been found after prolonged chloroform anesthesia. One great advantage is that it can be given by the unskilled anesthetizer with greater safety and at the same time allow anesthesia to be more profound. Respiration is to be watched closely, as it kills by paralysis of the respiratory center. Collapse rarely occurs without warning. The symptoms are shallow, gasping respiration; small, rapid and irregular pulse, dilated pupils. If it causes persistent cough, with excessive amount of mucus or undue vomiting we should substitute chloroform. Precautions should be used with ether in operating at night by artificial light, as its vapor is inflammable. He also cautions particularly in regard to the need of admitting air, and in not giving the anesthetic in too concentrated form, also against beginning the operation when anesthesia is incomplete. When complete the pupils should be moderately contracted and remain so, respiration deep and regular, and the pulse slow, though it may be rapid without danger unless it becomes weak and irregular. There should be a general muscular relaxation. The dilated immovable pupil indicates danger, and sudden wide dilatation of pupils calls for immediate measures. When vomiting seems to be inevitable we should remove the inhaler, lower the head and turn it to one side, and draw the jaw forward by pressing behind the angles. As soon as the patient is quiet we should cleanse the mouth and pharynx and then administer the anesthetic. Directions for resuscitation and stimulation are given, also the after-treatment. The patient should be continually watched until consciousness has been regained. If recovery does not occur within sufficient time, hot-water baths are indicated, and stimulants, and if much loss of blood has occurred normal saline solution should be infused. It is good practice to give a hot colon injection of about one quart of warm normal saline solution after prolonged operations. It lessens the thirst and shock, stimulates the kidneys and brings the patient out earlier and more satisfactorily. Vomiting should be treated by inhalation of fumes of vinegar as long as necessary. For the first twelve hours nothing should be allowed to enter the stomach.

9. **Perforation in Typhoid.**—Among the complications of typhoid, perforation is the most formidable, and Osler expresses the opinion that it is remarkable that it does not occur more frequently when we consider the extent and character of necrotic processes. The all-important question is to recognize its occurrence and, if possible, operate before widespread general peritonitis is produced. He reports several cases in which the accident occurred and where operation was performed, in one of which, however, it was incomplete, while in the other two it was a success. He gives a schedule of specific instructions to be followed in cases of typhoid fever in which perforation is suspected. He thinks if the attending physician would notice all these points much may be done to reduce the mortality. He gives detailed instructions concerning these cases, and the necessity of watching for the first feature of perforation is emphasized.

10. **Hemoglobinuria in Typhoid.**—In the cases reported by Kelly and Musser there was hemoglobinuria observed from the beginning and lasting for seven days. The progress of the disease was favorable. Aside from the rarity of the complication, other facts noticed are absence of malaria as an etiologic factor, and the use of cold-water baths with good results when it is known that cold is certainly the provoking agent of some cases of hemoglobinuria, especially the paroxysmal type. The authors think there can not be much doubt that the symptom was an unusual manifestation of typhoid infection; the case was not severe unless these symptoms should be considered in that connection. It is not unreasonable to assume that the patient had a peculiar idiosyncrasy, making his hemoglobin and red corpuscles especially susceptible to the action of typhoid toxins.

11. **Thermol.**—Shimer has experimented with thermol ($C_{11}H_{15}NO_3$) and reports cases with temperature curves showing its effect. He remarks that in each of these typhoid cases the temperature curve was markedly dissimilar to typical typhoid temperature, and the specific action of thermol on the fever is, he thinks, evident, from his observations in hospital cases as well as in private practice. He believes the earlier thermol is administered the better the result. As an antipyretic it is harmless and can be given at any time or under any conditions, any harmful effects such as collapse never being noted. The mode of administration is .5 gram at intervals of every two or three hours and to be given when the fever commences to rise, and continued even after it has disappeared, in smaller doses and at longer intervals.

13. **Atropin Poisoning.**—This experimental investigation of Reichert's gives the different stages of atropin poisoning, particularly as observed in the effects on the respiratory and vasomotor centers. The whole shows the extraordinary power of recovery of the system from the action of atropin. In one experiment recorded, 1.5 grams of atropin, or over six times the minimum fatal dose, was given in divided doses. Two hours after the first injection feeble respiratory movement occurred, there was a return of reflexes, the pulse-rate was higher than immediately after the first injection and arterial pressure had increased about four-fold. Fifteen minutes later respiratory movements were sufficiently frequent and deep to dispense with artificial respiration. In the second experiment over seven times the minimum fatal dose was given and the same strong general tendencies were manifest. Among other actions, the effects of large doses on the motor and sensory nerves are positive, both being completely paralyzed during the second period. A curious fact shown by these experiments was that while the motor fibers are absolutely inexcitable to faradic stimulus, they retain their conductivity. These experiments have an important bearing on the treatment of poisoning in man, as they show that death is due to paralysis of the respiratory center, that the center has great recuperative power, and that if artificial respiration be properly practiced the respiratory center recovers its activity, which is accompanied by general and marked improvement of the other depressed states. In man it seems that atropin poisoning should be readily treated with artificial respiration, persistently and intelligently practiced, as by Laborde's method, accompanied by such other treatment as the indications suggest.

16. **Mosquito Theory of Yellow Fever.**—Finlay reproduces a portion of an article, dated Dec. 31, 1891, which has never been published in full, though portions of it were sent to the congress at Chicago in 1892. He believes that the recent experience of the army yellow fever board has placed beyond the question of a doubt the fact that the culex mosquito, fasciatus, does transmit yellow fever to non-immune persons so well isolated from other sources that the infection could be considered a certain result of inoculation. He also thinks it noteworthy that these bear out one of his former statements, that, whereas one or two stings from a mosquito recently contaminated may cause a mild attack of the disease or simply confer immunity without any perceptible pathogenic manifestations, the severer attacks result from a greater number of such stings, and the same might follow a single sting from a mosquito exclusively fed, during several days or weeks after its contamination, on sugar or sweet juices. Another important point which the army board has noticed and has undertaken to demonstrate, experimentally, is the fact that the other sources to which the yellow fever has been hitherto attributed are absolutely incapable of determining the attack of the disease.

17. **Ovarian Grafting.**—Morris reviews the subject of ovarian grafting in detail. Cases are given, two of which have been previously reported, and in one of the cases, after transplanting a portion of the patient's ovary and excision of the remainder, the patient became pregnant, but lost the child by aborting in the third month, presumably because of the presence of persistent pelvic adhesions. In several other cases the ovaries were transplanted from one patient to another and menstruation re-established. In his earlier experiences the ovary was sometimes grafted into a slit in the fundus so that the uncut surface projected into the lumen of the uterus. In his later cases he has chosen the broad ligament as a site for grafting, as nearly as possible at the point that the ovary would normally occupy. The best result of ovarian grafting, in his experiments to date, is the avoidance of the menopause. Several successful pregnancies have been observed in rabbits by other experimenters, but we have yet to see a similar result in women as a result of the operation. The paper concludes with a review of the experiments of other investigators. The dangers from ovarian grafting seem to be no more than those from simple uncomplicated laparotomy.

19. **Spinal Cocainization.**—Twenty-one cases of subarachnoidean cocainization in obstetric and gynecologic cases are reported by Hawley and Taussig. The results tend to support the view that the method is not very dangerous, except perhaps to the child *in utero*. In 5 of the 21 cases the cocainization seemed to have a toxic action on the child. The pulse that was 140 would drop to 90 or 100 after the injection and, remaining so for about ten minutes, would begin to return to normal. Three times the child was somewhat asphyxiated when born. One child died, but death was not attributed to this, as it showed signs of weakness previous to the injection. In no case was there any post-partum hemorrhage. When it produces disagreeable symptoms they are usually transient. In labor cases it usually retards the progress. From a study of the cases the use of lumbar puncture in multiparæ would seem to be less called for than inhalations of chloroform. The results obtained from its use in primiparæ were not very encouraging. In instrumental deliveries, when urgency is required and the patient not of a very nervous temperament, the spinal narcosis seems to meet every indication. The delivery would then be much facilitated by the patient's aid, which would be impossible under general anesthesia, and the dangers of retained placenta and postpartum hemorrhages are lessened. The authors conclude that it is doubtful whether puncture will ever replace general narcosis in abdominal operations. In vaginal celiotomy and minor gynecologic work it seems to have its greatest field of usefulness.

20. **Pulmonary Tuberculosis.**—Upson thinks that the need of greater personal attention to consumptive cases is manifest, and if the general practitioner could give the same care to these that he does to his cases of pneumonia the mortality would be lessened. He lays little stress on heredity, and believes that when several members of a family contract the disease it can usually be traced to infection. Twenty-five years' experience has convinced him of the curability of many cases. If the disease is a localized one, or even in both lungs, and the digestion and assimilation are or can be made good, sleep is restful, the environments healthful, and the patient is possessed of a determination to get well, a favorable prognosis can be made. Examinations should be extremely careful and thorough if success in the treatment is to be expected. The special points in the treatment are noticed, the use of light, ventilation, disinfectants, care of the sputa, cleansing of the intestinal tract in the beginning, tonics, systematic exercise, cold sponging and attention to hygienic environments generally. The author is inclined to look favorably on intrapulmonary medication, the frequent use of a mixture of eucalyptol, pine-needle oil, menthol and formic aldehyde having proved in his hands the most beneficial of the remedies he has tried.

21. **Diphtheria Antitoxin.**—To obtain the best results from antitoxin Koester says it must be used fearlessly and in effective quantity, which is never less than 2000 units, and in severe cases at least 3000 must be used, and this dose repeated in from twelve to twenty-four hours. Antitoxin in itself never does any harm and a supply with an appropriate syringe should be a part of every physician's armamentarium whenever he goes to see a patient of whose condition he knows nothing. The dose is to be regulated by the severity of the disease and its duration. There are also other features to be considered and, in cases of diphtheritic croup, very large doses should be given, 4500 to 6000 units, and we should be ready to intubate

at a moment's notice. Another advantage is its immunizing action, thus enabling us to prevent the disease spreading. The accessory treatment is noticed and the effect of complications. The author believes that rash following the use of antitoxin is due to excrementitious salts in the cells of the horse's serum, and if they were eliminated its occurrence would be prevented. He says: 1. Antitoxin is a positive cure for diphtheria, when employed in sufficient quantity and sufficiently early in the disease. 2. Even when employed too late in the disease to produce its specific action, it can not under any circumstances be productive of harm. 3. When used before the invasion of diphtheria, antitoxin possesses a positive immunizing power which lasts about thirty days.

22.—See abstract in The Journal, xxxv, p. 1171.

27. **The X-Ray in Cancer.**—Williams states his conviction that the X-rays are of value in the treatment of certain forms of epidermal cancer. His experience indicates that we have either in the X-rays themselves, or in some other form of radiation from the Crooke's tube, a valuable therapeutic agent in epithelioma, the beneficial action of which may be brought about without causing a burn. The earlier the treatment is undertaken the better. It is not improbable that we may find its curative action limited to superficial growths, though as a means of relieving the painful features of disease in other forms it may be of some use. In cases where it is effective the odors disappear, discharge decreases and the growth steadily diminishes in size.

31. **Appendicitis.**—The conclusions with which Wiggins ends his article, and which he claims are incontrovertible, from surgical experience, are: 1. There is a period during the attack when, if properly investigated, most cases can be diagnosed. 2. In some cases the real condition may be so masked by intercurrent troubles as to require an explorative incision for its solution. 3. Some cases may be simple and some severe, but no one can state in any given case, no matter how simple to-day, what the conditions will be to-morrow. 4. There is a period in every attack when the appendix can be removed with perfect safety; and there may occur a time in any attack when life is jeopardized either with or without its removal. 5. The same judgment we exercise in ordinary business affairs, if applied to a diseased appendix, would suggest its removal at the earliest moment compatible with proper preparation.

39. **Vesiculitis.**—The anatomy of the seminal vesicles is described by Morrow and the pathology of their inflammation discussed. He recognizes three classes of this disease: 1. Those caused by sexual excesses or other sexual irritability. 2. The gonorrheal type. 3. The tuberculous, which may be combined with the gonorrheal. The development of this disease, unless it takes on the acute type, is insidious, but the suspicious symptoms are frequency of urination, feeling of fullness and stiffness of the parts, perineal pain, sacral pain, various disturbances of the sexual functions, bacteria in the urine, other sources having been excluded, etc. The diagnosis must be by exclusion of stricture, posterior urethritis, prostatitis, spermatorrhea, cystitis, and pyelitis, but the only really effective means is digital examination per rectum by the educated finger. The tuberculous type can not always be excluded, but the evidence of tuberculosis elsewhere will clear up the case. The prognosis is usually good if the patient is of middle age or good physique. In older persons and in tuberculous cases the prognosis is not favorable. The only treatment of simple and chronic vesiculitis is stripping the vesicles, the method of which is detailed. He advises against the use of too much force and the employment of special care in chronic cases to avoid hemorrhage. In most instances no other than this method is required. Occasionally it may be necessary to give potassium bromid as a sedative or tonic. The treatment may cover from six weeks to six months. The stripping should not be undertaken too soon after an attack, nor continued if it increases the tenderness. In the tubercular type it is almost invariably contraindicated and we should use only tonics and antitubercular remedies.

40. **Strophanthus.**—Mabem has taken the testimony of various physicians in regard to the action of strophanthus, and found a great variation of opinion, some finding it useless, others considering it an indispensable drug. In this connection he calls attention to the importance of physiologically testing drugs before their use. The failure to do so may incur serious disappointment and loss of faith in the remedy.

41.—See abstract in The Journal, xxxv, p. 1663.

42. **Infantile Plantar Reflex.**—Morse's article is a study of the statements of others who have observed this reflex in children, and apparently, also, his own observations. His conclusions are: "It is evident, therefore, that there is no constant plantar reflex during the first year, and that while the reflex approaches the adult reflex during the second year, it is still inconstant. It is also evident that since there is no constant reflex under normal conditions during the first two years, no conclusions can be drawn from the presence, absence or character of the reflex in the diagnosis of abnormal conditions of the nervous system at this age. Further observations are necessary to show at what age the normal reflex is established. It is undoubtedly later than the second year."

46. **Acute Aural Empyema.**—The question whether the antrum should be opened in acute empyema is considered by Snydacker, who reviews the various authorities. Operators in such conditions may be divided into two classes: 1. Those who open the antrum in all acute empyemas of the mastoid cells. 2. Those who open the mastoid cells without opening the antrum. Possibly a third may be added which occupies an intermediate position between the two. As an exponent of the second class he quotes Politzer, who finds in the majority of his cases no connection between the abscess and the mastoid antrum, and as an exponent of those who would open the antrum in all cases he quotes Schwartze, and as one of the intermediate class, Hessler. His own study as to the advantages of the two methods leads him to render a favorable opinion of the Schwartze treatment, though he asks: Is there a means by which we can combine the two methods? The rules which Urbantschitsch has laid down when the antrum is to be opened in acute empyema are sound, and an operator would be taking many chances to disregard them. If the meningeal symptoms are prominent, if the fistulæ lead toward the antrum, if the posterior wall of the meatus is bulged forward, or when signs of inflammation are localized in this region, then in every case the antrum should be opened. In answer to the question whether, when none of these symptoms are present, it is safe to leave the antrum alone, he says the operator, unless he makes a routine practice to open it, must ask himself: 1. Is it drained? 2. Has it undergone such pathogenic changes that it is a focus of infection? If he is in doubt as to either of these points he must open the antrum. What can or should be avoided, however, is useless curetting of the antrum and aditus. Every time the antrum is opened in acute empyema the first opening should be merely exploratory and as small as is consistent with exploration of the cavity. If there is no empyema of the antrum, no growths nor other pathologic changes, to open it wider and enlarge the cavity so that the abscess is constantly reinfecting itself would seem absurd. If when it is opened no pus wells up, and on careful examination with a probe and by inspection no pathogenic changes are found, then the relations of the parts should be disturbed as little as possible. In this way we can, to a certain extent at least, combine the advantages of the Politzer method with those of the Schwartze.

47. **Pharyngeal Tonsil.**—Wex describes the anatomy of the part and then reports seven cases of tuberculosis, in six of which tubercle bacilli were found, a larger proportion than seems to have been observed by any others.

48. **Aural Complications of Scarlet Fever.**—From his observations von Gaessler comes to the conclusion that there is a relation of middle-ear disease to the exanthem. Simple hyperemia, secretory process, fibrous exudate, form the progressive states of ear disease due to infection. He thinks that ear disease is the usual manifestation of general infection and

not extension of the infectious process in the condition. While the relatively small number of the examinations he has made only suggests the probable invariable participation of the ear in scarlet fever, they show that pronounced inflammatory processes can exist behind the normal or nearly normal drum membrane. In scarlet fever the condition seems analagous to measles and diphtheria in which the ear invariably participates.

58. **History of Typhoid Fever.**—According to Haskins, typhoid fever can be recognized in the literature for over 200 years. Its nature, as distinguished from typhus, has been universally recognized for exactly fifty years.

59. **Etiology of Typhoid Fever.**—The definite cause of typhoid fever is recognized to be bacillary, which appears not merely in typhoid, but in other conditions, as for example leptomeningitis, cholecystitis, and puerperal fever. It is of great importance to recognize the fact that this germ is a possible cause in cases of bad septic or acute inflammatory and other lesions without the characteristics of typhoid. We must, therefore, modify our older views and define typhoid as an infection by the bacillus typhosus. So far as Howard is aware, very little is known as regards individual susceptibility. Certainly not all who are exposed are infected, and one attack usually gives lasting immunity.

60. **Diagnosis of Typhoid.**—According to Hoover, the spleen is universally enlarged in typhoid, and he would hesitate to diagnose the condition where it was not evident. The common method of percussion may not be able to determine it. The better method is to define the position of the spleen by the resistance it affords to the percussing finger, by a sort of palpation rather than percussion. Ileocecal tenderness is another sign which is usually sought in an inaccurate manner. The local peritonitis over the site of intestinal lesions would cause pain, but if tenderness is to be elicited from the ulcerating mucosa of the intestine, it must be opposed against the posterior abdominal wall and then pressure exerted to produce pain. The diseases to be distinguished from typhoid are trichinosis, malaria, septic endocarditis, septicopyemia, meningitis and miliary tuberculosis. The last is the one which we have to distinguish far more often than any other disease. As often as any other sign, the dicrotism of typhoid assists in recognizing the disease. Another constant sign is diminution of the white corpuscles, the hypoleucocytosis. The Widal reaction is found also in miliary tuberculosis, in malaria, and in some cases of sepsis. He sums up the most constant signs as continued fever, flushed face, dicrotic pulse, large spleen, ileocecal tenderness, hypoleucocytosis and the Widal reaction.

61. **Prognosis in Typhoid.**—In the modern uncomplicated case Rogers says the prognosis is good. The conditions that make it unfavorable are persistent high temperature, often up to 103 or 104 F. Laryngitis, especially when it takes the type of perichondritis, is usually fatal. Pneumonia is another serious complication; ulceration can not always be determined. Meteorism adds to the gravity of the case and, if excessive, is an unfavorable sign. Hemorrhages are dangerous in proportion to the amount of blood lost. The prognosis of perforation is always bad. Early insanity is usually fatal, and profound coma is likewise a bad symptom. In cases where the nervous system seems to receive the force of the poison and in proportion to the impression and persistence of it in spite of the treatment, the prognosis should be guarded. The heart suffers in different degrees; there are few cases without some sign of weakness in the middle or later periods, and sudden death may result from very mild exertion. The circulation is an important element in forming our prognosis, and the latter is never to be made absolutely safe until all signs of cardiac disturbance have disappeared.

62. **Management of Typhoid.**—The chief points insisted on by Lee are early confinement to bed, good atmospheric conditions, disinfection, free administration of pure water, care of mouth and teeth, prevention of bed-sores and good nursing.

63. **Feeding in Typhoid.**—Carter reviews the recent literature of feeding in typhoid and points out the inconveniences of an exclusive milk diet, and on the whole, the better showing is in favor of a rather liberal diet, though some statistics show more percentage of relapses, and due caution should be used. He says, in view of the long siege which lies ahead of the typhoid patient, that every means which may be safely used to save the strength should be employed.

64. **Sequels of Typhoid.**—*Those mentioned here by Maynard* are temporary alopecia, bed sores, pustular dermatitis, which he has observed in one case, mental defects from disturbance of nutrition of the brain and cord, thrombosis of the femoral vein coming on after the patient begins to improve, myocarditis, pneumonia, bronchitis, laryngitis and nephritis. Tuberculosis may develop after typhoid, but the question then arises whether it was not the primary disease.

70. **Uric-Acid Lesions.**—Deficient oxygenation and excessive nuclein-catabolism, according to Croftan, produce a growth of toxic leucomains called the alloxuric bases, which are the true poisons in uratic lesions. Uric acid acts pathogenically only from its tendency to form concretions; the alloxuric bases entering the blood-current prepare a nidus for the deposit of these concreations, which in their turn act as mechanical irritants in the different tissues, in the joints as in gout, and in the kidneys. *The indications for treatment* are: 1. To raise oxygenation, which can be done by oxygen inhalations, and in addition to this iron and arsenic, together with hygienic measures, such as massage, hydrotherapy, electricity, regulated diet, etc. 2. To regulate nuclein-catabolism, and this is chiefly done through regulation of the diet, in excluding foods which contain nuclein or alloxuric bases. Thus internal organs such as the spleen, liver, sweet-breads, kidneys, brains, etc., are forbidden. Soups, meat extracts and broths are unadvisable. Raw, dried, cured and smoked meats are to be condemned; boiled, fried and stewed meats are permissible. The starches, sugars and fats are harmless as long as they do not disturb the digestion. Alcohol is absolutely harmful. Tea, because of some of its alkaloids, is forbidden, but coffee is harmless. Water can only act beneficially. 3. *The elimination* of alloxuric bases and soluble urates and, on account of the very irritating action on the kidneys, Croftan prefers to avoid diuretics and promote sweating by hot baths, massage and friction treatment. The salicylates, being diaphoretics, are also useful in this way. The alkalies act similarly and also neutralize lactic acid. The so-called specifics, guaiacum, colchicum, potassium iodid, etc., are uncertain in their action and he does not use them. 4. This indication is the removal of uratic secretions. *The so-called solvent action of certain agents is altogether fictitious.* The theoretic remedies used in these cases are not yet established. The best treatment of the mechanical condition is necessarily mechanical. He employes counter-irritation, heat and cataphoresis for this purpose. Cantharidal collodion painted over the inflamed point often relieves pain and lessens irritation, and heat can be applied with a simple apparatus made with a stovepipe and lamp as well as with the more expensive ovens so generally advertised. Cataphoresis is indicated in chronic cases of gout with old deposits. The fingers and knuckles being elaborately cleaned and wrapped with borated absorbent cotton moistened with a solution of iodid of lithium, are placed on a metal plate connected with the negative pole. Above the fingers is placed a metallic electrode of the galvanic battery connected with the positive pole. About 20 milliamperes, for ten minutes, are sufficient, massage of the joints following. As the uratic diathesis is a hereditary condition, its cure in one generation is not to be expected. We are limited to an intelligent prophylaxis, carefully regulated mode of life, and treatment of special manifestations. In this way the perversion may possibly be educated back to the normal.

88. **The Schott Treatment.**—Turner's article is a severe criticism of the methods at Bad-Nauheim, in which he arraigns Professor Schott, whose name has been attached to this well-known bath and gymnastic treatment of cardiac diseases, as an advertising charlatan, and gives instances which he thinks show his unreliability, ignorance and cupidity. He finds, he says, also, by inquiries among medical men in Germany, that this idea is largely held in regard to him.

102. **Invalid Diet.**—Irwin thinks that fevers are underfed and gives his own experience in using a more liberal diet than has generally been recommended. Twenty cases of typhoid fever in which were allowed dry toast, soft poached or boiled eggs, etc., as soon as they showed any appetite, contrasted favorably with twenty-five cases in which milk was the chief diet and soft toast only allowed after a normal temperature had been maintained for two days and stopped if it rose again. The question, he says, is not one of solid or liquid food, but one of digestibility.

103. **Mastoiditis.**—From his experience, a sample of which is given in a report of seven cases, Tuttle sums up the treatment of mastoiditis as follows: In all cases of purulent otitis media there is more or less involvement of the antrum. In acute otitis media with symptoms of mastoiditis we are justified in using palliative measures for twenty-four hours. To delay operative measures more than twenty-four hours without marked improvement is, however, not justifiable. The incision in the posterior superior wall of the auditory canal is far superior to Wylde's incision as a depleting measure. All cases of chronic purulent otitis media resulting in mastoiditis should be operated on at the first appearance of symptoms without resorting to palliative measures, and the author claims that we are justified in opening the antrum for drainage in chronic cases of this condition without symptoms of mastoiditis.

105. **X-Ray.**—Horsky discusses the fallacies of the X-ray, showing that skiagraphs are not entitled to the credence given to ordinary photographs. He has also corresponded with several prominent surgeons concerning the status of the X-ray in legal medicine, and has obtained no positive reply. There appears to be much diversity of opinion in regard to it among surgeons, though few judges have objected to it. He maintains that the skiagraph in any case should be taken by an expert. The physician should accompany his patient to the examiner, or, if he himself takes the photograph, a witness should be present. Before taking the picture both parties should verify, with the fluoroscope, the anatomic position of the part with reference to the plates and tubes, and it is also necessary that the part be taken in several positions. If the picture is introduced in evidence, or if its exclusion is attempted, the examiner should be required to demonstrate in detail just how it was taken. Finally, it being perfectly practicable, the apparatus itself should be brought into court and the jury be allowed to examine the part with the fluoroscope. He thinks the time is not far distant when this method will be in vogue. In conclusion he suggests the following as an ethical consideration for the physician or surgeon: If ever occasion requires one to take a skiagraph of a case treated by another physician, do not under any consideration allow the patient to get hold of the picture, for should any deformity or abnormality, real or fancied, appear, it may act as an incentive to bring an action. If a photographer is employed he should be charged not to give out any copies of the picture except to the physician.

108. **Fallacies in Rectal Surgery.**—The fallacies mentioned by Matthews are the use of the long tube in the diagnosis of rectal disorders and the existence of rectal valves. He quotes a number of authorities to support the opinion that these valves do not exist. He says he has looked for them for years and has yet to find them.

110. **Neurasthenia.**—Pope's summary of the treatment of neurasthenia is: 1, rest—curtailment of energy; 2, partial rest; 3. exercise; 4, diet; 5, insistence on drinking large quantities of water; 6, massage; 7, electricity; 8, hydrotherapy.

116. **Insane Asylum Laboratories.**—Barker considers the special subjects of pathology and bacteriology and their study in institutions for the insane, and enumerates the advances and results in these studies. He makes a special point of the importance of clinical work in these, and the co-operation of such with laboratory investigation.

117. **Constitution.**—Bell offers a vitalistic theory of the phenomenon of organic life, and defines what we call constitution "as an individual peculiarity of co-operative and reciprocal work of life." That is to say, it is the control of energies and forces by the animistic principle as shown in individual cases, including heredity or transmitted peculiarities, and the individual variations in growth, proliferation, nutrition, etc.

119. **Hyperpyrexia.**—A patient reported by Alexander suffered from recurrent attacks of what at first was diagnosed appendicitis, but which seemed to be associated with obstruction of the bowels. There was great abdominal distention, discoloration, stercoraceous vomiting, and a temperature which ranged, in the different attacks, as high as 112 to 113 F. Besides the fecal material, the evacuations, which sometimes were absent for a number of weeks, contained blood and pus and mucous exfoliation during the attacks. According to the patient's own statement, there had been no evacuation containing fecal material in the last two years. The patient takes three meals, but vomits a few hours after eating and has stercoraceous vomiting about every four or five weeks, greatly relieving the tension.

120.—See abstract in The Journal, xxxv, p. 1500.

121.—Ibid.

122. **Decinormal Salt Solution.**—The value of this salt solution is studied under various conditions, by Burke, who recapitulates the indications for its use under two heads, where the circulation needs filling, or when the poisons in the blood are to be diluted. Where these indications are to be met no agent will take its place. It fills the blood-vessels, and thus gives the heart something to work against. It furnishes a medium for the corpuscles to circulate in which carries nutrition to the tissues. It produces free diuresis and diaphoresis. thus liberating poisons. It delivers to the tissues two of the most essential life-giving compounds and dilutes poisons and renders them less active. It gives a respite during which we may act or in which the alarming symptoms may subside.

British Medical Journal, January 12.

Observations on Wind Exposure and Phthisis.—William Gordon.—From an analysis of the statistics of the rural districts of the county of Devon, Gordon finds that while soil has some effect on phthisis mortality if the influence of wind exposure is removed, the chief effect is entirely due to the latter. The condition of the temperature, soil or air can not account, in his opinion, for phthisis, nor can the occupation as given in the statistics of these rural districts. It seems manifest, therefore, that for St. Thomas, Newton Abbott, Okehampton, and probably Devonshire generally, the paramount influence which now determines the higher or lower rate of phthisis is the degree of exposure to or shelter from the west and southwest winds.

Jaundice in Typhoid Fever. George Ogilvie.—According to the author jaundice is hardly as rare and fatal a complication of typhoid fever as has been thought, and he reports four cases upon which he comments at length. It is a most unusual occurrence, however, that jaundice should appear at the onset of the disease and gradually disappear with the falling off of temperature and lasting through the whole course of the disease which yet has favorable terminations. In his own cases the diagnosis has been established beyond a doubt by the Widal reaction, taken with other symptoms. The relations of morbus Weilli to typhoid are discussed, and the author seems to believe that properly it is only a form of typhoid. The one case in which the agglutination failed to follow does not, he thinks, prove anything to the contrary, since the reaction was only tried once in the early stage, when it may fail also in true typhoid. As regards the pathologic condition productive of jaundice it is largely a matter of conjecture, but it seems almost certain that it is not of catarrhal nature. The rarity of catarrhal jaundice finds a natural explanation in the fact that the stomach and adjacent parts of the intestines are scarcely ever implicated in typhoid processes. Ogilvie is inclined to think that there is some direct action of specific microorganisms on the liver and bile-channels in these cases.

The Lancet, January 12.

Pneumococcic Arthritis. Edward J. Cave.—The author first reports a typical case of the acute suppurative form of pneumococcic arthritis and analyzes 31 cases from the literature in tabulated form. The majority of the cases occurred in immediate association with pneumonia (28 out of 31.) The arthritic symptoms usually followed the onset of pneumonia from a few days to a fortnight, but in two instances they are said to have preceded it. The disease is a fatal one, 25 out of 31 having died. The affection is one of adult and advanced life and far commoner in males than in females. Both these peculiarities may stand in relation to predisposing influence or previous damage to the joint. Arthritis is commonest in the lower extremities. In 19 of the cases the inflammation was confined to a single joint, and the larger joints, excepting the hip, seem more likely to be infected. In all the cases but one included in the table, the pneumococcus was demonstrated in the fluid in the joint; but similar cases have been observed in which the pus has been found sterile. It has been suggested by Widal that the pathology may be the same, but the cocci had died out at the time of examination, or the joint affection may be due to toxins produced elsewhere in the body. Another case is reported which is not included in the table, because the organism cultivated from the blood was not identified also by animal inoculation. While its culture characteristics seemed like those of pneumococci, unfortunately, owing to the pressure of professional work, it was not experimented with further before it died out. As noticed, infection is liable to attack a previously damaged joint, and the experimental observations of numerous observers show that the injection of virulent cultures of pneumococcus directly into the joint of a susceptible animal is almost invariably followed by acute suppurative arthritis. The subcutaneous injection of virulent cultures after the previous excitation of an aseptic inflammation in the joint, whether by direct injury or by injection of turpentine, gives varying results, in many instances negative (Gabbi) and in many positive. (Ausset, Zuber.) The intravenous injection of virulent cultures with associated aseptic traumatism of the joint leads to arthritis much more certainly than do injections hypodermically. Finally Bezançon and Griffon have succeeded in producing experimental pneumococcic arthritis by modifying the resistance of animals experimented on in relation to the virulence of the pneumococcus. They find in a rabbit partially immunized that a large full dose of virulent culture produces local lesions rather than general sepsis, especially in the form of pneumococcic arthritis. Leroux, who has summarized these experimental investigations, suggests the correspondence with the clinical experience that arthritis usually supervenes after a pneumonia has run its course or toward the end of an attack when the condition of greater or less immunity has been acquired. The clinical characteristic symptoms vary in severity. Fever is generally high. The prognosis is grave both as regards danger to life and the safety of the joint. Constitutional infection is liable to occur, producing its characteristic localizations in the endocardium, meninges, and other tissues. The treatment in suppurative cases, which are the majority, should be the use of asepsis, incision and flushing of the joint, drainage and fixation, as in other suppurative arthrites. The author questions whether arthrotomy for the removal of the morbid products, avoiding important ligaments and tendons would not be followed by speedier cure and better results. Convalescence is apt to be tedious and prolonged, and stiffness and adhesions remain which must be treated on general principles.

The Relation of the Bowel Lesion of Typhoid Fever to the General Symptoms of the Disease. T. J. Maclagan.—The local disturbances of the intestinal glands, according to Maclagan, are the consequence of the organic growth in the tissues of millions of the organisms produced. This would not be serious were it not for the fact that it leads to sloughing and suppuration, and these bring into play other organisms much more pathogenic than the typhoid bacillus. The existence of these organisms in the system can be determined by the prolonged duration of the fever, high temperature and other alarming symptoms, which are not due so much to direct action of the typhoid bacillus as to the various cocci associated. Gangrenous ulcers in any part of the body are apt to cause specific poisoning, and this is especially so in typhoid fever, because of the number of ulcers and consequent foci of infection. The point specially made, therefore, is that while all the symptoms of typhoid fever are traced back to an action set going by the typhoid bacilli, no one of its serious symptoms or specific dangers is due to the direct action of that bacillus.

The Practitioner, January.

The Epidemiology of Rheumatic Fever. Arthur Newsholme.—The author finds that the epidemiology of rheumatic fever is dependent especially upon dryness and lowering of the ground water. The association of dampness of the air and soil with rheumatic pain is due to the common lack of distinction between chronic and acute rheumatism, two different disorders. The organism of acute rheumatism is one which lives in the soil, but is driven out when the ground water becomes high; it multiplies rapidly in dry years and is transmitted to the human recipient in some unknown way, possibly by the dust. This is his explanation of the facts, subject, of course, to further additions to our knowledge. Perhaps bacteriology will be able in coming years to more fully explain them.

The Pathology of Rheumatic Fever. F. J. Poynton.—Poynton reviews the various theories of rheumatic fever, the nervous, toxic, chemical, infectious, and malarial theories, and gives at length a description of the cocci found by himself and Paine, to which he attributed the causation of the disease. He thinks that the diplococci are destroyed at the sites of local lesions, though their destruction usually results in some damage to the important tissues in which they have been localized. This explains the fleeting character of the symptoms in acute rheumatism. The worst manifestation of rheumatic fever is usually pericarditis, and in such cases he has obtained the most virulent cultures of the organism. The relapses that are so frequent, he thinks, can be explained by a certain form of the coccus that persists, recovering virulence if the vitality of the tissues is lowered by exposure, premature exercise, or possibly improper diet. The problems of heredity, etc., are yet to be elucidated.

Rheumatic Fever in Relation to the Throat. St. Clair Thomson.—The throat affections of rheumatism and the theory are treated of by Thomson, who summarizes our knowledge as regards throat affections as follows: 1. It is undoubted that a certain number of cases of acute rheumatism are preceded by an angina in a proportion varying from 30 to 80 per cent. 2. Both rheumatism and angina have many etiological points in common—season of year, cold, wet, fatigue, depression, vitiated air, etc. 3. The connection of angina and rheumatism, though undoubted in a number of cases, is not yet clearly established. 4. The tonsil may be the port of entry of the rheumatic virus, and this even although the naked-eye appearance of the throat gives no indication of its being affected. 5. The particular affection of the throat which is associated with rheumatism is not yet established. Apparently it is not peritonsillar abscess (quinsy). 6. Peritonsillar inflammation does not appear to be arrested by the administration of antirheumatic remedies. Many cases of parenchymatous and lacunar tonsillitis, on the contrary, are considerably benefited by the administration of salicin or salicylate of soda. That this action proves the rheumatic nature of the disease can not yet be accepted. 7. The question requires further research in two directions: one in differentiating the various forms of angina and determining the one which is associated with rheumatism; the other in further research to discover the true nature of rheumatism.

The Effects of Rheumatic Fever on the Heart. G. A. Gibson.—The author deals with the production and nature of the cardiac lesions of rheumatism, and the methods of treatment. It is highly probable, he thinks, that all cases of acute and subacute catarrhal disease are of microbic origin and therefore infective. The recent work of Poynton and Paine goes a long way to explain the connection of the microbic infection with acute rheumatism. When these organisms attack the heart it is due, he believes, to their circulation in the blood. The indications for treatment are: to avoid rheumatic implication of the heart; to enjoin absolute bodily rest, so that the work the heart is obliged to do is reduced to a minimum. He therefore holds that from the first moment of attack of acute rheumatism until some days after it has entirely ceased, the patient should be compelled to retain a horizontal position. The diet should be unstimulating, not introducing too much animal proteid matter, and it should contain abundance of fluid, so as to bathe the tissues freely. In the earlier stages of acute rheumatism the best form of diet is milk, though later a more liberal diet may be allowed. As regards drugs he believes in the use of salicylates in full doses until every symptom has disappeared, and then he begins to use absorbents, of which the most satisfactory is sodium iodid, giving 10 to 15 grs. three times a day. If there is an appearance of anemia, some iron preparation may be administered. No heart stimulants should be employed until later. Through the whole course of the disease an occasional mercurial aperient should be administered every few days. Another method which seems to him of value, is counter-irritation, though it is not easy to explain how it acts, but he is convinced of its utility.

Rheumatism in Childhood. George F. Still.—After reviewing the progress of rheumatism in childhood, Still believes that it is evident that it is very common in the later periods. During early childhood, however, rheumatic phenomena are very infrequent, and in infancy rheumatism is almost unknown. The symptoms differ from those in adults chiefly in the character of the joint manifestations and the greater prominence and frequency of heart affections. He calls attention to pains in the limbs complained of by children, the so-called growing pains, which he thinks are often evidence of rheumatism, and the practical importance of their recognition can hardly be overrated. He also mentions the frequency of affections of the hip-joint in juvenile rheumatism and the limitation of the pain to one joint for a longer time than is common in older cases. This affection of the hip-joint usually suggests commencing tubercular disease. Another symptom is the stiff neck, which seems trivial, but, like the vague pains and stiffness of the limbs, may be followed by severe cardiac involvement. The frequency of cardiac affections is also one of the most characteristic features. In 170, as far as possible consecutive, cases, 128 had cardiac bruits, which in 93 were certainly due to endocarditis. Wasting is also a more notable feature in cardiac rheumatism of childhood, and a very important manifestation of rheumatism in childhood is the rheumatic nodule. While in adults they are rare, they occur in children so frequently as to be of much importance. He found them in over half of his cases, and their close association with endocarditis is of decided clinical importance and has a bearing on the prognosis. Another symptom of rheumatism in children is sore throat. Tonsillitis is so commonly present that it is difficult to escape the conclusion that it has some direct relation, possibly as a medium of infection with the disease. Rheumatic hyperpyrexia or cerebral rheumatism is almost unknown in childhood. Among the immediate symptoms he mentions stomach pains, pain in the side, headache, and nervous symptoms, such as somnambulism, night terrors, habit spasm; another ailment several times observed associated with rheumatism in children is lienteric diarrhea, which is also a nervous phenomenon. In conclusion he mentions one further phenomenon, the association of red hair with rheumatism and heredity. He says the color of the hair may seem a small point, but it is one of the many little indications which are sometimes of value.

Presse Medicale (Paris), January 2 and 5.

Prevention of Alimentary Stasis. A. Martinet.—By reclining on the right side about half an hour after meals, and drinking in this position a cup of hot chamomile or linden tea, the contents of the stomach are rendered more fluid and their escape from the organ is accelerated by the force of gravity. In a few minutes to half an hour the patient is relieved of all the symptoms of alimentary stasis.

Dyspeptic Neurasthenia. Bardet.—Neurasthenic conditions proceeding from latent dyspepsia are common. The latter is due as a rule to excessive amounts of nitrogenous foods. This abuse keeps up hyperchlorhydria, and this in turn liberates in the blood an excessive amount of sodium. If there is hepatic insufficiency, the sodium renders the organic fluids alkaline. The first effect of the hypoacidity is usually manifest in a neurasthenic condition, and nearly all cases of pseudoneurasthenia are due to this cause. The amount of nitrogenous food ingested should be reduced to .5 or .75 gm. to the kilogram, not allowing more than 1 gm. at any time. This is sufficient to restore the acidity to normal; the same result can be attained with dilute phosphoric acid, 1 to 3 gm. a day, or even more. Bardet adds that he has never seen any serious ill effects follow its use in the hundreds of patients he has treated with it, but larger doses are somewhat laxative. Cautru has taken 100 drops of dilute phosphoric acid a day during a period of two years without inconvenience, but Weber has observed intolerance in one patient for more than 40 drops.

Quinin in Uterine Therapeutics. P. Dalche.—Quinin is useful in congestive dysmenorrhea, moderating the rush of blood to the genital regions, and is also useful in the dysmenorrhea due to neuralgia in this region, which Dalche thinks is more frequent than is generally recognized. It is possible that it might prove effective in amenorrhea, arousing the contractility of the uterus and of the utero-ovarian vessels, thus stimulating torpid ovulation. It is most effective, however, in metrorrhagia and menorrhagia not associated with any organic trouble. This dose is usually .5 to 1.5 gm. and Dalche combines it with digitalis or ergot as indicated.

January 5.

Leprosy in the Indo-Chinese Peninsula. E. Jeanselme.—The immense valley of the Irrawaddy is a focus of endemic leprosy, and an estimate of 25,000 is probably less than the actual number of lepers in the peninsula comprising Siam, Annam, etc. No organized efforts have been made to isolate them. In a large number of cases traced by Jeanselme the infection was brought into the French colonies by Chinese settlers.

Centralblatt f. Chirurgie (Leipsic), January 5 and 12.

Prevention of Shortening in Fractures of the Leg. N. Kaefer.—A plaster cast is applied to the leg and, just before it hardens, is cut in two parts by a circular incision entirely around the leg a little above or below the fracture. The two parts are then pushed gradually farther and farther apart by a mechanical contrivance which is firmly fastened to the upper and lower portions of the cast with plaster bands, and which consists of an iron rod with a screw thread at each end, winding in opposite directions and fitting into a solid female screw which forms part of a long, thin iron plate at each end. By turning a nut on the rod in the center, the two screws are forced apart. This nut is turned half or completely around every day, with no discomfort to the patient, and the fracture heals with no shortening. The apparatus is also indicated to prevent shortening after oblique osteotomy.

Resuscitation by Manual Compression of the Heart. H. Maag.—The Journal described, in its issue of July 21, 1900, p. 180, the successful experiments of Prus in the resuscitation of dogs by manual compression of the heart and blowing air into the lungs through a tracheal canula, long after apparent death from chloroform or electricity. Maag reports a case of death in chloroform narcosis after operation for nerve-stretching for rebellious sciatica. After all other attempts at resuscitation had failed, Prus' directions were followed. The heart responded promptly to the manual compressions and in half an hour the first natural respirations were perceptible. In an hour the breathing was deep and regular, the heart beating powerfully 70 times a minute, and an hour later the patient was put to bed apparently saved, although consciousness had not returned. A few minutes later respiration ceased again, and in spite of renewed efforts could not be restored. The heart continued beating for eight hours longer and then suddenly stopped, the temperature gradually falling. The air had been blown into the lungs by the mouth of an assistant.

and a large portion had found its way into the alimentary canal. This caused meteorism which forced up the diaphragm and nullified, in great degree, the efforts at artificial respiration. Prus pointed out that the diaphragm is the first to respond and take up the task of respiration. The patient was resuscitated ten to fifteen minutes after all pulse and respiration had ceased and he was cool and cyanotic. The narcosis commenced at 8; by 11:30 he was breathing regularly; by 12 all danger was apparently over, and a few minutes later respiration ceased, but the heart kept beating powerfully till 8 p.m.

January 12.

Recent Luxation of the Peroneus Tendon. H. Reerink.—A case is related in which the tendon was replaced and held in its groove by strips of adhesive plaster (Unna's zinkpflaster), and a plaster cast applied in a few days. Massage completed the cure.

Simplification of Plastic Achillotomy. O. Bayer.—Instead of the ordinary oblique division of the tendon Achilles in the treatment of spastic paralytic talipes equinus, Bayer makes the discission in two right angles facing in opposite directions, something the shape of a step. He has been very much pleased with the results attained and now states that he has succeeded in making this discission by subcutaneous tenotomy, without exposing the tendon, omitting the connecting longitudinal incision. The intact skin brings the parts into correct position. In sixteen days the patient was walking normally with both feet.

Dermatologische Zeitschrift (Berlin), December, 1900.

Lupus and Carcinoma. E. Hollaender.—In three cases, old, rebellious lupus erythematodes became complicated with multiple carcinoma, relatively benign, and all were cured by excision of the carcinomatous nodules, with no recurrence. Hollaender is inclined to attribute the etiology to the mechanical injuries of the regions affected by lupus by the repeated therapeutic measures applied.

Deutsche Med. Wochenschrift (Leipsic), January 10.

Pentose in Bacteria. E. Bendix.—An osazone has been derived from tubercle bacilli by Bendix which possesses all the characteristics of pentose, and he has established that the nucleo-proteid of the bacilli is the bearer of the pentose group. Tuberculin preparations therefore do not contain the pentose radical. Pentose was also found in a mixture of bacteria from feces, and pentosane was distinguished in some bacilli, including those of diphtheria, but never in certain others, as for instance, the typhoid bacilli.

Vaginal Incision for Tubercular Peritonitis. G. Baumgart.—More than 35 cases of tubercular peritonitis operated on by Loehlein are reported and the superior advantages of the vaginal route extolled. A number of these were described by Loehlein two years ago (*Gyn. Tagesfragen*, v., p. 99), but his example in opening the abdominal cavity through Douglas' pouch does not seem to have been followed. In some of the cases a small secondary incision was also made in the anterior abdominal wall. In the pure uncomplicated cases treated by posterior colpoceliotomy the patients were discharged in nine to twenty-two days after the operation.

Skiagraphy of the Stomach. W. Becher.—This communication states that an empty soft-rubber tube introduced into the stomach cast a distinct shadow in all the writer's skiagraphs. When he wished to fill the tube with a bismuth solution he inserted the tube first and took a skiagram and then filled the tube with the solution through a funnel. The patient stood with his back to the focus-tube.

Thymus Death. H. Kohn.—At the autopsy of a seven-months' child who had died after two days of distress and cyanosis, a very large thymus was found, compressing the aorta like a truss. The artery beneath it and the heart were very much dilated and the latter hypertrophic.

Rattle-Snake Poison in the Cure of Leprosy. J. Goldschmidt.—Dr. A. M. de Moura announced in the issue for November 29 that he had been using rattle-snake poison in the treatment of fifteen lepers at San Paulo, Brazil, and had been much encouraged by the unmistakably favorable effect of the medication. He first established the effective and safe dose by experiments on dogs and administered it internally or by subcutaneous injection. This poison has been used by the natives for a long time in the treatment of various skin affections and leprosy, and numerous instances are related of complete cure of leprosy after rattle-snake bite. Lewin makes the comment that any albumin which possesses the property of inducing irritation by a special chemical energy is able to induce such a modification of the existing conditions that marked benefit may result. No specific action is necessary. J. Goldschmidt, in the present number, describes a case of a leper bitten by a rattle-snake. He succumbed in twenty-four hours, but during this interval all the lepromata softened and subsided. A local physician attributed this effect to the methemoglobinemia caused by the poison, and treated another leper on this principle, giving him 45 gm. of potassium chlorate in sixty hours. The intoxication was very severe and nearly fatal, but on the patient's recovery a week later, the cutaneous affection was remarkably improved. Goldschmidt warns against energetic therapeutic measures in leprosy, as the patient's resisting powers are very feeble. But all the more urgently he recommends prompt and effective measures in the early, curable stages, when the lesion is restricted to the nasal mucosa or to the cheek near the nostrils. He cites cases of complete cure, including one published in the *Bull. Med.* in 1895, in which there has been no recurrence in ten years. He advises tuberculin as a differentiating measure. For local treatment he finds nothing so effective as europhen or some similar substance generating nascent iodin. Success depends on promptness and perseverance.

Importance of Indicanuria in the Pathogenesis of Certain Affections. Wolovski.—Indicanuria is the sole cause of many acute and chronic affections which are promptly cured by measures that banish the indicanuria. These conclusions are based on the study of forty-four patients, and impel Wolovski to ascribe an important place in pathology to indicanuria. In several cases of trophic cutaneous neuroses—erythema, urticaria and eczema—the indicanuria was apparently the sole cause; at least they vanished in two or three days with appropriate treatment of the excess of indican, i. e., of the putrefactive processes in the intestines. It also proved to be the sole cause in several cases of the vertigo that follows chronic overfilling of the intestines, in one case of epilepsy and in a large number of gastric disturbances accompanied by disorder of the small intestine. The absence of indicanuria in case of gastric disturbance excludes an intestinal complication and is thus a valuable differentiating measure in dubious cases. He found the most effective treatment a rectal injection of two quarts of water on retiring and the next morning calomel and jalap, 1 gram each, the patient drinking copiously of some mucilaginous fluid. Chance suggested the most effective remedy to prevent recurrence of a chronic tendency, namely, mercuric iodid, not more than 5 mg. at one dose, in keratin-coated pills, two a day. In eight to ten days the amount of indican is materially diminished. Ingestion of certain foods produces indicanuria in some persons. Wolovski describes a modification of Jaffé's test for indican in the urine which requires only thirty minutes and enables amounts of indican from one-fifth to eight times the normal quantity to be determined. He adds that it is important to note the relative amount. In two cases, one of hysteria magna, he found the amount subnormal. He uses for his test pipettes graduated to hold twenty drops to the cubic centimeter. One pipette is filled with sodium or potassium hypochlorite containing 1 per cent. active chlorin, and another with the same diluted to one-tenth, thus containing 1 per 1000 chlorin. Ten c.c. of a 25 per cent. solution of lead acetate is mixed with urine to make 100 c.c., and the whole is shaken and filtered. If the urine is very high-colored it should be diluted one-half. It must also be freed from albumin. Five narrow and tapering test-tubes holding each 5 c.c. of the colorless urine are placed in a row and to the first, one drop from pipette No. 1 is added; to the second, one drop from No. 1 and five drops from pipette No. 2; to the third, two drops from No. 1; to the fourth, two drops from No. 1 and five drops from No. 2; to the fifth, three drops from No. 1. The test tubes are turned around twice and then warmed for two minutes. Five c.c. of hydrochloric acid of 1.19 specific gravity are then added to each test-tube. They are then closed with rubber stoppers, turned around two or three times and set aside for four or five minutes until cooled. To each tube is then added 1 c.c. chloroform, and the tube is turned around ten times. If the amount of indican in the urine is normal, the depth of the tint increases to the third test-tube and then decreases until in the fifth glass the fluid is colorless. If the amount is above normal, the tint increases progressively in each glass. In this case the series of test-tubes can be carried out indefinitely until the fluid finally becomes colorless, which in some cases occurs in the fifteenth tube. If the quantity of indican is subnormal, the fluid may be almost colorless in the first tube. The amount of indican is calculated from the fact that one drop of the solution containing 1 per cent. chlorin, in pipette No. 1, corresponds to 10 cg. chlorin in one liter of urine. If, for example, 1.5 drops were used for 5 c.c. urine, out of a total of 1600 c.c., this is equivalent to 15 drops to the liter of urine and 24 drops for 1600 c.c. The quantity of chlorin varies from 20 to 30 cg. in the urine for twenty-four hours. It averages 25 cg. (making allowance of 11 per cent. for the 10 c.c. of the solution of lead acetate added). This is the absolute amount. It is much more important to determine the relative amount in comparison with the solid constituents of the urine, namely, the coefficient of indican. This is readily accomplished by the aid of Haeser's multiplying formula (2.33). For example: 1600 c.c. urine, specific gravity 1.018: multiply 18 by 2.33. This gives 42 gm. to the liter and 67 gm. to 1600 c.c. The average is 60 to 70 gm. and 6 to 7 mg. of indican, *i. e.*, 65 *gm. solid substances and* 6.5 *mg. indican.* Assuming the normal amount of chlorin to be 26 cg., we have the following proportions, 65 : .006 : .26, or the practical equivalent, 10 : .001 : .4. This can be accepted as the standard for the determination of the amount of indican. A woman excretes 40 gm. solid substances; the normal amount of chlorin in her case is 1* cg. A man excretes 90 gm. of solid substances, and for him the normal amount of chlorin is 36 cg. These are the normal amounts in these instances, although they differ widely from the average absolute amount, 26 cg.

Muenchener Med. Wochenschrift, January 1.

Treatment of Club-Foot in the Adult. O. Vulpius.—Thirty-seven patients between 13 and 35 years of age have been cured of club-foot by Vulpius, two years having elapsed in the case of 26 and four years in 15. A number of cases are described, with illustrations showing the condition before and after treatment, which was carried out without sacrificing or mutilating the bones in any way. Subcutaneous tenotomy of the tendon Achilles is always done; the plantar aponeurosis is occasionally divided, the posterior tuberosity of the calcaneum exposed and pulled down with hooks. Transplantation and shortening of the tendon were valuable aids in correcting the deformity and in two cases supramalleolar osteotomy was performed. No splints nor troughs are applied, except a night splint in congenital talipes. The success is due to "modeling correction of the deformity," kneading the foot, stretching the shortened soft parts on the concave side from the skin to the capsule of the joint, until the foot can be brought into an overcorrected position without effort and without springing back. It is not necessary to try to complete the process at one sitting, especially in adults. Each sitting concludes with the application of a plaster cast to maintain what has been accomplished. Tenotomy of the tendo Achillis is the last step. The cast is kept on between two and four months. Massage and exercises are useful in the after-treatment, but are not indispensable, as the resumption of the patient's occupation usually produces the same effect, but more slowly.

Disturbances in Sensibility of the Skin With Affections of Internal Organs. H. Haenel.—The writer of this communication has noticed certain circumscribed zones of hyperalgesia in cases of affections of the internal organs, especially with gastric disturbance. They are evidently reflex, and sugest an explanation for some of the nervous, rheumatic or hysterical symptoms of which patients complain. When found they substantiate the patient's assertions and confirm the existence of an internal affection.

Nitropropiol Test for Sugar. F. V. Gebhardt.—Nitropropiol tablets are compressed from orthonitrophenyl—propiol acid and sodium carbonate. One tablet dissolved in 10 c.c. water is an efficient test for grape sugar in urine. Ten drops of the urine added and slowly heated turn the fluid indigo blue in case sugar is present, and insoluble indigo is deposited. This reaction does not occur in the absence of sugar and is, hence, a simple, delicate and inexpensive test.

Wiener Klinische Rundschau, December 30 and January 6.

Tuberculosis Pseudoleukemica. E. Ferrari.—Sternberg was able to collect, in 1898, eighteen cases of a peculiar tuberculosis of the lymphatic system, and asserted that a large proportion of the cases assumed to be pseudoleukemia in reality belonged to this group of tubercular affections. Ferrari describes a typical case which terminated fatally in five months. When first seen the diagnosis of febrile pseudoleukemia was made, and under treatment with arsenic the enlarged glands subsided. Two months later the patient returned with acute miliary tuberculosis, which soon proved fatal. The lymph-glands and whitish foci in the organs were typical specimens of the lesions in the "peculiar tuberculosis" described by Sternberg. They were also found in the muscles, a fact never before noted.

January 6.

Tabes and Diabetes Mellitus. J. Pal.—Diabetics sometimes exhibit symptoms suggestive of incipient tabes. Pal describes a case in which the symptoms and post-mortem findings indicated that endarteritis and tabes had developed simultaneously on a foundation of syphilis, and that the endoarteritis had in turn generated diabetes mellitus. The tabes was not very pronounced, but unmistakable old tabetic lesions were found in the spinal cord.

Cure of Psychic Epilepsy by Operation. A. Pilcz.—A young man was affected periodically with mental confusion, hallucinations and generally altered character, suggesting a periodic mental affection. A linear scar above the right frontal eminence, about 4 cm. long, the result of a fall ten years before, was extremely painful on pressure. This scar was excised and the psychosis was cured. A few months later it returned in a mild form after severe alcoholic excess, and the wound was again painful. The patient has since discontinued the use of alcohol and the cure has been permanent. The case emphasizes the importance of abstention from alcohol by persons with an epileptoid tendency.

Wiener Klin. Wochenschrift, December 27 and January 3.

Extirpation of the Spleen. K. Schwarz.—In the case described, a woman of 36, in the fifth month of pregnancy, had a hypertrophic wandering spleen removed, which had caused her much suffering and inconvenience for two years. Pregnancy was not disturbed. The results were so satisfactory in this and in other cases Schwarz has collected, that he advocates extirpation for all cases of wandering spleen as the simplest and safest operation unless it is complicated by numerous adhesions. If the organ is hypertrophic, splenectomy is the only method of treatment.

January 3.

Treatment of Ulcerations With Hot Air. K. Ullmann.—The rapid and beneficial results of local hyperemia from the application of hot air in the treatment of chronic and infectious ulcerative processes have already been proclaimed by Ullmann. He now reports and illustrates a number of cases cured by his apparatus and advocates the method for venereal ulcers and all ulcerative processes, particularly of the genital tract. He has noted repeatedly a favorable influence on the general health and remote morbid foci, and describes, among others, a case of arrest and cure of a serpiginous venereal infectious process.

Books Received.

Acknowledgment of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

KINGS COLLEGE HOSPITAL CORPS; Being the Annual Report of King's College Hospital and the Medical Department of King's College. Edited by Norman Dalton, M.D., F.R.C.P., Albert Carless, M.D., F.R.C.S., John Phillips, M.A., M.D., F.R.C.P., W. D. Halliburton, M.D., F.R.S. Vol. VI. (Oct. 1, 1898-Sept. 30, 1899.) Cloth. Pp. 298. Price, 7s. 6d. London: Adlard & Son. 1900.

PHYSICAL DIAGNOSIS IN OBSTETRICS. A Guide in Antepartum, Partum, and Postpartum Examinations for the Use of Physicians and Undergraduates. By Edward A. Ayers, M.D., Professor of Obstetrics in the New York Polyclini n to the Mothers' and Babies' Hospital. loth. Pp. 283. Price, $2.00. New York: E.

INTRODUCTION TO THE STUDY OF MEDICINE. By G. H. Roger, Professor Extraordinary in the Faculty of Medicine of Paris. Authorized Translation by M. S. Gabriel, M.D. With additions by the Author. Cloth. Pp. 545. Price, $5.00. New York: D. Appleton & Co. 1901.

TRANSACTIONS OF THE WESTERN OPHTHALMOLOGICAL, OTOLOGICAL, LARYNGOLOGICAL AND RHINOLOGICAL ASSOCIATION, Oto-Laryngologic Section, at Its Fifth Annual Meeting, held at Planter's Hotel, St. Louis, April 5, 6 and 7, 1900. Paper. Pp. 48. St. Louis, Mo.: The Laryngoscope. 1900.

STUDIES FROM THE THOLOGY OF THE COLLEGE OF PHYSICIANS AND University, N. Y. Vol. VII. For the Collegi Reprints. Paper.

PROCEEDINGS OF THE AMERICAN MEDICO-PSYCHOLOGICAL ASSOCIATION, at the Fifty-sixth Annual Meeting held in Richmond, Va., May 22-25, 1900. Paper. Pp. 353. Published by the American Medico-Psychological Association. 1900.

TRANSACTIONS OF THE NORTH DAKOTA STATE MEDICAL SOCIETY for the Year 1900, and List of Members. Paper. Pp. 66. St. Paul, Minn.: St. Paul Medical Journal. 1900.

THE NINTH ANNUAL REPORT OF THE SHEPPARD AND ENOCH PRATT HOSPITAL FOR MENTAL AND NERVOUS DISEASES. Paper. Pp. 35. Baltimore, Md.: Williams & Wilkins Co.

PROCEEDINGS OF THE PATHOLOGICAL SOCIETY OF PHILADELPHIA. January, 1901. Paper. Published by the Society. 1901.

Queries and Minor Notes.

A HOME FOR PHYSICIANS.

KANSAS CITY, MO., Jan. 8, 1901.

To the Editor:—In reply to G. M. P., in issue of January 5, p. 71, concerning the establishment of a physician's home in some part of the United States, I wish to state that there is such a project, and it is meeting the encouragement of the profession at large: but a few individuals are opposing it, however. Dr. John S. Harris, of Minor Hill, Tenn., has written a few articles in favor of it, and Dr. J. O. Dyer, of Galveston, Tex., is leading the opposition.

Dr. Harris suggests that a fund be raised by subscription, and that the "home" be exclusively for physicians and their wives, who are in destitute circumstances. In my opinion, the movement will be a good one, if properly carried out; but if not conducted in a judicious and professional way, it will only amount to a failure, and a reflection on the medical profession. I beg leave to suggest, inasmuch as said "home" is to be a national affair, and that it is to be conducted under the auspices of the medical profession of America, the following:

1. That its management shall be controlled by the AMERICAN MEDICAL ASSOCIATION.
2. That it shall be called the Sanitarium and Hospital of the American Physicians and Surgeons.
3. That all regular physicians and their wives, in good moral and professional standing, shall be eligible to membership, and that no other class shall be admitted.
4. That a membership fee of $10 be charged all applicants, and that each member be required to pay $5 per annum, as dues, unless satisfactory proof be furnished that he or she is in destitute circumstances.
5. That said sanitarium and hospital shall be located in the most healthful and beautiful spot in America, regardless of all sites, and other donations offered by any individual, town, state, or corporation; so that the lives of the old veterans may be prolonged, and that their last days may be peacefully and pleasantly spent.

I am opposed to the word "home" in this sense, or to anything which will impart to it the shadow of charity. Let us be courageous, and determined to make it a sanitarium and hospital of the highest order, where members of its association can receive as good medical and surgical aid as the world affords, and enjoy all other necessary comforts of life. This can be accomplished by the proper organization and management. Fraternally, J. L. SHORT, M.D.

SHALL THE CONCEPTION OF INFLAMMATION BE ABANDONED?

CHESTER, PA., Jan. 12, 1901.

To the Editor:—In the leading editorial of THE JOURNAL for December 22. "Shall the Conception of Inflammation be Abandoned?" you refer to Andrew H. Smith's discussion of the subject. Would you kindly inform me how I can obtain the discussion of the subject by this gentleman? Respectfully,

S. B. LUCKIE, D.D.S.

ANS.—Trans. Assoc. of Americ. Phys., 1900, xv, 71-80.

KOPLIK'S SPOTS.

CANEO, TEXAS, Jan. 6, 1901.

To the Editor:—In THE JOURNAL of the 22d ult., in the proceedings of the Cleveland Medical Society, Dr. Emmett L. Holt, of New York City, makes reference to the "Koplik's sign in measles" as a valuable aid in diagnosis. Will you give me in detail what this Koplik's sign is? S. A. F.

ANS.—Koplik's sign consists in the appearance of bluish-white slightly raised spots, about the size of a flaxseed, on the mucous membrane of the inner surface of the cheeks and lips. They vary in number, sometimes only five or six, sometimes fifteen or twenty or more. They are very generally present before the other characteristic signs. These spots are figured in the last edition of Tyson's Practice, opposite p. 105. We would also refer the inquirer to the article by Dr. Koplik on "Roetheln," p. 1195, Volume xxxv, of THE JOURNAL.

RESPONSIBILITY OF MORPHINOMANIACS.

RAVENNA, OHIO, Dec. 29, 1900.

To the Editor:—Can you refer me to anything on the subject of criminal responsibility of those addicted to the morphin habit? For instance, a morphin fiend addicted to the daily use of 45 grains appropriates some property belonging to a friend or forges his name to a paper, but results in no loss to the friend. How far is such a one responsible in the eyes of the law? Would his acts be considered the same as a sane man? If you could refer me to anything on the subject you would confer a great favor on a subscriber. W. G. S.

ANS.—In Clevenger's "Medical Jurisprudence of Insanity" the subject is discussed and a number of legal citations given, showing the status of morphinomaniacs before the law. It is generally recognized in works on mental diseases that opium, like alcohol, produces conditions qualifying if not destroying criminal responsibility.

Change of Address.

Chas. Anderson, Ft. Brown, Tex., to Santa Barbara, Cal.
M. E. Arewine, Melbourne, Ky., to Williamsburg, Ohio.
J. Bruehl, New Ridge Bldg., to Altman Bldg., Kansas City, Mo.
C. Bock, Ft. Wayne, to Indiana School for Feeble-Minded Youths, Ft. Worth, Ind.
A. H. Barr, New Orleans, La., to Storkville, Miss.
L. P. H. Bahrenburg, New York City, to U. S. Marine-Hospital Service, Honolulu, H. I.
C. S. Chamberlin, Kinsman, to P. O. Box 243, Cincinnati, Ohio.
W. J. Chenowith, Chico, Cal., to Decatur, Ill.
H. Cushman, 216 Ogden Ave., to 545 Van Buren St., Chicago.
E. Cross, Del Rio, to 231 Ave. C, San Antonio, Tex.
W. C. Cole, Omaha, Neb., to 3614 Ave. C, Council Bluffs, Iowa.
U. A. D. Collelmo, Watonga, to Weatherford, O. T.

A. V. Thompson, Snowville, N. H., to Woodfords, Me.
G. H. Willis, Galien, to New Troy, Mich.
W. S. Watson, Fishkill-on-the-Hudson, N. Y., to Box 362 Salt Lake City, Utah.
M. A. Walker, Melrose, to Butte, Mont.
H. C. Wood, Irvington, to Vienna, Ga.
W. S. Whitwell, Fishkill-on-the-Hudson, to 30 W 11th St., New York City.
W. C. Welburn, 420 Woodland, to 501 Russell St., Nashville, Tenn.
C. C. Young, 348 Ogden Ave., to 231 Ashland Boul., Chicago.

New Patents.

Patents of interest to physicians, Jan. 1 and 15:

665,304. Vaginal irrigator. Moriz Bauer, Vienna, Austria-Hungary.
664,923. Atomizing apparatus. Robert L. Benson, Chicago, Ill.
664,840. Syringe. Byron J. Douds, Canton, Ohio.
665,084. Nasal inhaler. Marshall B. Gardner, Aurora, Ill.
665,243. Medical bed. Adolfo Luria, Chicago, Ill.
665,258. Liquid pasteurizer. Lars C. Nielsen and P. V. F. Petersen, Copenhagen, Denmark.
664,893. Spraying nozzle. Peter C. Peterson, Ottawa, Kan.
665,371. Syringe. Walter H. Pumphrey, New York City.
665,771. Log-holder for use in lithotomy. Willis W. Dean, Sioux City, Iowa.
665,617. Making potassium hydroxid. Heinrich Precht, Neustassfurt, Germany.
665,468. Chemical apparatus. Ralph C. Robinson, Boston, Mass.
665,756. Medicinal bath cabinet. Fortunee R. Ryan, Memphis, Tenn.
665,963. Electrolyzing soluble salts. A. J. O. Chalandre, L. J. B. A. Colas, Paris, and C. J. Gerard, Seveux, France.
665,879. Piperazin quinate and making same. Wilhelm Connstein, Charlottenberg, Germany.
666,135. Making cyanogen bromid. Carl Goepner and W. Witter, Hamburg, Germany.
666,221. Apparatus for decomposing solutions. Daniel N. Hathorne and H. E. Hobson, Rumford Falls, Maine.
666,094. Clinical thermometer. James J. Hicks, London, England.
666,210. Disinfecting apparatus. Michael Sheridan, New York City.
33,913. Design, ice or hot water bag, Christian W. Meinecke, Jersey City, N. J.

The Public Service.

Army Changes.

Movements of Army Medical Officers under orders from the Adjutant-General's Office, Washington, D. C., Jan. 10 to 16, 1901, inclusive:

George W. Adair, major and surgeon, U. S. A., member of a board at Fort Sheridan, Ill., to examine officers for promotion.

Ira A. Allen, acting asst.-surgeon, former orders amended so as to direct him to proceed from New York City, to Hot Springs, Ark., for temporary duty at the Army and Navy General Hospital at that place.

John M. Banister, major and surgeon, U. S. A., member of a board at West Point, N. Y., to examine officers for promotion.

Alfred E. Bradley, captain and asst.-surgeon, U. S. A., member of a promotion board at St. Paul, Minn.

William H. Brooks, acting asst.-surgeon, leave of absence granted.

Charles B. Byrne, major and surgeon, U. S. A., member of a promotion board at San Antonio, Tex.

Weston P. Chamberlain, lieutenant and asst.-surgeon, U. S. A., leave of absence granted.

Peter J. A. Cleary, lieut.-col., deputy surgeon-general, U. S. A., member of a promotion board at San Antonio, Tex.

Calvin DeWitt, lieut.-col., deputy surgeon-general, U. S. A., member of a promotion board at West Point, N. Y.

Franklin M. Kemp, lieutenant and asst.-surgeon, U. S. A., member of a promotion board at West Point, N. Y.

George J. Newgarden, captain and asst.-surgeon, U. S. A., sick leave of absence extended.

Maxwell S. Simpson, captain and asst.-surgeon, Philippine Cavalry, Vols., having tendered his resignation, is honorably discharged from the service of the United States, to take effect Jan. 31, 1901.

Samuel S. Turner, acting asst.-surgeon, member of a promotion board at Fort Sheridan, Ill.

Sanford H. Wadhams, lieutenant and asst.-surgeon, U. S. A., sick leave of absence from the Department of Porto Rico extended.

In addition to the above the following acting asst.-surgeons were directed to proceed from the places designated to San Francisco, Cal., for assignment to duty with troops en route to the Philippine Islands, and for subsequent service in the Division of the Philippines: James Bourke, Chicago; George J. Fanning, Sacaton, Ariz.; Almon P. Goff, Caton, N. Y.; Charles E. Jackson, Canal Fulton, Ohio; Joseph W. Love, Springfield, Mo.; Thomas C. McSwain, Bingham, S. C.; Robert C. Rogers, Bloomington, Ind.; James W. Smith, Chicago, and George B. Tuttle, St. Louis, Mo.

Navy Changes.

Changes in the Medical Corps of the Navy for the week ending Jan. 19, 1901:

Asst.-Surgeon J. B. Dennis, to delay reporting for duty at Naval Academy until Jan. 21.

Asst.-Surgeon J. C. Pryor, ordered to duty at Naval Hospital, New York.

Asst.-Surgeon R. B. Williams, detached from the navy yard, New York, and ordered to the navy yard, Pensacola.

Asst.-Surgeon T. M. Lippitt, detached from the Naval Hospital, Yokohama, Japan, and ordered to Naval Hospital, Mare Island, via *Solace*.

Asst.-Surgeon B. L. Wright, detached from the Naval Hospital, Yokohama, Japan, and ordered to Naval Hospital, Mare Island, via *Solace*.

Marine-Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the U. S. Marine-Hospital Service for the seven days ended Jan. 17, 1901:

Surgeon H. W. Sawtelle, leave of absence for thirty days granted by bureau letter of Dec. 18, 1900, revoked.

Surgeon F. W. Mead, leave of absence for sixty days from Jan. 21.

Surgeon A. H. Glennan, detailed to represent the service at meeting of Third Pan-American Congress, to be held at Havana, Cuba, Feb. 4-8.

Surgeon W. J. Pettus, granted leave of absence for two months from Feb. 5.

P. A. Surgeon J. A. Nydegger, granted leave of absence for thirty days.

P. A Surgeon A. R. Thomas, to proceed to Shields, England, for special temporary duty. Relieved from duty at Glasgow, Scotland, and assigned to duty in the office of the U. S. Consul-General at London, England.

Asst.-Surgeon C. H. Lavinder, to proceed to Vineyard Haven, Mass., and assume temporary charge of the service during absence of Surgeon F. W. Mead.

Asst.-Surgeon John McMullen, granted leave of absence for twenty-one days from Jan. 21.

A. A. Surgeon R. C. Craig, granted leave of absence for seven days.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, U. S. Marine-Hospital Service, during the week ended Jan. 19, 1901:

SMALLPOX—UNITED STATES.

California: Oakland, Dec. 29-Jan. 5, 1 case.
Connecticut: Bridgeport, Jan. 7, 3 cases.
Illinois: Cairo, Jan. 5, 8 cases; Chicago, Jan. 5-12, 19 cases.
Kansas: Wichita, Jan. 5-12, 6 cases.
Maryland: Baltimore, Jan. 5-12, 1 case.
Massachusetts: Springfield, Jan. 5-12, 1 case.
Minnesota: Dec. 29-Jan. 5, Minneapolis, 1 case; Winona, 30 cases.
New Hampshire: Manchester, Jan. 5-12, 21 cases.
New York: New York, Jan. 5-12, 17 cases, 3 deaths.
Ohio: Jan. 5-12, Ashtabula, 4 cases; Cleveland, 51 cases.
Pennsylvania: Philadelphia, Jan. 5-12, 1 death.
Tennessee: Jan. 5-12, Memphis, 8 cases; Nashville, 5 cases.
West Virginia: Wheeling, Jan. 5-12, 1 case.

SMALLPOX—FOREIGN.

Austria: Prague, Dec. 22-29, 12 cases.
Canada: New Brunswick, Port Elgin and Cape Tarmentine, Dec. 28, 40 cases.
England: Leeds, Dec. 29-Jan. 5, 1 case; London, Dec. 22-29, 1 case.
India: Bombay, Dec. 4-18, 3 deaths; Calcutta, Dec. 1-15, 81 deaths; Karachi, Dec. 2-16, 16 cases, 2 deaths; Madras, Dec. 8-14, 1 death.
Mexico: Vera Cruz, Dec. 29-Jan. 5, 4 cases, 2 deaths.
Russia: St. Petersburg, Dec. 15-22, 5 cases, 1 death.

YELLOW FEVER.

Cuba: Dec. 29-Jan 5, Havana, 5 deaths; Matanzas, 1 case.
Mexico: Vera Cruz, Dec. 29-Jan. 5, 1 case.

CHOLERA.

India: Bombay, Dec. 4-18, 6 deaths; Calcutta, Dec. 1-15, 56 deaths; Madras, Dec. 8-14, 1 death.

PLAGUE.

China: Hongkong, Nov. 24-Dec. 1, 2 deaths.
India: Bombay, Dec. 4-18, 178 deaths; Calcutta, Dec. 1-15, 39 deaths.
Turkey: Constantinople, Jan. 11, on steamship *Berrig*, from Poti.

THE TECHNIQUE OF BLOODLESS WORK.[*]

ROBERT H. M. DAWBARN, M.D.
Professor of Surgery, New York Polyclinic Medical School: Surgeon to New York City Hospital, etc.
NEW YORK CITY.

The older the surgeon, the greater becomes his respect for a drop of blood. All cutting operations on the extremities should be bloodless ones, and all elsewhere as nearly so as possible. Every drop of blood saved is a safeguard against shock; and bloodless work permits the same speed and facility of dissection that one could employ on the dead body.

At one time Petit's tourniquet, or some other, similar in principle, was the chief means for accomplishing this end. In emergency a Spanish windlass, made by loosely knotting about the limb a towel or other strong piece of cloth and then twisting a stick in it until all circulation ceases, is equally effective. Later came the use of the Esmarch rubber bandage; and until within the past few years, was for a time in regular use among surgeons. With this the blood was entirely stripped from the limb. Beginning at the foot, for example, it was carried, each turn drawn very firmly and slightly overlapping the last, up the leg, to a point well upon the thigh, where it was fastened. Then it was unwound from below up to the final turn, leaving the limb white and exsanguinated. This method is now little used. It had its advantages, but they were outweighed by certain objections. One of these is the fact that vessels subjected to such an extreme emptying and stripping process are irritated thereby. Their vasotonic nerves are temporarily paralyzed, and when the blood is again permitted to enter the limb there is distinctly more oozing from such dilated capillaries and arterioles than would otherwise be the case. Elevating the limb or the stump, and firmly pressing for an hour or longer upon the site of the wound, do to be sure minimize this oozing, but there is, nevertheless, commonly a clot formed therefrom within the wound. And all surgeons know that a wound left quite dry—cut flesh against cut flesh—always heals best and most quickly.

Again, in amputation, the operator, if he be a general practitioner, may have, become a bit rusty in his anatomical knowledge, and fail to locate the chief vessels. In the leg, we have Holden's rule: "One inch below the knee, one great artery to find; two inches, two great arteries; three inches, three great arteries." If the operator, because of their retraction, or because of a bit of fat or muscle falling over the open mouths, fails to find and control all these—and several minor ones—there is likely to be an ugly hemorrhage within a few hours. Here comes in an advantage of the present method in general use.

This consists in stripping—milking—by the fingers, for some minutes, the blood out of the elevated limb; the operator massaging along the course of the chief veins. Then, at the desired point, is applied the constriction, which is either an ordinary stout rubber bandage, or a very large rubber tube. In the former case this is ended by slipping what is left of the roll—after encircling the limb tightly a few times—beneath the final turn, the roll lying preferably over the chief vessels. Should a rubber tube be the choice, the larger in caliber the better, for it is less apt to injure the muscles and nerves beneath by its pressure; a tube of pure black gum an inch and a half in diameter, and long enough to encircle the thigh twice or thrice when unstretched is to be preferred. This is fastened very simply. We tie together the crossed ends, while still tense, with a short piece of wet bandage, using a single loop knot. Being wet it will not slip. Avoid tying a hard knot, for if the tense rubber be pricked in cutting it, the tube will be weakened and the cut be liable to enlarge and to give way when least desired. To remove, draw on the tube-ends first, thus making them once more smaller in caliber; whereupon the wet bandage loop can be untied with ease.

In consequence of the simple "milking" a small amount of blood remains in every vessel. These are not paralyzed, as is the case where the Esmarch bandage has been used, hence there is small tendency to oozing in the wound; and when the operator has any trouble in finding all the vessels, he strips sharply *down* the chief artery—the popliteal for instance—whereupon every unsecured artery and arteriole will spurt, and be located with ease.

Should the operation be one above the foot or above the hand, many operators think it best to tighten the constricting rubber bandage or tube upon the proximal limb rather than the distal, believing that because the two bones in the latter case protect the arteries between them, a greater degree of constriction is needed than if the thigh or the upper arm be chosen; and hence the leg and the forearm should be avoided for this purpose. But upon the two proximal limbs there is a choice of situations. The upper third of the thigh is so great in circumference as not to be desirable for constriction unless under compulsion, and in the lower third the external popliteal nerve lies near enough to the surface, when approaching the outer hamstring, to have occasionally been paralyzed from undue pressure. As to the arm, constriction at its middle third may paralyze the musculo-spiral nerve where it lies in its groove against the humerus. Hence, we should *select* the middle of the thigh, we should *avoid* the middle of the arm.

Our bloodless work is not wholly limited to the limbs. The scalp may, for instance, be included in this fiel by the use of a tube carried tightly about the head.

New Patents.

Patents of interest to physicians, Jan. 1 and 15:

665,304. Vaginal irrigator. Moriz Bauer, Vienna, Austria-Hungary.

664,923. Atomizing apparatus. Robert L. Benson, Chicago, Ill.

664,840. Syringe. Byron J. Douds, Canton, Ohio.

665,084. Nasal inhaler. Marshall B. Gardner, Aurora, Ill.

665,243. Medical bed. Adolfo Luria, Chicago, Ill.

665,258. Liquid pasteurizer. Lars C. Nielsen and P. V. F. Petersen, Copenhagen, Denmark.

664,893. Spraying nozzle. Peter C. Peterson, Ottawa, Kan.

665,371. Syringe. Walter H. Pumphrey, New York City.

665,771. Log-holder for use in lithotomy. Willis W. Dean, Sioux City, Iowa.

665,617. Making potassium hydroxid. Heinrich Precht, Neustassfurt, Germany.

665,468. Chemical apparatus. Ralph C. Robinson, Boston, Mass.

665,756. Medicinal bath cabinet. Fortunee R. Ryan, Memphis, Tenn.

665,963. Electrolyzing soluble salts. A. J. O. Chalandre, L. J. B. A. Colas, Paris, and C. J. Gerard, Seveux, France.

665,879. Piperazin quinate and making same. Wilhelm Connstein, Charlottenberg, Germany.

666,135. Making cyanogen bromid. Carl Goepner and W. Witter, Hamburg, Germany.

666,221. Apparatus for decomposing solutions. Daniel N. Hathorne and H. E. Hobson, Rumford Falls, Maine.

666,094. Clinical thermometer. James J. Hicks, London, England.

666,210. Disinfecting apparatus. Michael Sheridan, New York City.

33,913. Design, ice or hot water bag, Christian W. Meinecke, Jersey City, N. J.

The Public Service.

Army Changes.

Movements of Army Medical Officers under orders from the Adjutant-General's Office, Washington, D. C., Jan. 10 to 16, 1901, inclusive:

George W. Adair, major and surgeon, U. S. A., member of a board at Fort Sheridan, Ill., to examine officers for promotion.

Ira A. Allen, acting asst.-surgeon, former orders amended so as to direct him to proceed from New York City, to Hot Springs, Ark., for temporary duty at the Army and Navy General Hospital at that place.

John M. Banister, major and surgeon, U. S. A., member of a board at West Point, N. Y., to examine officers for promotion.

Alfred E. Bradley, captain and asst.-surgeon, U. S. A., member of a promotion board at St. Paul, Minn.

William H. Brooks, acting asst.-surgeon, leave of absence granted.

Charles B. Byrne, major and surgeon, U. S. A., member of a promotion board at San Antonio, Tex.

Weston P. Chamberlain, lieutenant and asst.-surgeon, U. S. A., leave of absence granted.

Peter J. A. Cleary, lieut.-col., deputy surgeon-general, U. S. A., member of a promotion board at San Antonio, Tex.

Calvin DeWitt, lieut.-col., deputy surgeon-general, U. S. A., member of a promotion board at West Point, N. Y.

Franklin M. Kemp, lieutenant and asst.-surgeon, U. S. A., member of a promotion board at West Point, N. Y.

George J. Newgarden, captain and asst.-surgeon, U. S. A., sick ler [illegible] led.

[illegible] captain and asst.-surgeon, Philippine Caval [illegible] ndered his resignation, is honorably disch [illegible] ce of the United States, to take effect Jan. 31, 1901.

Samuel S. Turner, acting asst.-surgeon, member of a promotion board at Fort Sheridan, Ill.

Sanford H. Wadhams, lieutenant and asst.-surgeon, U. S. A., sick leave of absence from the Department of Porto Rico extended.

In addition to the above the following acting asst.-surgeons were directed to proceed from the places designated to San Francisco, Cal., for assignment to duty with troops en route to the Philippine Islands, and for subsequent service in the Division of the Philippines: James Bourke, Chicago; George J. Fanning, Sacaton, Ariz.; Almon P. Goff, Caton, N. Y.; Charles E. Jackson, Canal Fulton, Ohio; Joseph W. Love, Springfield, Mo.; Thomas C. McSwain, Bingham, S. C.; Robert C. Rogers, Bloomington, Ind.; James W. Smith, Chicago, and George B. Tuttle, St. Louis, Mo.

Navy Changes.

Changes in the Medical Corps of the Navy for the week ending Jan. 19, 1901:

Asst.-Surgeon J. B. Dennis, to delay reporting for duty at Naval Academy until Jan. 21.

Asst.-Surgeon J. C. Pryor, ordered to duty at Naval Hospital, New York.

Asst.-Surgeon R. B. Williams, detached from the navy yard, New York, and ordered to the navy yard, Pensacola.

Asst.-Surgeon T. M. Lippitt, detached from the Naval Hospital, Yokohama, Japan, and ordered to Naval Hospital, Mare Island, via *Solace*.

Asst.-Surgeon B. L. Wright, detached from the Naval Hospital, Yokohama, Japan, and ordered to Naval Hospital, Mare Island, via *Solace*.

Marine-Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the U. S. Marine-Hospital Service for the seven days ended Jan. 17, 1901:

Surgeon H. W. Sawtelle, leave of absence for thirty days granted by bureau letter of Dec. 18, 1900, revoked.

Surgeon F. W. Mead, leave of absence for sixty days from Jan. 21.

Surgeon A. H. Glennan, detailed to represent the service at meeting of Third Pan-American Congress, to be held at Havana, Cuba, Feb. 4-8.

Surgeon W. J. Pettus, granted leave of absence for two months from Feb. 5.

P. A. Surgeon J. A. Nydegger, granted leave of absence for thirty days.

P. A. Surgeon A. R. Thomas, to proceed to Shields, England, for special temporary duty. Relieved from duty at Glasgow, Scotland, and assigned to duty in the office of the U. S. Consul-General at London, England.

Asst.-Surgeon C. H. Lavinder, to proceed to Vineyard Haven, Mass., and assume temporary charge of the service during absence of Surgeon F. W. Mead.

Asst.-Surgeon John McMullen, granted leave of absence for twenty-one days from Jan. 21.

A. A. Surgeon R. C. Craig, granted leave of absence for seven days.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, U. S. Marine-Hospital Service, during the week ended Jan. 19, 1901:

SMALLPOX—UNITED STATES.

California: Oakland, Dec. 29-Jan. 5, 1 case.

Connecticut: Bridgeport, Jan. 7, 3 cases.

Illinois: Cairo, Jan. 5, 8 cases; Chicago, Jan. 5-12, 19 cases.

Kansas: Wichita, Jan. 5-12, 6 cases.

Maryland: Baltimore, Jan. 5-12, 1 case.

Massachusetts: Springfield, Jan. 5-12, 1 case.

Minnesota: Dec. 29-Jan. 5, Minneapolis, 1 case; Winona, 30 cases.

New Hampshire: Manchester, Jan. 5-12, 21 cases.

New York: New York, Jan. 5-12, 17 cases, 3 deaths.

Ohio: Jan. 5-12, Ashtabula, 4 cases; Cleveland, 51 cases.

Pennsylvania: Philadelphia, Jan. 5-12, 1 death.

Tennessee: Jan. 5-12, Memphis, 8 cases; Nashville, 5 cases.

West Virginia: Wheeling, Jan. 5-12, 1 case.

SMALLPOX—FOREIGN.

Austria: Prague, Dec. 22-29, 12 cases.

Canada: New Brunswick, Port Elgin and Cape Tarmentine, Dec. 28, 40 cases.

England: Leeds, Dec. 29-Jan. 5, 1 case; London, Dec. 22-29, 1 case.

India: Bombay, Dec. 4-18, 3 deaths; Calcutta, Dec. 1-15, 81 deaths; Karachi, Dec. 2-16, 16 cases, 2 deaths; Madras, Dec. 8-14, 1 death.

Mexico: Vera Cruz, Dec. 29-Jan. 5, 4 cases, 2 deaths.

Russia: St. Petersburg, Dec. 15-22, 5 cases, 1 death.

YELLOW FEVER.

Cuba: Dec. 29-Jan 5, Havana, 5 deaths; Matanzas, 1 case.

Mexico: Vera Cruz, Dec. 29-Jan. 5, 1 case.

CHOLERA.

India: Bombay, Dec. 4-18, 6 deaths; Calcutta, Dec. 1-15, 56 deaths; Madras, Dec. 8-14, 1 death.

PLAGUE.

China: Hongkong, Nov. 24-Dec. 1, 2 deaths.

India: Bombay, Dec. 4-18, 178 deaths; Calcutta, Dec. 1-15, 39 deaths.

Turkey: Constantinople, Jan. 11, on steamship *Berrig*, from Poti.

THE TECHNIQUE OF BLOODLESS WORK.*

ROBERT H. M. DAWBARN, M.D.
Professor of Surgery, New York Polyclinic Medical School: Surgeon to New York City Hospital, etc.
NEW YORK CITY.

The older the surgeon, the greater becomes his respect for a drop of blood. All cutting operations on the extremities should be bloodless ones, and all elsewhere as nearly so as possible. Every drop of blood saved is a safeguard against shock; and bloodless work permits the same speed and facility of dissection that one could employ on the dead body.

At one time Petit's tourniquet, or some other, similar in principle, was the chief means for accomplishing this end. In emergency a Spanish windlass, made by loosely knotting about the limb a towel or other strong piece of cloth and then twisting a stick in it until all circulation ceases, is equally effective. Later came the use of the Esmarch rubber bandage; and until within the past few years, was for a time in regular use among surgeons. With this the blood was entirely stripped from the limb. Beginning at the foot, for example, it was carried, each turn drawn very firmly and slightly overlapping the last, up the leg, to a point well upon the thigh, where it was fastened. Then it was unwound from below up to the final turn, leaving the limb white and exsanguinated. This method is now little used. It had its advantages, but they were outweighed by certain objections. One of these is the fact that vessels subjected to such an extreme emptying and stripping process are irritated thereby. Their vasotonic nerves are temporarily paralyzed, and when the blood is again permitted to enter the limb there is distinctly more oozing from such dilated capillaries and arterioles than would otherwise be the case. Elevating the limb or the stump, and firmly pressing for an hour or longer upon the site of the wound, do to be sure minimize this oozing, but there is, nevertheless, commonly a clot formed therefrom within the wound. And all surgeons know that a wound left quite dry—cut flesh against cut flesh—always heals best and most quickly.

Again, in amputation, the operator, if he be a general practitioner, may have become a bit rusty in his anatomical knowledge, and fail to locate the chief vessels. In the leg, we have Holden's rule: "One inch below the knee, one great artery to find; two inches, two great arteries; three inches, three great arteries." If the operator, because of their retraction, or because of a bit of fat or muscle falling over the open mouths, fails to find and control all these—and several minor ones—there is likely to be an ugly hemorrhage within a few hours. Here comes in an advantage of the present method in general use.

This consists in stripping—milking—by the fingers, for some minutes, the blood out of the elevated limb: the operator massaging along the course of the chief veins. Then, at the desired point, is applied the constriction, which is either an ordinary stout rubber bandage, or a very large rubber tube. In the former case this is ended by slipping what is left of the roll—after encircling the limb tightly a few times—beneath the final turn, the roll lying preferably over the chief vessels. Should a rubber tube be the choice, the larger in caliber the better, for it is less apt to injure the muscles and nerves beneath by its pressure: a tube of pure black gum an inch and a half in diameter, and long enough to encircle the thigh twice or thrice when unstretched is to be preferred. This is fastened very simply. We tie together the crossed ends, while still tense, with a short piece of wet bandage, using a single loop knot. Being wet it will not slip. Avoid tying a hard knot, for if the tense rubber be pricked in cutting it, the tube will be weakened and the cut be liable to enlarge and to give way when least desired. To remove, draw on the tube-ends first, thus making them once more smaller in caliber; whereupon the wet bandage loop can be untied with ease.

In consequence of the simple "milking" a small amount of blood remains in every vessel. These are not paralyzed, as is the case where the Esmarch bandage has been used, hence there is small tendency to oozing in the wound; and when the operator has any trouble in finding all the vessels, he strips sharply *down* the chief artery—the popliteal for instance—whereupon every unsecured artery and arteriole will spurt, and be located with ease.

Should the operation be one above the foot or above the hand, many operators think it best to tighten the constricting rubber bandage or tube upon the proximal limb rather than the distal, believing that because the two bones in the latter case protect the arteries between them, a greater degree of constriction is needed than if the thigh or the upper arm be chosen; and hence the leg and the forearm should be avoided for this purpose. But upon the two proximal limbs there is a choice of situations. The upper third of the thigh is so great in circumference as not to be desirable for constriction unless under compulsion, and in the lower third the external popliteal nerve lies near enough to the surface, when approaching the outer hamstring, to have occasionally been paralyzed from undue pressure. As to the arm, constriction at its middle third may paralyze the musculo-spiral nerve where it lies in its groove against the humerus. Hence, we should *select* the middle of the thigh, we should *avoid* the middle of the arm.

Our bloodless work is not wholly limited to the limbs. The scalp may, for instance, be included in this field by the use of a tube carried tightly about the head. This rests in front in the depression between the frontal eminences and the superciliary ridges; at the sides, runs just above the ears; and behind is fastened just below the inion.

---

* Read before the N. Y. State Medical Association, Oct. 18, 1900.

Similarly, in amputation or excision of tumors of the female breast, for reasons other than malignancy, the work may be made almost bloodless by cording the breast at the body—first passing through its base crosswise a pair of long mattress needles, to insure against the tube slipping off.

About the bladder, perineum and genitals, both male and female, Trendelenburg's posture secures by gravity a degree of anemia which constitutes a great safeguard, in addition to other advantages resulting from this position. And in work about the face and mouth, and upper part of the neck—a peculiarly bloody field—a ligation of one or both linguals, if a tongue excision, or of the external carotids in other cases, makes a wonderful difference in the ease and safety of the work.

The production of a degree of anemia of the trunk and head by cording of the extremities, was a suggestion of Dr. David Webster, in the *New York Medical Journal,* during 1887, his idea being to make use of this plan for the safety of the patient when the operator has reason to fear collapse from the anesthetic. At first the constricting bands are only placed tightly enough to cause the limbs to swell; and then the arterial flow is also shut off. Some quarts are thus accumulated in the extremities, maintaining a reserve guard of pure blood. And if during the operation the patient suddenly develops signs of excessive narcosis, by removing the bands and holding up the limbs the pure blood at once is mingled with the anesthetized, and almost instantly the patient wakes up. The method is little used, but is certainly ingenious.

This same idea, of constricting the extremities, enables one to do comparatively bloodless surgical work on the trunk, face, neck or brain, and is worthy of more frequent usage than at present. It is also unquestionably the best, indeed the only reliable, method of treating medical—as distinct from surgical—hemorrhage. By a medical hemorrhage, I mean one where direct mechanical control is out of the question: hemoptysis, hematemesis, and apoplexy, for example. It is a curious fact that this best of all methods—and a very old one—has been completely lost sight of by most practitioners.

Some years ago I wrote a paper[1] entitled "Medical Hemorrhage Surgically Treated," and therein discussed this matter. At that time Dr. William Gilman Thompson wrote me that he entirely agreed with me that it was the most reliable way of treating ugly hemoptysis, that he had so found it in his service in the New York Hospital. Nevertheless, Loomis' "Practice" does not even indicate by so much as a word that he ever heard of the method, nor do I now remember any other work upon practice which discusses it.

As to drugs, Dr. Loomis was a pessimist. He advised the use of morphin, simply to quiet the patient and slow the breathing; but nothing else did he think of much value for this purpose, except aconite, if the heart were pumping too vigorously. We know that one of the old names for aconite—besides monkshood and wolfsbane—is "the vegetable lancet"—bleeding a patient into his own veins.

What aconite can do in a very feeble and slow way, cording the extremities does effectively and promptly. Three limbs should be so corded close to the trunk that they swell visibly. This swelling continues until, from cardiac and brain anemia, the patient is made somewhat faint—and consequently there is less vigorous pumping of blood out of broken vessels, and there is a better chance for a firm clot to form there, opposing fresh bleeding when, after two or three hours, the circulation is slowly allowed to resume its ordinary course. The reason three limbs, not four, are to be corded, is to insure their safety. After a half-hour we cord the fourth limb and let up on the first one, and so on in regular order.

A recent sensational murder in politics, in another state, produced a bit of most antiquated and archaic surgery—according to the newspapers and several medical journals, and the statement went uncontradicted. I allude to the fact that in order to try to stop the bleeding from his wounded lung the surgeon bled him a pint or more from his arm! This plan has antiquity to recommend it, but nothing else. He died of shock, apparently, and we all know that hemorrhage invites shock. Had the extremities promptly been corded effectively, accumulating venous blood in them, the ending might well have been a different one.

Obviously, the same method is the proper one in apoplexy, in which there is a ruddy face, hard pulse and stertorous breathing. If the patient is plethoric, bleeding is best, but not otherwise, for he would need that blood later on. A temporary bleeding, into his own vessels, is the thing.

Given a case in which atheromatous vessels, too much eating and drinking, and occasional attacks of dizziness or semi-unconsciousness point toward the probable ending of the story, we should tell the relatives that if this patient should ever be found unconscious and snoring, with a red face, the first thing to do should be to apply Spanish windlasses, even before sending for the doctor; and they should be shown how to make and use them. In this way what might otherwise prove a fatal apoplexy would very likely be reduced to a comparatively small one.

Applying the bloodless method to the surgery of acute injuries, let me discuss for a minute a plan which I got many years ago from Dr. Gerster. Suppose we are dealing with a fresh but obscure injury at the elbow. It may be a fracture, or a dislocation, or both. Because of the swelling an exact diagnosis is impossible; and yet the doctor's reputation may in that case well depend on his accurate diagnosis—for on that alone can his treatment be based. If you wrap the elbow of a skeleton in a pillow and then endeavor to recognize the bony prominences through it, you will approximate the situation. Here comes the point in question, which I have used with satisfaction repeatedly. Anesthetize the patient; then apply the rubber bandage, slowly but firmly, from fingers to shoulder. Leave it on for, say, fifteen to twenty minutes; then undo it from below, but leave the final turn or two in place. Upon examining the elbow the swelling will be found to have disappeared, all the congestion and all the edema being gone; and you can recognize all bony points as accurately as upon the other arm. If there is a fracture, set it; if a dislocation, reduce it; then let the swelling return. You know the facts, can state the probable prognosis, and have protected your reputation.

Time only permits a momentary allusion to certain additional interesting fields which could properly be studied under the head now being discussed. In snakebites, for instance, perhaps the most important point (next to venom antitoxin), is to make a free incision at the bite, and, having corded the extremity high up, milk out every drop of blood, from both directions—preferably with the rubber bandage—stripping toward the cut in both instances. And then fight the enemy in detachments. That is, when the patient is a little stronger let up on the tourniquet a moment, thus admitting a little blood to keep alive the limb, and also inevitably giving entrance into the general circulation to a little of the poison which presumably still remains in spite of the stripping. When the heart has withstood the shock of this, again fight another small squad of the enemy by letting up a moment, and so on.

---

[1] N. Y. Medical Record, Jan. 2, 1892.

We are all interested in tonsillotomy, and all do it *at times*. I should like very much to have you try the bloodless method, on which I have written two or three papers.[2] Done *before* the cutting, and by aid of eucain, it is easy to pass, with a stout semicircular needle and holder, the purse-string suture as advocated by the writer; and, after tightening this, the biggest and ugliest tonsillar stump can not bleed a drop when severed. I have heard it said that the method must be difficult of accomplishment, but those who said so have not tried it. It is in adults, chiefly, that tonsillar hemorrhage is dangerous, and nothing can be simpler than this plan, used upon the adult. I believe that it will come into regular use in time.

Under eucain the vessels are not contracted at all—a good point in tonsillotomy, because cocain so shrinks the mass, temporarily, that it is difficult not to leave a large stump, which protrudes after the effect of the drug has worn off. But this power of cocain—and to an even greater degree and a somewhat more lasting one, that of suprarenal extract—is of the utmost value *prior* to certain operations, for example, within the nose. It is a good plan to use the suprarenal extract first; and when the mucous membrane has become pale, almost bloodless, then cocain in almost any strength can be safely applied, and the operation will be devoid of hemorrhage.

Similarly, solutions of suprarenal extract and of cocain are of great advantage when applied by aid of wet gauze packed into the rectum, vagina, or bladder before cutting for the removal of growths, or for other purposes, in these vascular fields.

I regret that bloodless work as applied to *starving* malignant growths supplied by the external carotids can not be studied to-day. It is too large a topic. But it may interest you to know that the writer has now cut out the entire external carotid more than thirty times in the past five years, and it has also been done by Drs. Keen and Da Costa, in Philadelphia, by Drs. Brewer, Blake, W. Meyer, and Lilienthal, in New York, and by Dr. Nicolson, in Atlanta, Ga.; and from all these instances only three or four deaths have resulted from the operation, these being all in cachectic patients suffering from malignant growths—a rather unexpectedly low mortality. The operation, to be of use, must be performed on both sides, but not at one sitting, of course. And merely *ligating* upon both sides is quite useless, for within a few days pulsation will return from outside sources by anastomosis. It is the more radical measure of complete double *excision* which I am here discussing.

When the writer's paper on this topic was read before the New York Surgical Society, last spring, five patients were shown with starved and shrunken malignant growths—cancers and sarcomata—one of which dated back about five and a half, and one four years. It really seems to offer, as a method, when performed upon both sides, a clear ray of hope to the otherwise hopeless; for nothing can be more pathetic and desolate than the outlook for a patient with cancer of the tongue or floor of the mouth, for example, which has advanced beyond reach of the knife.

105 W. 74th Street.

ANALGESIA FROM SPINAL SUBARACHNOIDEAN COCAINIZATION.*

JOHN B. MURPHY, M.D.

CHICAGO.

Since the anouncement of the first death from chloroform anesthesia the medical profession has been constantly looking for an anesthetic that might be administered without danger. Ether then was reinstated and heralded as a drug without danger, when given as an anesthetic. Shortly after its adoption several deaths occurred which were attributed to its use, and the mortality has been constantly increasing, especially within the last five years.

The combination of ether, alcohol and chloroform was submitted to the profession as a substitute for the individual drugs and the claim made that the danger would be less. The various mixtures, however, have met the same fate as the separate ingredients.

Nitrous oxid, the oldest of the general anesthetics, was again advanced, as was also ethyl bromid, but both were found impracticable, except for very short operations. Each of the anesthetics mentioned above has its special field wherein it may be used with less danger than any of the others, none of them answering the requirements for the performance of all surgical operations.

Local analgesia was used long before the general. The various means of producing it are: 1, by rendering the tissues ischemic; 2, frigid analgesia, being produced by ice and the various sprays; 3, nerve pressure analgesia; 4, dermal and subdermal analgesias—by the injections of solutions of cocain, eucain, nirvanin, etc.; 5, tissue-infiltration analgesia—as Schleich's and its modifications; 6, local application to mucous membranes of cocain, eucain, etc.; 7, injections of the various local anesthetics into the nerve trunks supplying the field of operation, and finally, 8, subarachnoidean spinal analgesia.

To-day we are to consider from a theoretical, as well as a practical standpoint, the last-named method, with the meager data now at our command.

Dr. J. Leonard Corning, in 1884 and 1885, demonstrated that analgesia could be produced by the submeningeal injection of cocain into the spinal canal. He also suggested a method of treatment for painful diseases of the spinal cord by this means, but the surgical application was not considered by him.

Bier, Aug. 16, 1898, demonstrated that analgesia of the extremities for surgical purposes could be produced by this means. He performed his first operation, a resection of a tubercular foot, by using 3 cubic centimeters of a .5 per cent. solution, containing 1/4 grain of cocain. Following this he performed, within one week, six other operations by the same method. In one of his cases the analgesia involved the entire body, excepting the head and upper portion of the neck. This case was that of a boy 14 years of age; 7½ minims of a 1 per cent. solution, equivalent to 1/12 grain of cocain, was used. August 24, eight days after using it on the first patient, Bier decided to have the effects of the drug studied upon himself, and he was accordingly given an injection. The needle was inserted into the spinal canal, but did not accurately fit the syringe barrel, so that a considerable quantity of the cerebrospinal fluid was lost and a very indefinite amount of cocain was injected. There was no analgesic effect produced, but he suffered from severe cephalalgia, some nausea, considerable vertigo, etc., which symptoms persisted for nine days. Whether the unpleasant effects were due to the amount injected or to the loss of a large quantity of the cerebrospinal fluid, it is, of course, impossible to state. His associate, Dr. Hildebrand, was given a full injection of one-sixth of 1 grain the same day, and with him the analgesia was perfect and there were no untoward symptoms.

---

[2] N. Y. Medical Record, Dec. 17, 1892; N. Y. Medical News, May 20 and June 10, 1899.

* Read before the Western Surgical and Gynecological Association, Minneapolis, Dec. 27-28, 1900.

Bier concluded, notwithstanding the unsatisfactory result obtained on himself, that this mode of producing analgesia was applicable to a wide range of surgical procedures involving the extremities, and further, that it should be administered with extreme caution, the greatest care being exercised in the preparation of the solution, the syringe and the back of the patient. He further advocated that local analgesia of the tract of the needle be first produced.

Up to the present time there has been no great deviation from the technique outlined by Bier, excepting the range of dosage and the substitution of other materials for the cocain, as eucain, nirvanin, antipyrin, etc.

While the results of Bier were not very flattering, it encouraged others to take up this line of investigation, the most conspicuous in the field being Tuffier. The number of investigators has since become so large that to-day with only a moderate effort I am able to present 631 operations under spinal analgesia. The names of the operators are given in alphabetical order, without reference to priority, as in this way they are more accessible for reference. The successful cases will not be considered in detail. Of the 631 cases here reported perfect analgesia was obtained in 94, or 45 per cent; partial in 2.21 per cent., and in 3.32 per cent. it was a total failure. Of the deaths which were reported to have occurred as a result of this method, I fail to find one directly attributable to the cocain. Of those which occurred in Tuffier's clinic, in only one was it possible to associate death with the injection, and in that case marked cardiac lesions were found post-mortem. This one death has been reported in a number of articles as directly due to the cocain, but a close analysis of the details shows there is good ground for believing that the drug was in no way responsible for it.

M. Racoviceanu Pitesci, of Bucharest, states that he heard of two deaths from spinal injection occurring in Roumania, but he says they were not in his practice and as he fails to give the details, I have not included them in my list. In three of the 125 injections given in Pitesci's clinic the symptoms were spoken of as dangerous; but in none did they terminate fatally.

We will now consider: 1, the physiologic effect of the injection; 2, the dosage; 3, the rapidity of injection; 4, the constant and occasional symptoms produced; 5, the analgesia following, and 6, post-operative symptoms.

1. *The Physiologic Effect.*—Corning recognized the affinity of cocain for the sensory nerve fibers and therefore reasoned that the application of the drug to the spinal cord would produce analgesia over the area supplied by the spinal nerves so treated. That the effect is produced by the direct application of the cocain to the posterior roots and ganglia and not to the cord itself, is supported by the clinical observation that in a number of cases the analgesia is an ascending one, taking place in the trunk and neck before it has appeared in the extremities. If it were a sensory tract paralysis it should occur in the lower extremities first. The sense of contact is not affected; the reflexes are slightly altered—usually diminished; muscular sense and co-ordination are often affected, as after the injections the patients have considerable ataxia of gait; intestinal peristalsis and uterine contractions are rather stimulated then depressed, while sphincteric action of bladder, vagina and rectum are often completely abolished. The increased peristalsis, with sphincteric relaxation, accounts for the frequent defecations and less frequent urinations which take place during the course of the anesthesia. The above leads to the speculation: Can not reflex ileus be treated by this means?

2. *Dosage.*—The great majority of operators at the present time, who have adopted cocain analgesia, agree that the 2 per cent. solution is preferable, except in younger patients, where the 1 per cent., as advocated by Bainbridge, should be used. They also agree that the quantity of 2 per cent. solution injected should range from 7 to 20 minims in the adult, depending on the individual peculiarities of the patient, the location and probable duration of the operation, etc. Ten to 15 minims is the average amount required, it being seldom necessary to use more than 15, and except in hemorrhoidal and vaginal operations, less than 10. Tuffier has used 2/3 grain without unpleasant symptoms.

The method of preparation of the solution is of great importance, as cocain is a very unstable drug when in solution and exposed to the air. It will not tolerate boiling for sterilization. The solution should, of course, be freshly prepared at the time of operation, by adding sterile water to a definite quantity of the crystals, weighed amounts of which may be previously sterilized in waxed papers and kept ready for use. An excellent method is as follows: A strong solution of the hydrochlorate of cocain is prepared in distilled water, so that a certain amount will represent 3/10 of a grain. This is placed in sterilized glass tubes and the water evaporated in vacuo. The dried crystals left by evaporation are sterilized at a temperature of 180 F. and the tube sealed in the flame. A file-mark is placed at the top of the tube where it is to be broken off when ready for use and another file-mark represents the level to which exactly 15 minims of water will come. At the time of operation the top of the tube is broken off and cold sterile water added to the second file-mark, making exactly 15 minims of a 2 per cent. solution.

Glass ampullæ containing the solution have been prepared by certain manufacturers, by placing the crystals in sterile water, rapidly heating the solution a number of times to 180 F., and then sealing the tube. Last week we used one of these tubes that had been prepared four months previously by a Chicago instrument house. The result was ideal, showing the length of time which cocain may remain in solution without decomposition when kept in a sealed tube. If the solution is the least cloudy the cocain will be found to have decomposed. It can not be too strongly emphasized that the solution should be sterile to be free from danger.

The ordinary hypodermic syringe with a sliding attachment and the 3-inch needle, the latter having a lumen of 8/10 mm. and an external diameter of 1.1 mm. may be used. Special cases containing all the necessary instruments, etc., are now prepared by manufacturers. The syringe must be made of material that will permit of boiling the entire instrument. The quantity of solution drawn into the syringe should exceed that which is to be used, as some may be needed to free the needle from blood in case there is difficulty in entering the canal. The set-screw governing the quantity should be placed before connection with the needle is made.

Before inserting the needle the skin may be frozen with ethyl chlorid and a puncture made with a scalpel, so that no infection might be carried from the skin along the tract of the needle. It is our custom to fill the needle with cocain solution before it is inserted, thus preventing the admission of blood into the lumen in transit through the tissues of the back.

The space between the fourth and fifth lumbar vertebræ ½ inch to the side of the median line is the point of election. In this position it will be seen that we are some distance below the conus medullaris and directly over the cauda equina. The patient is placed in a sitting position with the limbs extended on the table and the back curved as far forward as possible. Standing at the patient's left, the thumb is placed over the fourth lumbar process so that its tip extends 1/3 inch below the spinous process and the same distance to the right of the median line. The needle is then passed in, in a horizontal direction, just at the tip of the thumb. Occasionally the bone is encountered, when it will be necessary to change the direction of the needle downward. When the needle reaches the interspinous ligament there is a little additional resistance, which is suddenly overcome when it penetrates through that and into the spinal canal, this latter being demonstrated by the escape of cerebrospinal fluid. If the fluid does not escape the patient should be requested to strain or cough, which will often cause it to be forcibly ejected. In one case of deformed back and pelvis it was impossible for us to insert the needle into the canal. Dr. E. H. Lee had a similar experience, as did also Dr. La Place.

Tait and Caglieri, of San Francisco, have in three cases injected cocain solution into the subarachnoidean space between the sixth and seventh cervical vertebræ. Their results were good and they believe that there is no danger of traumatism to the cord in this situation, but the experiments of Masso and Aducco, who injected solutions of cocain into the fourth ventricle in certain of the lower animals showed that this procedure was invariably followed by almost immediate death, due to respiratory and cardiac failure.

These experiments argue against the safety of the high injections, which should certainly not be used until after thorough and careful investigation has been made.

3. *Rapidity of Injection.*—The fluid should be injected slowly, from forty to sixty seconds being consumed in the procedure. Goffe states that when the injection is sudden and forcible the analgesia will extend higher than when it is slowly given. This statement is denied by Marx. The solution should never be injected except when the cerebrospinal fluid is flowing from the needle. We do not consider it good practice to repeat the injection immediately or soon after in the same patient, although Marx has carried the analgesia for eight hours by repeated injections and has observed no untoward symptoms. His cases were all obstetric. If it is desired to continue the analgesia, a small quantity of chloroform or ether may be administered.

4. *Symptoms Produced by the Injection.*—One of the first to appear is a sense of heat passing over the entire body, and later thirst. From three to fifteen minutes after the injection, most frequently seven to eight, nausea and one or two attempts at vomiting occur. Sometimes the nausea continues for ten minutes, and there may be several efforts at emesis. Preceding the vomiting there is the usual pallor, increased frequency of the pulse, which, however, may be very slow, diminution of arterial tension and perspiration. In other words, we have all the symptoms which ordinarily accompany nausea from any reflex cause. Perspiration may be very profuse, as it is in all cases of cocain intoxication, but the same symptom has been noted after the injection of saline solution into the subarachnoidean space. The pulse may become scarcely perceptible at the wrist and the facial expression is often that of profound depression. These untoward symptoms usually last but a few minutes and then disappear. In several cases that have been reported, the symptom of collapse, which occurred a short time after injection, was very alarming. McDonald records one where the respiration went up to 60 or 80 a minute, cyanosis was marked and the patient became almost pulseless. Large doses of stimulants were necessary to revive him. We have noted in a number of cases that the more severe the operation the more rapidly have the symptoms of depression, due to the cocain, disappeared.

The capillary circulation, as a rule, remains good, even when the arterial tension is very low. Respiration has not been materially affected in any of our cases, but several authors have reported it as sighing in character. As stated above, McDonald observed a case where the respirations were increased to 60 or 80 per minute, with marked cyanosis.

The sphincter ani is frequently relaxed, even to the extent of allowing involuntary evacuations on the table. Occasionally the vesical sphincter is relaxed. The relaxation of the vagina and rectum, which is so common in cocain analgesia, would theoretically be of advantage in obstetric cases.

Various drugs, given hypodermically, have been recommended to counteract toxic symptoms, but probably the best are hyoscin hydrobromate, 1/200 grain, injected immediately after the cocain is administered, and nitroglycerin, 1/100 grain, given at the same time, or when nausea and vomiting first appear—Marx.

5. *The Analgesia.*—This first appears in from three to ten minutes after the injection, though it may be delayed to twenty, or even thirty minutes. Sometimes it is preceded by a short period of hyperesthesia involving different parts of the body.—Marx.

The analgesia almost always commences in the feet, but in rare instances is first noted as a band around the body extending downward on the fronts of the thighs. Still more rarely the analgesia is ascending from the level of injection, involving the thorax, the upper extremities, neck, face, and occasionally reaching to the scalp. It can be estimated that the analgesia will be perfect up to the costal arch and will involve all of the abdominal viscera. Amputations of the breast have been performed without pain, but the upper limit of the analgesic area rarely extends high enough for the performance of this operation.

The analgesia may be complete, partial, or entirely absent. Its duration is from twelve minutes to three hours, or even more. In one of Marx' cases it persisted five hours, but the average in our experience has been from twenty-seven minutes to one and one-half hours. During this period, particularly when the operation is a laparotomy, the tension of the muscles sometimes interferes with work, though not to a sufficient degree to seriously impede the continuance of the most difficult operation.

At first the use of the drug in spinal analgesia was *confined to persons in middle life, but since then it has* been clearly demonstrated that it may be administered with safety to patients of all ages, from infancy (Bainbridge, New York) to old age (Lyman, Eau Claire).

6. *Post-Operative Symptoms.*—When the operation has been completed and the patient returned to his room he usually complains of headache, which is sometimes very severe and lasts for several days, but the rule is that it subsides in from twelve to twenty-four hours. We have not observed emesis after the patient was removed from the table, but prolonged nausea and vomiting have been reported. (Barbat, two cases; McMonagle.)

Vertigo is occasionally present and sometimes a marked ataxia in gait. In rare cases the ataxia has extended to the upper extremities. It is extremely annoying to the patient and may persist five or six days.

The pulse, which may have been very rapid and weak during the course of the operation, soon returns to normal. Temperature usually occurs the evening following the injection. It is often preceded by a chilly sensation, rarely by a rigor. It may reach 104 F., or even 106.8 F.—Fowler. In our experience it has ranged from 99.5 to 102 F. The temperature is a spinal one and not in any way connected with the wound. It is probably due to irritation of the thermic center in the cervical portion of the cord, resembling, as regards its causation, the marked thermic elevation seen in spinal traumatism. The rule is that it disappears entirely by the following morning and does not recur, though in some instances it has been observed to persist three or four days.

The patient's general condition on the following day, even in laparotomies and other major operations, has been uniformly better than when ether or chloroform was used, and the tissue reaction to the traumatism has been less marked.

Various mental disturbances have been reported by different authors to have followed spinal injections of cocain. In the case reported by McDonald, previously cited, coma occurred; Hartmann and Fowler have both noted delirium. Exhaustion and prostration lasting one or two days have been reported by Severeanu, of Bucharest. The mental exaltation which so frequently follows use of cocain is often observed.

Stiffness of the neck and muscles of the back, various disturbances of vision, tonic contractions of different sets of muscles, pains along the spine, loss of heat and cold sensation in the analgesic parts, etc., have all been noted during the post-analgesic period.

Most of these symptoms also occur after spinal injections of eucain, which would lead us to believe that they are due to variations of tension in the spinal canal, or to irritation, rather than to the toxic effects of the drugs.

Goldan reports that he has observed pneumonia following spinal injections, due to the exposure from which the patient suffers while being prepared for the injection, and exposure during the operation. He argues from this that the so-called ether pneumonias are not always due to ether, but rather to the bodily exposure *during the preparation for the operation.*

7. *Failure to Obtain Analgesia.*—We will quote the statements of a number of operators as to the causes of failure:

Bogart believes that his 28 per cent. of failures were explainable by faulty technique or selection of cases. Irregularity in the action of the drug in different cases and at different times in the same case is beautifully illustrated in one reported by Bergmann, where acute cocainism followed a very small injection of the drug several days after a much larger dose had been given without untoward symptoms. Cartledge, of Louisville, had no failures in his cases and states that many of his patients were in better condition at the end of the operation than if other anesthetics had been used. Fowler had three failures, all of which were due to his inability to secure free flow of cerebrospinal fluid. He either obtained none at all or only a small quantity of very turbid fluid.

Goldan attributes three of his failures to a too large needle or a too small quantity of solution injected, but in a later paper he reports three additional failures for which he was unable to satisfactorily account. Matas attributes too small a dose as the cause of failure.

The uniformly good results of some operators contrast strongly with the uniformly bad results of others. The former is represented by the ideal experience of Morton, San Francisco, who in 31 cases had perfect analgesia in all and no serious untoward effects. The other class, larger in number, is composed of operators who have had a small number of cases in which the percentage of failures has ranged from 7 to 100. This great difference in results I can but believe is due to variations in technique.

Chronic alcoholics seem to be unfavorably affected by the drug, in some a failure of analgesia occurred—Coelho—and in others there was pronounced intoxication—McDonald.

The idiosyncrasy to cocain is more frequent than to any other drug and has been cited to explain the absence of analgesia noted by many authors—Racoviceanu Petesci, Alessiu, Pousson, Chavanaz and Coelho. The same reason has been given for the severe intoxication observed.

Substitutes for cocain in spinal analgesia are: 1. Eucain B was used in our fifth case, with only a partial analgesic effect. The solution was 2.5 per cent. Keen reports one case of perfect analgesia in which he used 1 c.c. of a 2 per cent. solution. The general opinion is that eucain can in no way take the place of cocain in this work, but certain authors advocate and use it exclusively. The unpleasant symptoms are usually the same as when cocain is used and the analgesia not nearly so satisfactory—Engelman. 2. Antipyrin was used in one case by Fowler, who injected 30 minims of a 2 per cent. solution; analgesia occurred to the level with the nipple in five minutes. All of the disagreeable symptoms were present, but were later in manifesting themselves than when cocain was used. Weber, of Chicago, uses a weak solution of antipyrin in combination with cocain. Combination of cocain and morphin has been used—Schleich's solution—by Matas, without, however, any marked change in the result. Marx observed in one case intoxication after using 1/6 grain of morphin in combination with the cocain.

One case of death is reported from pulmonary embolism nine days after the operation. It is not stated that the cause of death was verified by post-mortem examination.

Gumprecht's statistics of 17 deaths from lumbar puncture performed for diagnostic purposes in the presence of severe cerebrospinal lesions, have no value in guiding us as to the practicability of cocain analgesia.

The persistent false statements in regard to Tuffier's deaths would be amusing if it were not that they so outrageously falsified his experience.

RHEUMATIC DISEASES OF THE EYE.

H. W. WOODRUFF, M.D.

Professor of Ophthalmology in the Chicago Eye, Ear, Nose and Throat College, and Surgeon at the Illinois Charitable Eye and Ear Infirmary.

JOLIET, ILL.

That the eye should be subject to rheumatic disease does not seem strange when we remember that its principal protective coat is a dense fibrous structure, the sclerotic; that it contains within it the delicate muscular fibers of the iris and ciliary body, and externally the muscular bands which move it about; that it is very vascular, one coat alone, the choroid, being largely made up of blood-vessels. The wonder is that the eye does not suffer more from a disease as prevalent as rheumatism and one which shows such a predilection for fibrous, muscular, and vascular structures.

It is not the object of this paper to discuss the subject of rheumatism in general. Suffice it to say that many observers believe it to be, like gout, caused by uric acid, a product of inefficient proteid metabolism; others by lactic acid, a fermentation product of the hydrocarbons. The researches of Singer, Achalme, Thirolox and Schüler would lead us to consider it to be a microbic disease. Reinhard believes the throat to be the common infection atrium.

Neither the eyeball nor its appendages are often affected by articular rheumatism. Iritis rarely occurs with it, but cases of conjunctival congestion without mucopurulent discharge have been noticed. We are compelled, however, to recognize the use of the term "rheumatism" as applied to an extensive group of symptoms which are probably dependent on the same causes with articular rheumatism. Sudden exposure to cold and overmuscular exertion are the principal exciting causes. Some of the diseases of the eye ascribed to the chronic type of rheumatism are iritis, episcleritis, scleritis, keratitis, orbital cellulitis, optic neuritis, choroiditis, ocular palsy, glaucoma, and opacity of the vitreous. The most important of these in point of frequency is iritis.

It has been computed by various writers of authority that iritis furnishes from 2.3 to 4 per cent. of all ophthalmic cases, and that syphilis and rheumatism are causative factors of this disease in 90 per cent. in the proportion of syphilis 60 and rheumatism 30. It was formerly taught that the etiology of iritis could be determined by simple inspection, and it is true that in many cases the papules or condylomata characteristic of syphilitic iritis can be made out.

In the absence of these masses in the iris, however, the diagnosis depends on the history of the individual case. In the absence of a syphilitic history or signs, we may find a personal or family history of acute or chronic articular rheumatism, symptoms of lumbago, neuralgia, sciatica, torticollis or pains in the articulations or fascia or sensitiveness to changes in the weather. Many cases are subject to relapses of iritis in spring and winter, seasons of the year when rheumatic affections are most prevalent. Some cases of iritis alternate with rheumatism in other parts and some recur with the swelling of the joints.

I will briefly report three cases representing, respectively, iritis, episcleritis, and scleritis of undoubted rheumatic origin.

A woman, aged 25, came to the clinic at the Illinois Eye and Ear Infirmary, in February, 1899. She gave a history of chronic articular rheumatism. Her father was a chronic rheumatic. A diagnosis of rheumatic iritis was made. There was present the typical sign of iritis: ciliary injection, pain in the temple, slight adhesions of the iris to the lens capsule, which yielded to atropin. No nodules were present in the iris. No history nor signs of syphilis, either inherited or acquired were evident.

The patient made a rapid recovery under salicylates internally and atropin in the eye and hot applications. She was free from trouble until last April, when she presented herself again after having suffered pain in the eye for two weeks. The same treatment was continued and improvement again occurred until the early part of this month, then, with a sudden change in the weather, came a relapse of the rheumatism and also a violent pain in the eye. This gradually yielded to hot baths and pilocarpin and leeches applied to the temple; but the exudate from the iris was more abundant and plastic, and adhesions more numerous and permanent.

Next in frequency occurs a superficial form of scleritis, episcleritis, which consists of a circumscribed inflammatory nodule, generally on the temporal side. It is not movable over the sclera, but firmly attached and of a reddish-violet color. This condition can never be looked on as merely a local disease, but must be regarded as the manifestation in the eye of some systemic derangement. The large percentage, if not all of them, are associated with the rheumatic diathesis.

A case illustrating this condition was recently under treatment at the Chicago Eye, Ear, Nose and Throat College. The patient, a man aged 40, had suffered from articular rheumatism for many years. He had had at least five attacks of episcleritis, and each had left small scleral scars with conjunctiva attached. There was a general chronic nodular condition of the sclera a few millimeters from the corneal margin. Atropin and massage had been used, and salicylates internally, but local blood-letting with the artificial leech gave most relief.

The most serious, but fortunately rare, rheumatic affection of the eye is deep scleritis. Here the circumcorneal congestion is more general, showing extensive bluish-red discoloration. It is a chronic disease and destructive to vision by the formation of deposits in the cornea, and staphyloma of the sclera. I showed a case of this type before the Chicago Ophthalmological Society last December. It was that of a young woman of 29, with a history of hip-joint disease at 3 years of age. Since that time her general health had always been good with the exception of rheumatic pains in the joints, always aggravated during changes in the weather. The family history was negative, and there were no evidences of syphilis, except the interstitial character of the corneal deposit. There was violent scleral congestion with triangular corneal opacities, which the magnified cornea showed to be quite vascular. This condition had existed over a year. A period of five weeks was the longest without a relapse. She was treated with potassium iodid, salicylates, salines, and mercury by inunction; locally with atropin, and hot applications and massage. The iris was slightly involved. In this case again leeches gave instant relief during the acute exacerbations.

I have selected these three cases because they represent, in the first two, the most common rheumatic eye disturbances, and the third the most serious in its consequences. Note particularly the history of many relapses; in all a positive rheumatic condition, in one also a family history of it. The case of iritis yielded best to treatment, but so far is not permanent. The two scleral cases are hardly influenced at all except by heat and local blood-letting.

OVULATION AND MENSTRUATION NOT INTERDEPENDENT FUNCTIONS.[*]

C. C. THAYER, M.D.

CLIFTON SPRINGS, N. Y.

From one of the most popular text-books[1] on midwifery in our medical colleges, I quote the following: "The intimate connection between ovulation and menstruation is now admitted by most physiologists, and it is held that the determining cause of the discharge is the periodic maturation of the Graafian follicles. . . . and when the ovaries are removed by operation, menstruation does not take place." One of our latest physiologies, also popular as a text-book[2] in our medical colleges, states the following: "Women do not menstruate when both ovaries have been removed by operation. Some instances have been recently recorded, indeed, of a sanguineous discharge, occurring periodically from the vagina after both ovaries have been removed for disease; and it has been inferred from this that menstruation is a function independent from the ovaries, but this evidence is not conclusive."

Most of us have been educated along the line of the ovula theory of menstruation, and probably most physicians to-day believe that ovulation and menstruation are one and the same thing, or at least duplicate features of a single function. Another view, claiming a respectable and growing minority, divides the thought of the medical profession, and these views are fairly set forth in Gould's "American Year-Book." In an article by Hirst and Dorland, we read: "The divergent views are, first, that ovulation occurs at each menstrual period, and that the two processes are due to the same active cause. The other view is, that ovulation and menstruation are independent of each other, and are due to independent stimuli, and are coincident only by accident."

Since the days of Alexander's "Philosophy of Menstruation," Hamburg, 1841, followed by Grafft, Berlin. 1842, revised and improved by Raciborski, "Habit of Menstruation," Paris, 1868, many others have duplicated their noble efforts, and a clearer and truer understanding and comprehension of the functions of ovulation and menstruation have been gradually introduced into medical thought and literature, so that now many physiologists and gynecologists are concurring in the theory that ovulation and menstruation are naturally coincident, usually concurrent, exceptionally, independent functions. Let us consider this subject from three different standpoints.

1. *Ovulation without Menstruation.*—In Kirke's Physiology,[2] we read: "Cases are known where ova have been discharged in amenorrheic women. It must, therefore, be admitted that menstruation is not dependent on the maturation and discharge of ova." This statement is in harmony with the frequent observations of many gynecologists. Frequently mothers consult their physicians in regard to their daughters, in age ranging from 14 to 18, well-developed girls, who are having regular periodic ovarian disturbances, as regular and complete, minus the menstrual flow, as their mothers did. Perhaps this does not prove that these ovarian disturbances were ovulation; yet had these symptoms been attended with the customary discharge, ovulation would have no longer been considered hypothetical. While we have in the young, substantial proof as to when the menstrual flow began, we have no substantial proof as to when ovulation began.

We have had many patients who have menstruated for years and suddenly became amenorrheic, yet monthly had their regular periodic ovarian disturbances, less the external manifestations, and afterward when the flow reappeared it was when they were having these periodic attacks, suggesting at least that the ovaries had been performing their functions, though the uterus had failed to respond with its associated function.

In the year 1881, a young lady came under my care, who at the age of 21 attended the National Centennial, at Philadelphia, and was menstruating at that time. She took cold; the catamenia ceased and she saw no more of it for five successive years, though she experienced for about a year her regular, periodic ovarian disturbances, until gradually they ceased with her failing health. During the fifth year and after about six months' treatment, she noticed the return of the regular ovulation symptoms, and after three or four months more the regular menstrual flow appeared.

During a recent visit to Florida I was consulted by a well-developed, hearty young lady of 18 years, who gave the following history of herself: "About five years ago I began to have bad feelings in my head, back and sides, reaching through the bowels, which I could not account for. They seemed to come on about every four weeks, lasting two or three days each time and seemed always the same. Latterly, these spells have seemed worse. When I have taken medicine for them it has done me no good, and I have become anxious about my health." Recognizing the usual symptoms of menstrual disturbance, I asked her if she thought these pains were connected with her menstruation. She replied: "I never menstruated, but feel as other girls tell me they feel when they are sick, and I would like to know why I do not menstruate." A day having been appointed, another physician and myself examined her, when we found a complete vaginal atresia. By manual exploration through the bladder and rectum we discovered a rudimentary uterus, but not a vestige of a vagina. The clitoris and majora were intact, but no evidence of hymen. All other parts were normal. Considering her health and womanly development, what did these regular periodic symptoms signify but ovulation? Another day was appointed, when Dr. Bishop, of Sandford, assisted, acompanied with a surgeon, and while the young lady was under the anesthesia, the flesh corresponding to the place and size of the natural hymen. and to the thickness of blotting-paper was dissected off in pursuit of a vagina, but no vagina was found. There were two little holes, bilateral, about three-fourths of an inch apart, disclosing two passages about the size of an ordinary knitting needle and extending upward about four inches; surrounding these the tissues were dense but healthy.

---

[*] Presented to the Section on Obstetrics and Diseases of Women, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

"That ovulation may and does occur apart from menstruation," says Dr. Martin, in his physiology and histology, quoted from Hirst,[4] "seems to be proved by such cases as that of Oldham. In that instance the ovaries had descended into the labia majora, and every three or four weeks one or both swelled and became tender. The uterus and vagina were absent."

One of the most frequent and familiar symptoms to a gynecologist, is swelling and tenderness over the ovaries, discovered on digital examination from one to three days previous to the menstrual flow, and a like digital examination, showing less swelling and tenderness, some time before or soon after the flow has begun, indicating that the ovarian changes and constitutional disturbances may be independent of menstruation in these cases as in the cases above cited, where, in the young, the ovaries had matured faster than the uterus and had entered their functional mission before the uterus was ready to express, by the usual sanguineous discharge, its readiness to co-operate in this usually associated phenomenon. The same is true also in the other above-cited cases of amenorrhea where there were the usual ovarian symptoms present, but the menstrual flow absent.

When we consider ovulation in its simple and independent character, as exhibited in nature's scaly and feathered tribes, which is unattended with a menstrual flow, we are compelled to admit that ovulation in the mammiferous, though periodic, is as natural as in the fish or fowl; and the period is not dependent on the moon, or contact with a male, or on genitalia congestion, or on the menstrual flow, but on the nature of things. The period of ovulation being as natural as the interval, we are compelled to admit that ovulation is the primary and initial organic step in nature's progressive effort to procreate, and that ovulation, therefore, being primary, initial and independent, the uterine changes, blood discharge, venous congestion, heat, etc., usually concurrent phenomena, are necessarily only secondary: and while the uterine changes are secondary, usually they are intimately associated with ovarian changes, especially in the attainment of nature's purpose in an ultimate end of ovulation, namely, procreation. Yet in view of the many incontrovertible and incontestable facts reaching through many years of painstaking study and creditable observation in different parts of the land and in different lands, we are compelled to believe, that exceptionally, and by no means solitary, there may be ovulation and even conception without menstruation. Let us pursue this general subject from another standpoint.

2. *Menstruation without Ovulation.*—In the foregoing discussion we have cited numerous authors and clinical cases, showing that ovulation and menstruation are coincident, but not interdependent; that ovulation is the primary and initial step in nature's process of recreation, called menstruation, and that the menstrual flow is the secondary act in the same process, usually attendant, but exceptionally absent and may occur independent of ovulation.

A glance at the anatomy of the blood and nerve supply of the ovaries and uterus will aid us in the discussion of the functions. The arterial supply of the ovaries is from the ovarian branch of the aorta. The arteries of the uterus are the uterine and a branch from the ovarian. The uterine artery is a branch of the internal iliac, supplying the walls and viscera of the pelvis and generative organs except the ovaries, so that the blood-supply is quite out of proportion in the two organs, and is mainly from different sources. The nerve-supply to these organs is abundant and from the sympathetic system. The nerves of the ovaries are from the spermatic or ovarian plexus. The nerves of the uterus are from the inferior hypogastric, some from the ovarian, and from the third and fourth sacral nerves. The uterine nerves are not distributed through the ovaries, but to the uterus, vagina and bladder.

The blood and nerve supply being mainly from different sources, suggests the probability that there might be an ovarian activity without a corresponding uterine activity and vice versa; ovulation without menstruation or menstruation without ovulation.

The menstrual flow, beyond reasonable controversy, is produced from the mucous membrane lining the uterus, and is entirely independent of rupture of the Graafian follicles. Exactly how it is produced is still a mooted question. Some hold that it is a natural result of a periodic vascular congestion, throwing off the membranes and leaving the surface raw and bloody. Others say it is produced by exudation from open-mouthed blood-vessels, which terminate in the mucous membrane. Still others hold that it is produced by turgescence and vascular osmosis. Of still less value are the theories that the blood is produced by the presence of the ova in the uterus or by congestion of the Fallopian tubes; from ovarian activities and rupture of the Graafian follicles, or the theory of monthly, periodic uterine muscular contraction forcing the flow. But it is important in this anatomical reference to bear in mind that the blood and nerve supply are essentially from different sources.

Now let us return to the consideration of the menstrual function. Again, we quote from Kirke's "Physiology," "Though menstruation does not appear to depend on the discharge of the ova, yet the presence of ovaries seems necessary for the performance of the function." The statement that menstruation does not appear to depend on the discharge of the ova, appears to us more in accord with clinical observation than either theories, namely, of Bischoff and Pflugar, on the one hand, that "ovulation and menstruation are due to the same active cause, the one being the starting-point of the other," [5] and the theory of the extreme party, on the other hand, represented by Biegel, quoted by Professor Schroeder,[6] of Bavaria, that "ovulation and menstruation are completely independent of one another, and that the discharge of the ovum may take place at any time whatever, even in children, but that menstruation is nothing but the periodical returning demand of the female genital organs for sexual gratification." Professor Schroeder's own views are more in accord with recent developments, namely, "That it is clear, that the two phenomena have no necessary and absolute connection, and that the occurrence of one without the other is quite conceivable."

In physiological menopause does ovulation or the menstrual flow cease first? Do they cease together? Do the irregularities of the menstrual flow, or the frequent and prolonged hemorrhages during the change have to do with ovulation? Physicians see many cases where menstruation continues long after the age of child-bearing, and, we conclude, long after the age of ovulation. I had a patient who menstruated once in about three months at the age of 73. I have the assurance of one who menstruated regularly between 75 and 80; but we hear of no pregnancies so late in life. However, Sarah, Mrs. Abraham, bore her husband a son at the age of 100, and why not, if ovulation continues, other things being equal?

Painstaking observation of surgical cases for the last twenty years seems to prove conclusively that menstruation has continued periodically and regularly after both ovaries have been removed. This is corroborated by the majority of the latest works on surgery and gynecology, though denied by such men as Dorant, Baker, and Dormer Harris,[2] who say: "Some instances have been recently recorded, indeed, of a sanguineous discharge, occurring periodically from the vagina after both ovaries have been previously removed by disease; and it has been inferred from this that menstruation is a function independent of the ovary; but this evidence is not conclusive. A lady came under my care, who some months previous had a double oophorectomy performed; she told me that her menstrual periods had been as regular after as before the operation. Another young lady had a like operation and after three months began to menstruate regularly and continued for three years, when hysterectomy was performed. I attended her in both operations. Gill Wylie[5] reports Lawson Tait as saying: "Women sometimes menstruate regularly when both tubes and both ovaries have been removed. I know of one who has missed not more than two menstruations in two years and a half, although I have both of her tubes and ovaries in a jar." I have, at present, one under my care who, two years ago, had both ovaries removed and has menstruated as regularly since as before.

Again, in considering the independent action of the functions of ovulation and menstruation, let us look at it from still another standpoint.

3. *Conception without Menstruation.*—If there be truth in the subject of this paper, namely, that the two named functions of generation in the female are not interdependent; if anatomy and physiology have so provided; and if surgery, clinical history and painstaking observations sustain this truth, then we can conceive of the possibility of even conception without menstruation, which, if it should occur, would prove an independence of the functions of the ovaries and uterus.

Dr. Jaggard[7] says: "Pregnancy may occur in the absence of menstruation." He further says: "There are also authentic cases on record of pregnancy after the climacteric." I attended a gray-haired lady in confinement at the age of 50 and past, who supposed she had passed the change of life long before. Dr. Hodge[7] cites a case coming under his own observation of a woman who became pregnant seven months after the last appearance of menstruation.

Several cases have occurred in my practice of women becoming pregnant during lactation and before the reappearance of the menses. A young girl may become pregnant before she menstruates. "The Hindoos[11] have a custom that their girls shall be obliged to marry before the establishment of the menses, because even menstruation occurring in a girl who has not had the opportunity to conceive is regarded as infanticide." [8] Medical missionaries are conversant with this phenomena in tropical countries where girls often marry before the age of 10 and sometimes children are born before their teens. Kussmaul reports a case of one who became pregnant at the age of 8 and bore a child nine months later.[9] Fox,[10] of Philadelphia, speaks of attending a girl in confinement at the age of 11 years and 4 months. The Mohammedans in Syria and Asia Minor, among whom I lived for several years, often marry their daughters before the catamenia and it was often said that a child was born before the menstruation. Menstruation is seen, therefore, to be no integral part of ovulation, nor an absolute factor of conception, though usually concurrent and attendant.

There may be ovulation without menstruation; menstruation without ovulation; and conception without menstruation.

DYSMENORRHEA.*

GEORGE TUCKER HARRISON, M.A., M.D.
Obstetrician to the New York Infant Asylum; Fellow of the New York State Association; Honorable Fellow of the Medical Society of Virginia, Etc.
NEW YORK CITY.

That group of phenomena comprehended under the term dysmenorrhea is as interesting as it is common in the experience of every practitioner of medicine, nor is the interest lessened by the reflection that on the successful management of the case in which such symptoms occur, often depends the reputation of the physician concerned, among a large number of patrons. That the problem is frequently a difficult one will hardly be gainsaid. It can not, therefore, be time misspent if we devote the few minutes at our disposal to the study of the etiology and rational treatment of the abnormal conditions underlying these morbid manifestations. Recent investigations have thrown light on the innervation of the ovary and the uterus, respectively, which greatly facilitate our understanding of the symptoms, especially in organs remote from the genital sphere. The nerves of the ovary originate from the plexus renalis and lower section of the plexus aorticus seu spermaticus, and belong almost entirely to the sympathetic system. They obtain, however, spinal filaments by means of communicating branches of the nervus spermaticus externus, which owes its origin to a branch of the nervus genitofemoralis originating from the plexus lumbalis; it joins the plexus spermaticus.

---

*Presented to the Section on Obstetrics and Diseases of Women, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

According to the researches of Otto V. Herff,[1] there exists in the ovarian stroma a very dense nervous plexus which is mainly designed to supply all vessels, including those of the follicles. Nerves also attain to the follicular epithelium, lying on the smallest follicles, but sending filaments into the largest ones, which radiate into the membrana granulosa and end here. Moreover, here and there filaments attain to the germinal epithelium as well as to the muscular cells in the hilus and to the inner vascular layer. Devos[2] finds that the plexus surrounding the follicles has no connection with the vascular nerves. He considers, therefore, the follicular nerves as centripetal and believes that their stimulation has influence on the entire nervous network of the utero-vaginal domain. The result of the studies of Winterhalter are embraced in the two propositions: 1. The ovarian vessels are surrounded with perivascular plexuses. 2. In the zona vasculosa lies a ganglion consisting of cells of the character of the sympathetic ganglion-cells, and its processes surround the vessels for the greater part in numerous convolutions.

Bearing in mind that the physiologic function of the ganglion-cells is to preserve and accumulate stimuli coming to them for a considerable time, and to discharge these stimuli directly or indirectly through the intervention of other cells as soon as the stimulative height has overstepped a certain limit, we are logically forced to the assumption that menstruation is a reflex process starting from the ovaries.

In the language of Maericke, "the excitations which the Graafian follicle exerts on the nerves surrounding it, partly by its growth, partly by the chemical processes occurring in it at the time of sexual maturity, are deposited and accumulated through the instrumentality of these nerves in the spinal marrow or in the ganglia of Frankenhauser and Winterhalter; perhaps in others also.

"When the stimuli have thus attained a certain height a discharge follows in the form of a powerful congestion of the blood in the genitalia."

The nerves of the uterus are derived in part from the plexus hypogastricus and in part from the sacral nerves. The hypogastric plexus lies on each side, immediately on the promontory about 3 centimeters beneath the bifurcation of the aorta, and forms a combination of the plexus spermaticus and renalis. From the two last-named plexuses fibers go upward to the celiac plexus. The most important roots of the plexus coeliacus are the nervi splanchni and the abdominal branches of the pneumogastric—chiefly the right. It also receives contributions from the phrenic nerves. Herlitzka, in his valuable contribution to the study of innervation of the uterus, says: "In the tissue of the uterus we find, besides the plexus belonging to the vessels, two other nervous elements entirely different from one another in structure and derivation. 1. A network consisting of ramified cells whose processes anastomose with one another in a manifold manner. It stands in communication with strong bundles consisting of pale fibers of Remak. These elements probably are derived from the sympathetic system. These cells are not to be considered as ganglion-cells; it may rather be assumed that to them belongs simply the conduction of the nervous excitations. 2. Some myelin-containing fibers which exhibit the same properties as all nerves derived from the cerebrospinal axis. These fibers end with extensive ramifications of a characteristic appearance, and are distributed over wide zones of uterine tissue without, however, entering into communication with the elements of the proper network or with the fiber-cells of the muscles."

These anatomical descriptions plainly show the source and extent of the distribution of the cerebrospinal and sympathetic nerves to the pelvic organs, at the same time demonstrating the communication between them. Another anatomical feature must be kept in view, namely, that in the sympathetic paths, vasomotory, motory, secretory and sensory fibers run; and such cerebral nerves as the pneumogastric and trifacial maintain communication with sympathetic ganglia. We shall not be at a loss, therefore, to explain the various morbid phenomena of dysmenorrhea, however incomprehensible they may appear to the student of medicine who ignores anatomical research.

Women who enjoy excellent health at the time of menstruation feel a change in their physical condition, as the very term they use denotes—they are "unwell." Independently of an increased susceptibility of the nervous system to external impressions, they may complain of certain local annoyances, as heaviness, or fulness in the region of the pelvis, a sensation of pulling in the sacrum, a frequent desire to void urine, etc. Dr. Emmet thus expresses it: "Every woman, even in health, will experience some degree of discomfort at the menstrual period. That she should be absolutely free from pain and suffer no inconvenience at the time is an abnormal condition." I can hardly follow the eminent gynecologist here and accept these views without qualification. That, as a rule, healthy women have more or less discomfort when they menstruate is true, but it is equally true that we by no means infrequently meet such women who say that menstruation takes place absolutely without pain. If women in good health, therefore, complain of discomfort in menstruation, it need not excite surprise if women affected with the various pathologic conditions underlying dysmenorrhea present many and varied phenomena. In most cases the complaints begin long before the appearance of the period, and reach their highest point in intensity during it, then die away slowly and by degrees. Sometimes the pains come on shortly before the menstrual flow, and promptly cease when this begins. Others have the pains only during the flow, still others, before and during the period. Some have only a dull burning or gnawing sensation in the pelvis; in the case of others the pains radiate in a wide circle, and are perceived at distant parts of the back. In some the pain is more or less continuous, while in others exacerbations alternate with remissions. In many the pains are perceived and described as plain uterine contractions. To these symptoms are often added great irritability of the bladder; the patient has an urgent desire to pass urine every few minutes, and the results of her efforts in this direction are only a few drops. Disturbances of the digestive tract are frequently present; constipation alternates with diarrhea, the latter symptom being the more common. Heartburn, nausea and vomiting are as frequent as they are annoying. Attacks of severe hemicrania, which may be present for days, give the patient no rest. Cardiac palpitations, cold sweats, and attacks of syncope are manifestations evoked from the circulatory system. If no help comes, her condition may steadily and progressively depreciate. The pains become constant; the fear of the next menstruation, which hangs like the sword of Damocles over the unfortunate woman, the exhaustion that ensues from the pain during the period, the inability to enjoy life and perform properly its duties, and the disappointment at the failure of conception induce sooner or later a state of invalidism distressing beyond description. The exasperating character of the pains and the attendant depression of spirits often impel the unhappy sufferer to call to her aid a force as potent as it is destructive, in the end, to mind and body. She becomes addicted to the use of narcotics, especially morphin; it is certainly correct that dysmenorrhea furnishes a large quota to the contingent of morphin habitués.

---

[1] Zeitschrift f. Geb. u. Gyn., Bd. xxiv, Hft. 2.

[2] Jahresberichte von Frommeil, 1891.

With reference to the causes of dysmenorrhea, most modern writers refer the phenomena in question to diseases of the uterus, the tubes, the ovaries, the peritoneal covering of these organs as well as the pelvic connective tissue. In the preponderating majority of cases the morbid affections which are the etiologic factors are inflammatory processes. Hence the classification: 1. causes originating in the uterus, and 2, causes which are extrauterine. This extension of the term dysmenorrhea so as to make it include all the painful symptoms evoked by inflammatory affections of the adnexa and their serous investments is a great mistake, an egregious blunder, and leads to confusion of thought.

Inflammatory affections of these organs, in consequence of the fluxion of menstruation, do at times undergo changes for the worst, but on the other hand I have been repeatedly struck by the fact that the symptoms improved decidedly during the flow. Moreover, in tubal or ovarian disease the dysmenorrhea is a mere incident and not the all-important determining factor in the clinical picture. The proper type of dysmenorrhea is the retention, mechanically, of menstrual blood, as it is observed in its most pronounced form, in cases of occlusion of the genital tract consequent on arrest of development. Similarly its symptoms are manifested, although not so clearly or unequivocally in all forms of narrowing of the cervical canal as in stenosis of the external os, flexion consequent on pathological anteflexion, flexion occurring in retroflexion, and in the narrowing caused by tumors, especially myomata. It is impossible to state in general terms how excessive the narrowing must be in order to cause retention of the uterine contents. Whilst coagula or shreds of the uterine mucous membrane are able to pass through a quite wide cervix only with difficulty, on the other hand, fluid blood makes its way through a very narrow cervix with comparative ease. But this is only true when the blood is secreted by the uterine mucosa slowly. In these cases there is always a mechanical distention of the uterine cavity, to which the muscular tissues of the body respond with contractions causing labor-like pains or uterine colic. The pains are paroxysmal and at times attain a high degree of intensity. When the flow becomes free they may intermit, but in other cases they persist during the entire time of menstruation.

The great apostle of the mechanical explanation of dysmenorrhea was that rare genius to whose labors gynecological surgery owes an unpayable debt, J. Marion Sims. It has been attacked, it is true, by most modern writers, one of the ablest being Heinrich Fritsch, for whose learning and sagacity I have the highest admiration, but notwithstanding I believe it rests, in the main, on impregnable ground. Fritsch says: "The mechanical explanation of dysmenorrhea played a great rôle with Marion Sims. It was said that the inner os uteri was partly actually narrowed as a complication, and partly was contracted owing to the fact that the uterus was flexed in this place. If blood was now effused into the uterus it could not escape, consequently uterine contraction originated, and this constituted dysmenorrhea. . . . Against this view speaks the following: 1. The pains have not the plain character of labor-like pain, are not at all limited to the uterus, but are felt in the entire hypogastrium and in the thighs. 2. It is proved by sounding that the pains are frequently present before a drop of blood is found in the uterus. The pains by no means disappear when the blood has free egress; nay, just in the worst cases so little blood is secreted that it can by no possibility stimulate the uterus to contractions. 3. The fluid blood is not to be identified with a firm foreign body stimulating the contractions. Coagula just in these cases are never found. The uterus does not react by dysmenorrheal pains even on the formation of polypi, on the sound, on accumulations of mucus, on intrauterine treatment. 4. The menstruation in the same patient is at times painful, and with appropriate therapeutical measures quite free from pain. Menstruation in a wide uterus may be very painful when it is inflamed or lies in a bad position. 5. Quite the same condition is observed in a quite normally formed uterus. The pains in uncomplicated cases are to be explained in the following way: We know that the mucous membrane swells very considerably in menstruation and that the uterus also becomes larger. The resistance of the uterus to this thickening of the mucous membrane and the dilatation of the bloodvessels produce contraction and pain. Dysmenorrhea is frequent, therefore, in a badly developed, small nulliparous uterus, but is wanting in the healthy, yielding uterus of a multipara whose vessels and cavity are wide. A strongly flexed uterus will oppose greater difficulties to the thickening of the mucous membrane and the uniform distention than a completely normal one. It must be borne in mind, in addition, that the swelling mucous membrane, in menstruation, forces the mucus out of the uterus and almost always some discharge precedes the menstruation. If this mucus cannot escape on account of stenosis of the os uteri, or on account of strong anteflexion, or on account of polypus, also if the blood is retained, the mucous membrane is prevented from swelling. The use of the sound will help here. This view has much affinity with the assumption of Sims, for which the success of the operative measures plainly speaks. After a birth the dysmenorrhea ceases as a rule, because the vessels and the muscular tissue likewise remain dilated."

This admission on the part of Fritsch is all that the advocate for the mechanical view could wish, and at the same time shows that with the eminent gynecologist love of truth weighs more than the reputation for dialectic skill. Küstner insists that the exclusive mechanical view of dysmenorrhea must be allowed to drop, but at the same time admits that we can moderate or heal the dysmenorrhea if the contractions of the uterus are removed or limited in some degree by eliminating their cause; that is to say, if so easy a way of escape is made for the uterine contents that contractions are not called forth, or at any rate to only a limited degree. He also finds the underlying cause of the phenomena in inflammatory conditions of the uterus and the adnexa and their peritoneal investment. August Martin believes that one of the most frequent[3] complaints of women, the subject of salpingitis, refers to dysmenorrhea; at the same time he expressly states that the pains are increased during menstruation in some cases, while in other cases they undergo amelioration. He further states that in reference to the dysmenorrhea in salpingitis it must remain questionable what share the uterus and what the peritoneum has in the pains, "even if the pains are decidedly localized in the tubes." We thus see what a confused, hazy clinical picture we obtain of dysmenorrhea if we bring under its definition all the inflammatory affections of the pelvis, while on the contrary it is clear and intelligible in all its details if we regard it as a neurosis originating when the uterus finding an obstacle to the evacuation of its contents, responds by spasmodic contraction of its muscles. All other pains, whether occurring during menstruation or at other times, and proceeding from endometritis, metritis, perimetritis, oophoritis or salpingitis, are absolutely excluded from a proper conception of dysmenorrhea.

I by no means wish to deny, however, that dysmenorrhea in its full type, if allowed to persist unchecked, will undoubtedly cause oophoritis and endometritis. A peculiar form of dysmenorrhea, called intermenstrual pain, has lately attracted much attention. Halliday Croom devotes considerable space to its discussion in his article in Allbutt's "Practice of Medicine." It is a misnomer to speak of it as dysmenorrhea, and I agree with Fritsch in regarding it as a symptom of endometritis. A form of dysmenorrhea, which is of special interest to the general practitioner, is the pain accompanying menstruation in young girls soon after the establishment of this function. In these cases the explanation will usually be found in the fact that the uterus is backward in its development and consequently is unable to meet the demands made on it by the menstrual process. The blood-vessels especially possess too slight a caliber and are inadequate to the menstrual fluxion. The mucous membrane is thus not able to swell properly and perform its functions. The abnormal increase of pressure in the uterine vessels, which is normally relieved by a free flow of blood, evokes now, reflex contractions of the uterus, which are increased from the fact that the uterus, in consequence of the smallness of its cavity, is unable to hold the secreted blood. It is not to be denied that there are cases of severe dysmenorrhea in which the source of the disease must be sought, not in the uterus, but in the general system, especially the nervous system. The subjects of this type are neurasthenic or hysterical. They are, as a rule, badly nourished, anemic, chlorotic individuals, with a hereditary tendency to nervous and psychical disturbance.

Dr. William Fliess, of Berlin, has called attention to a peculiar form of dysmenorrhea which he designates by the term nasal form of dysmenorrhea. According to this author, there are certain points in the nose called by him "genital places," particularly the inferior turbinate bones and the tubercular septi, which undergo changes during menstruation, under certain conditions in consequence of which dysmenorrhea is evoked as a reflex phenomenon. The application of cocain to this part of the nasal mucous membrane will alleviate the dysmenorrhea, while cauterization will effect a permanent cure.

The relation between the nose and the sexual organs deserves more attention than it has heretofore received, but meanwhile it must remain a subject for further investigation.

That form of dysmenorrhea called forth by an endometric exfoliation presents a group of symptoms which may be considered as a pure type of dysmenorrhea. The symptoms are necessarily more pronounced than in ordinary cases, especially the rhythmical contractions, since a stronger force is requisite for the passage of a solid membrane than for the expulsion of fluid blood. Recognizing the fact that the dysmenorrhea is a neurosis and that the characteristic pain is to be referred to spasmodic contractions of the uterine muscular tissue, which manifest themselves when the menstrual blood effused into the cavity finds an obstacle to its discharge through a narrow or flexal canal, the indications of treatment are obvious. In the uncomplicated dysmenorrhea of young girls a vaginal examination is unnecessary. The general health should be promoted by tonics, proper exercise, attention to the state of the bowels, and to act on the uterus, the fluid extract of hydrastis—a teaspoonful three times daily—should be exhibited during the free interval. If the pain persists it may be necessary to resort to the use of a suppository containing aqueous extract of opium or morphin, and thus the patient may be permanently relieved. I need scarce remind you that a frequent recourse to the use of opium is manifestly contraindicated. Antipyrin has shown in my hands wonderful power in relieving the pain of dysmenorrhea. It may be exhibited by the mouth or hypodermically. It should be borne in mind, however, that it is very depressing in its action on the heart, and its effects must be carefully watched. Of all the coal-tar derivatives, phenalgin in 5-grain doses once every hour or two until the pains cease, has rendered me the greatest satisfaction. Apiol exhibited twice daily for some days previous to menstruation is a valuable acquisition to the remedies.

If these simpler measures prove inefficient, it will be necessary to resort to local treatment. In cases of hypoplagia or pathological anteflexion, cure may be effected by recourse to a gradual dilatation by Hegar's dilators, or, as I prefer, by steel sounds. McGinnis praises highly the use of electric treatment. In chlorosis and nervous phenomena he applies one electrode on the abdomen the other in the lumbar region. In cases of "pure uterine dysmenorrhea," he applies the positive pole in the cavity of the uterus.

If in spite of these local measures the dysmenorrhea recurs, an excellent method is to dilate with laminaria tents. I agree entirely in the view expressed by Fritsch that by this gradual dilatation better results can be obtained than by the use of forcible dilatation at one sitting. A small tent, properly bent and aseptic, is first introduced, the patient being in Sim's position and the uterus fixed by a bullet forceps, and allowed to remain twenty-four hours. Iodoform gauze is placed against the os uteri and the vagina packed. A second is similarly introduced and allowed to stay twenty-four hours, and so on until the cavity is sufficiently large to admit the finger. The uterine cavity is then packed tightly with iodoform gauze and this is kept intact for two days. If this treatment is conducted according to strict principles of asepsis and antisepsis, no infection may be feared. As Fritsch correctly observes, "the next menstruation may be still painful in consequence of irritation of the nerves, but afterward menstruation occurs without pain."

---

[3] Die Krankheiten der Eileiter, Leipzig, 1895.

I have heard gynecologists declare that they never make use of tents, that such methods are antiquated; but in this class of cases the laminaria tent unfolds a power that can be equaled by no other known plan of treatment. In cases complicated by chronic endometritis and in those in which a myoma is situated in the uterine wall I make use by preference of the dilator of Pryor, which possesses many advantages over the ordinary dilators, for the purpose of thorough dilatation. The uterus is then curetted with the Sims sharp curette and tightly packed with strips of iodoform gauze. In this way the dysmenorrhea is cured with the endometritis.

For the membranous form I use the same method of treatment with decided benefit. Fritsch recommends the prolonged use of uterine irrigations of lysol, 1 to 100, after thorough dilatation, and this method is well worthy of adoption. Finally, it should be mentioned that oophorectomy has been recommended as a last resort in cases of persistent and obstinate dysmenorrhea. Against this practice I must make my decided protest; in the first place we have no certain guarantee that the patient's condition will be better after the operation than before, and secondly with the less radical means at our command I am absolutely sure that we can attain the desired goal by persistence, patience, and wise discrimination.

TREATMENT OF MENORRHALGIA OF PELVIC ORIGIN BY ELECTRICITY.*

G. BETTON MASSEY, M.D.
PHILADELPHIA.

What are we to do for the relief of our young women patients who suffer persistently from menstrual pain and spasm? I allude to those cases which have resisted all approved drug medication, including alimentary correctives and eliminants, as well as antispasmodics, and whose life is clouded during one-fourth of each month by an ever-increasing degree of morphia stupefaction as the only relief from intense pain.

The pathology of cases of this nature is usually of a dual character. There is commonly a chronic inflammatory process present in the endometrium, accompanied by congestive conditions in the ovary, the endometritis being merely catarrhal, and there is also a most pronounced erethism of the pelvic neuromuscular apparatus. This neuromuscular erethism is the feature wherein these cases differ so greatly from those of mere endometritis in parous women, unaccompanied by the menorrhalgic spasms. The pain and spasm are probably present in the younger women because of developmental imperfection, the result being very much like a tic-douloureux due to a bad tooth. Should pregnancy occur a spontaneous cure is probable, not because the cervical cavity is then larger, as incorrectly supposed by some, but because a full development of the organs has been produced by the remarkable trophic accompaniments of the gravid state.

The idea that dysmenorrhea is due to obstruction of the menstrual flow has been shown to be a delusion. No accumulation is ever found in these cases. The steel dilators that are still improperly employed in a treatment based on this obsolete theory themselves disprove the presence of obstruction, for a canal that will admit them in their closed state is far larger than necessary as a hydraulic drain for the menstrual fluid. If the purpose in view, in the use of these instruments for forced dilatation under ether, is not the *permanent* enlargement of the canal, but the mere divulsion of the spasmodic stricture, it follows that the method should be employed only during the actual spasm of the period, and should be repeated at each period, conditions never present in these operations as advised in the books.

The truth is, that this formidable operation, the forcible dilatation of the cervical canal by steel dilators, oftener does harm than good; the cases temporarily relieved rarely experiencing comfort more than during one period, and this probably owing to an amelioration of the endometritis. The harm at times done by the operation is, on the other hand, an actual aggravation of the subacute catarrhal condition, ending, in some instances, in an ascending catarrh of the tubes and ovaries.

Too often the final history of a case which has been placed under forcible dilatation, is abdominal section for removal of inflamed ovaries. This result may at times be merely in spite of the treatment, which failed to cure the case in its first stages; but in other cases I have the unquestionable testimony of patients and their physicians that what had been merely menstrual pain in the uterus and back before dilatation, was changed to constant pain in the ovarian regions after dilatation, and this without relief from the menstrual pains.

There are at present a large number of physicians in this country who agree with me that in electricity we have a most valuable remedy for the permanent cure of persistent menorrhalgia, even of the most severe forms. Unfortunately, little is written at present from this point of view, and the unopposed views of the wisdom of dilatation remain uncontradicted. The method may be carried out in office practice, is free from risk to already congested appendages, and may be relied on to cure when conjoined with intelligent regulation of the general health and habits of the patient.

I have given the exact technique elsewhere, but may say that it consists of judicious blending of vagino-abdominal applications of the positive pole of the galvanic current with similar intrauterine applications of the same current. The intrauterine applications must not be used, however, until the congestive condition of the appendages is relieved, after which the local effect of mild mercuric cataphoresis within the cavity will quickly remove the endometritis, which, having its inception in "catching cold" during a period, is the initial lesion of the affection.

It will be noticed that I recommend that the positive pole of the galvanic current be used and not the negative. This choice is deliberately made as the result of large experience, and shows that electricity does not owe its value in these cases to a dilating effect, as some think, this effect being greatest at the negative pole, but rather to the cure of the endometritis. If there is no endometritis I do not pass the electrode within the uterus at all, but apply the internal electrode within the vagina alone.

I would urge an intelligent use of electricity in this condition on the part of all physicians engaged in general office practice. Expertness is readily gained by those equipped with sufficient gynecological and electrical training, and though the actual work will require some time and trouble, the result can not be other than pleasing when it keeps the patient at home, makes her a well woman, and robs an operating-room of another sexless product.

---

*Presented to the Section on Obstetrics and Diseases of Women, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

DISCUSSION ON PAPERS OF DRS. THAYER, HARRISON AND MASSEY.

Dr. E. G. Zinke, Cincinnati, Ohio—This is a subject with which we are all more or less familiar, but we all differ as to the proper treatment of the various cases. I have listened very attentively, and I must say that I have heard nothing especially new. So, too, the criticism I may make is not particularly new. I have ceased to use electricity for fully eight years in the treatment of gynecologic cases. I have purchased hundreds of dollars worth of apparatus for this work, but have derived absolutely no benefit from it, especially in the treatment of dysmenorrhea. I am free to admit that in some of these cases I did not, in all probability, determine the real cause of the trouble. When a case of dysmenorrhea presents itself to me now, I make every effort to determine the cause. Those cases which are amenable to treatment at all can be cured without the use of electricity. The most difficult are those in unmarried women, especially when under 18 years of age; in these it is exceedingly difficult to determine the nature of the trouble unless an examination is made, and this is not always advisable or possible. We might treat the patient from a neurotic standpoint, but we should not waste too much time. After temporizing for awhile and failing to relieve the patient, I invariably insist on examination under the influence of an anesthetic. If we can exclude want of development of the generative organs not much can be accomplished by electricity. We should pay attention to the general health of the patient, proper diet, daily action of the bowels, outdoor exercise, change of climate and good habits, especially in girls who go to school or who work in ill-ventilated tailor shops, where they are obliged to sit for eight or ten hours in a cramped, unnatural position, breathing bad air. When we find a want of development or diseased conditions, we must give them the proper treatment, and I am sure that in cases of endometritis, metritis, salpingitis or oöphoritis the least beneficial treatment is electricity. I have absolutely no use for it in my practice.

Dr. Maximilian Herzog, Chicago—I wish to put myself on record as against the view that menstruation and ovulation are absolutely independent of each other. Truly, it is a fact that ovulation occurs without menstruation. It is also true that we have hemorrhages from the uterus, which are menstrual in character, without ovulation, but the exception only proves the rule. It was formerly claimed that *in menstruation the major* part of the uterine mucosa is shed. This view was derived from the examination of post-mortem material, which is unfit for studies of this kind. We must examine menstruating uteri obtained from the living if we wish to make correct observations. I am in a position to confirm the statements of Mandel and others that there is little of the uterine mucosa shed in menstruation, and that little consists only of some of the superficial epithelial cells. I have made this observation repeatedly on menstruating uteri obtained *per operationem* from the living. The changes which do occur in menstruation are the following: The capillaries of the intertubular connective tissue are enormously dilated and there is an extravasation of blood into the connective tissue. Some of the blood makes its exit toward the surface, and some of the surface epithelia are lifted away from their basement membrane and shed. Those are all the changes we find in a normal menstruating uterus. The object of this change is to prepare the soil for an impregnated ovum. It has recently been shown by Peters and others, that the human ovum, like that of lower animals, when it first begins to develop in the uterus, is surrounded by a solid layer of ectoblast with phagocytic properties. The changes occurring in menstruation are for the purpose of allowing the *implantation* of the ovum. The changes in the uterus in menstruation serve a specific purpose, viz., to prepare the soil for *an impregnated* ovum, and they therefore do stand in a certain *relation to* ovulation.

Regarding dysmenorrhea, our knowledge of the pathology of this condition is a very hazy one. Our classification of dysmenorrhea is incorrect. Obstruction to the menstrual flow plays a very insignificant rôle in the causation of dysmenorrhea. There are practically only two types of dysmenorrhea. One which is dependent on inflammatory changes in the uterine mucosa and the other dependent on inflammatory changes in the ovary. The inflammatory changes of the uterine mucosa are of the type of an endometritis interstitialis. In cases where the membrane is shed the uterine mucosa undergoes a change much like that in normal menstruation, except that the limit is overstepped and we have the formation of tissue very much resembling a young decidua. Several interesting papers on certain forms of oöphoritis characterized by changes in the vessel walls have recently been published. In these forms of oöphoritis we find processes of endarteritis obliterans and hyaline changes in vessel walls. We know little of the cause or causes of most cases of oöphoritis.

Some time ago I studied the histopathology of syphilis, and I have *been able to confirm the work of* Rieder, who found that the vessel changes in *syphilis are mostly found* in the veins and lymphatics *and not in the arteries*. I have examined a number from cases of dysmenorrhea, and found conditions very much resembling those found in syphilis. It occurred to me that it is possible that there are certain cases of oöphoritis which are of syphilitic origin. There is, however, nothing definite known as yet about this point, but I think it *would* be worth while if the gynecologist would keep in *mind* that certain forms of oöphoritis are probably *due to congenital* or *acquired syphilis*. In such cases mercury and the iodids would *probably be of greater service* than the knife.

Dr. George J. Engelman, *Boston*—I have always been very much *interested in this subject since* my study of the menstrual *changes in the uterine* mucosa, in 1870, and am at present *engaged* in an investigation of the menstrual condition among school and college girls; it has brought to my attention the various forms of dysmenorrhea common among young women in supposedly good health. Dr. Harrison mentioned two forms: one an acute inflammation of the uterine tissue and the other of the appendages. The majority, certainly many, of the cases of dysmenorrhea I observe among school girls are due to nervous influences. I have gone over nearly 5000 cases of menstruation in so-called "well women," girls in educational institutions, neither hospital nor private patients, and find from 42 to 83 per cent., perhaps an average of 66 per cent., afflicted with more or less menstrual suffering. The pain is increased with hours or intensity of study, with worry or emotion, and is diminished or ceases during vacation time without treatment of any kind. These are *nervous menstrual* pains, which are augmented by *physical exertion* and mental application and strain. I believe that the mental or nervous element is a more prominent factor than we usually take it to be, and clearly demonstrates the necessity for a general management of these cases. The character of the pain does not necessarily differ from that which accompanies inflammatory conditions, and how the diagnosis is to be made I do not know, except by examination and study of the individual case, but let us by all means, in the young girl, first attempt the general management, the relief of all abnormal and *injurious* conditions of worry or debility, of mental or physical prostration. As a large majority of these cases are unquestionably due to nervous disturbances, much can be done without local interference. Electricity I have used much and successfully for the relief of menstrual suffering and in the management of pelvic disease, and am sorry to see the contempt with which this really valuable agent is referred to by many and the superficial way in which it is disposed of. I know that many able observers say precisely what Dr. Zinke does. I differ with him, as my own experience is decidedly at variance with his. I like the effect of electricity, but would not rely on its use alone *and unaided* as a means of treatment. It is a valuable and effective agent, but must be used at the proper time, and in suitable cases, precisely as any other remedy or drug. I have found electricity an admirable remedy for *the relief* of pain in cases of inoperable tumors, or when an operation is not desired, in neurotic and neurasthenic cases, in cases where stimulation is needed in debility, local or general, and where thickening of tissue exists, with a want of absorption. Electricity can be applied by a cotton-covered electrode in the vagina as the active pole, and the other over the abdomen, using mild currents. A very satisfactory method in dysmenorrhea due to flexion, narrowing of the canal or chronic inflammation is to use the dilator as an electrode. The dilator is connected with one pole, the abdominal electrode with the other, and the blades gently separated during the séance. In this way the electrode is brought in contact with the tissue, and dilatation is much more easily accomplished with than without the current. It has a relaxing effect and this overcomes the pain of dysmenorrhea. A few applications a month are enough, but most effective is one immediately before the appearance of the flow. The treatment is one requiring time and careful manipulation, with some knowledge of currents and instruments, but it has its good points and I am sorry that men of authority like Dr. Zinke express themselves as he does, as others will be guided by their very positive statements so unfavorable to this agent, which is truly valuable in its proper place, and unjustly abused because enthusiasts have claimed too much for it.

Dr. C. L. Bonifield, Cincinnati, Ohio—Dr. Massey, in his remarks, said, much to my surprise, that those patients where we have a large accumulation of fluid in the uterus suffer no pain. I have seen a number of such following amputation of the cervix, this growing together and the obstruction being absolute or nearly so. They also follow curettement, where proper precautions are not taken to keep the os patulous. It has been my experience that such patients suffer the most intense pain at the menstrual period.

Dr. Herzog's observation that the mucous membrane of the uterus is not thrown off at the menstrual epoch, is the very latest view of German observers on this subject. The pain these patients have may not be due to the difficulty the fluid has in escaping from the uterus, but the difficulty it has in escaping from under the mucous membrane. A fact I have observed, and which speaks for an accumulation of fluid, is that if one of those girls suffering from dysmenorrhea for years, a girl who begins with an undeveloped uterus, be examined under an anesthetic, almost invariably the body of the uterus will be found dilated and pear-shaped. The walls of the uterus are not in contact as they ordinarily are, and one can direct the curette freely within the cavity. Whether this is from an accumulation of secretions or an hypertrophy of the organ I am not prepared to say.

As to electricity, I am willing to grant that Dr. Massey gets the result he claims, and other men who will take the time to learn his methods will get the same good results. I can obtain as good results in other ways that are less objectionable and not so difficult and objectionable. Dysmenorrhea is a disease of the unmarried, and such patients do not like to come to your office to be treated for weeks and months. It is best to dilate the uterine cervix, pack the uterus as firmly as possible with gauze, and thus produce a miniature labor, which will do more good than months of electric treatment.

Dr. F. F. Lawrence, Columbus, Ohio—Some three years ago I wrote a paper on this subject and emphasized the important fact that painful menstruation is not a disease but simply a symptom, and that we should begin the treatment as soon as possible. The conditions giving rise to it must be treated as such, and the symptom of painful menstruation will rapidly disappear with the disappearance of the conditions treated. We might as well talk of leucorrhea as a disease as of dysmenorrhea. I am pleased to note that the doctor makes practically the same statement that I have made in my paper, and that is that obstructive dysmenorrhea has not only been shown to be a mistake, but is something we do not find. The conditions causing the pain may be classified as of uterine, intrauterine, ovarian, tubal, local or general origin, and we must fight the condition itself and treat that condition, and not treat a symptom.

Electricity may be, as Dr. Massey said, of some value: he is competent and we will take his word for it. Is it by its tonic effect, by increasing tissue metamorphosis, or what? Cases of small cervix are usually undeveloped ones. On examination of these—they are usually in young girls—we may find ovaries so small that we can barely tell that they are ovaries. The uterus is completely undeveloped, infantile in fact. These poor girls, suffering frightfully every month, are told that if they will marry they will get well. Cases of hyperemia, if permitted to become chronic, will result in a subsequent destruction of the ovary, and later it will break down into a cyst or become cirrhotic. These latter are the cases which give the most trouble. I have had a number in which a small, hard, cartilaginous ovary was responsible for the most marked disturbance, such as obscure neuralgia, convulsions and other nervous troubles. They are the patients who are not benefited by any local treatment. Many cases of hyperemia treated early will probably be cured by electricity. Of equal benefit are rest, local depletion and abstinence from all things which will produce sexual excitement or physical excesses. We have ovarian, tubo-ovarian, uterine, intrauterine and extrapelvic conditions, which are responsible for this trouble. Our chlorotic girls suffer severely from painful menstruation and nervous disturbances in connection therewith.

Dr. E. G. Zinke, Cincinnati, Ohio—I did not wish to convey the impression that I was opposed to the use of electricity, nor that I condemn any individual who may be disposed to resort to it as a means of treatment. What I did wish to say was this: Our chairman, with his experience, endorsed what I said, that there was no case on record in which the use of electricity produced a cure of any diseased condition of the pelvic organs. It may give relief under certain conditions, although personally I have seen none. No fibroid, ovaritis, salpingitis or endometritis was ever cured by electricity. I know of no man who has more experience, who has investigated more ardently, more diligently, more earnestly than Apostoli, and yet none of his patients, where measurements and plaster casts were taken, was benefited more than temporarily. We never have menstruation without ovulation. We must have had ovulation in order to have menstruation. We may have menstruation after ovulation has ceased, as, for instance, when the menopause has been brought about artificially; but there is no case on record in which menstruation made its appearance when ovulation had never occurred.

Dr. C. C. Thayer—I have nothing to say in regard to my paper, as the points are put there for the consideration of others. The facts are recorded in many of the latest textbooks on the subject, and personally observed in clinical practice. In regard to the use of electricity in dysmenorrhea, I am greatly in favor of it in such cases. I have used it for twenty years, and appreciate its advantages more to-day than ever before. I have no criticism to make of people who have not used it or became familiar with it, but those who have tried it extensively find it to be a wonderful remedy in some patients with dysmenorrhea. Those gentlemen who look for the causes of this affection in the genitalia, do not look far enough. They do not understand the real elements that enter into the condition of dysmenorrhea in many cases, aside from the anatomic derangements or malformation. A most important cause is found in the disturbances of the nervous system, and oftentimes we must begin the treatment of it by directing our attention to general physical conditions. Hygienic treatment is an important item. Along the same line electricity comes in with its influence on the nervous system. It is not so much in dilating the blood-vessels, on which dysmenorrhea is not always dependent, but it is the general tonic effect of electricity. It facilitates free circulation and stimulates the entire nervous system.

So far as accumulation of fluid is concerned, I think that is an exploded theory. I have dilated the uterus time and time again, using the suction syringe to see if there was an accumulation, but found none, and when curetting have found nothing except what was necessarily attached to the mucosa. The accumulation theory is a false one, and in most of these cases I think we will find, as Thomas so beautifully and strikingly showed in his last text-book, "that dysmenorrhea is more often cured by a trip to Europe than by any process or treatment he ever used in his office."

Dr. G. T. Harrison—Dr. Massey can not prove the assertions he made. It is a pity I could not read the whole of my paper, so that you could see the argument. In speaking of Dr. Sims, I think he spoke rather slightingly of him. Of all the names that shine in the pages of the history of our profession, he can not bring forward any two greater names than J. Marion Sims and Carl Schroeder. The latter was one of the greatest and most gifted of modern surgeons. Those who have had the pleasure of seeing him in Berlin were impressed by his greatness, as his was one of the most majestic figures in Germany. As Martin said to a friend, we did not appreciate—fully at first, his loss— and it is only years afterward, after these men are lost to us, that we realize how great their value has been. When I can quote such authorities for the views I hold, I feel that I would rather err with those men than be right with Dr. Massey.

Dr. G. B. Massey, closing the discussion—I do not wish to be behind in my homage to Marion Sims, but the thought occurred to me recently that the day of authorities in medicine had passed away a short time after I graduated. More harm has been done by the blind following of authorities in medicine than by the inquisition of the middle ages. We want facts, not the personality of the man who brings them forward. Sometimes noble personages lead to the perpetuation of great errors. My paper was a very short one and referred only to the incurable sort of cases, those which are supposed to go to the surgeon, hence I welcome the many remarks made about the neurotic cases, those that can be cured without even the means I recommend. I took especial occasion to mention that the uterus should not be invaded by an electrode, or anything else, unless there was local disease of the endometrium. I can not too strongly corroborate the remarks made that needless examination should always be avoided, but there are cases, and I have in my mind quite a number that are destined to shipwreck in life unless they are cured. They come to me before, and they come to me after the dilatation, and it is to those that the second part of my paper particularly refers.

I need hardly say anything on the question of the accepted theory of obstruction. Dr. Bonifield's evidences of pain in connection with accumulation in the uterus were all traumatic. They were operative. You will find in the literature of the non-operative cases of pelvic accumulation that those are not diagnosed until the accumulation will at times amount to a pint of fluid. In other words, the patients have no pain. I have proven, too, that there is no obstruction, that there is no spasm, no actual muscular spasm. I reported a case some years ago, in which I found the cervix more dilated, coincident with the pain, than in the normal condition. After all, the most important element, as pointed out by other speakers, is the neuromuscular storm of the apparatus connected with the reproductive organs, and that explains the pain. It is not the physical obstruction, but it is the painful condition superinduced by the effort of the diseased organ to throw off the immense amount of excrementitious material which is to be thrown off at that time.

MOVABLE KIDNEY, FROM THE STANDPOINT OF THE GENERAL PRACTITIONER.*

ALEX. MARCY, JR., M.D.

RIVERTON, N. J.

Movable kidney was first described by Rayer, in 1836, and since then various authors and writers have called attention time and again to the importance of this abnormal condition, among whom I might mention Hare, Keppler, Sulzer, Hahn, Edebohls, Ewald, Einhorn, Israel, Lewis, Noble, Senn, Keen, Reed, and others. The earlier writers treated it almost entirely from a medical standpoint and the later ones as entirely from the surgical.

My object is primarily to endeavor to interest the general practitioner in the subject, in order that he may be able to diagnose the condition, and to determine which cases should be treated medically and which surgically. I would also like to impress him with the fact that in many cases this condition is a most serious one, and unless it is recognized, and promptly and intelligently dealt with, very grave consequences may result.

The normal location of the kidneys, as well as their anatomical relations to adjacent viscera, are so well understood that I will not take up your time with a description of where they ought to be found, but will try to point out how you may be able to tell when they are in an abnormal position, and outline the symptoms somewhat in detail. The frequency of malposition of the kidney is astonishing, and it has been estimated that one woman out of every four has a movable kidney, and while they are not all of them suffering from it, yet in the vast majority of these cases it does produce symptoms which need attention.

There are probably thousands of women and many men suffering from the effects of a movable kidney to-day, and many of them seriously, who are being treated for indigestion, hysteria, neurasthenia, heart disease—so-called—albuminuria, and even mental disorders, such as hypochondria, melancholia, epilepsy, etc., and who are being drugged almost to death, and yet receive practically no benefit from their treatment. Such a condition of affairs should not exist, and there is no reason why any intelligent practitioner should not be able to recognize and diagnose a movable kidney, if he carefully examines his patient, and after having found it, he should be able to advise the best method for getting relief.

The etiology of this condition is a difficult problem, and the causes assigned by different writers are very many. In some cases it is undoubtedly a congenital condition, but in most of them it is acquired, although I believe that in a very great many there exists an individual predisposition, which is due to some abnormal congenital conditions.

Among the various causes assigned are tight lacing, relaxed abdominal parietes, the result mainly of childbearing, traumatism, and absorption or atrophy of perirenal fat. The last is probably one of the most common causes, as the greater number of cases of movable kidney will be found in thin people; in fact, it is almost axiomatic, given a thin woman, weighing 110 pounds or less, with various reflex nervous symptoms, and you are pretty sure to find a movable kidney.

Movable kidney occurs in the great majority of cases on the right side, and why this is so no satisfactory explanation has as yet been offered. Occasionally it occurs on the left side, and quite frequently both sides are affected at the same time.

The symptoms of movable kidney are very complex, and are common also to many other diseases, particularly those of the female sexual organs. In fact, in very many cases, there is coincident disease of the uterus and its adnexa. The nervous disturbances are greater in the early history of the displacement, and in those cases where the range of motion is not very great, while the localized discomforts are more pronounced where the condition has existed for a longer time, and where the range of motion is greater.

This is probably because the sympathetic nervous system, through the influence of which the various r symptoms manifest themselves, becomes accustomed to the abnormality after a time, and fails to notice it; while, on the other hand, after the condition has existed for a long time, and the range of motion has become greater, we have localized conditions, due to traction on the renal vessels and nerves, congestion and inflammation of the organ itself, and occasionally acute strangulation, due to torsion of the blood-vessels and ureter.

---

* Presented to the Section on Practice of Medicine, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

In the earlier stages, the most common symptoms are digestive disturbances, nausea, epigastric pain, faintness, especially on first arising in the morning, cardiac palpitation, general nervousness, distension of the bowels with gas. These symptoms are aggravated by exercise and excitement. Many patients are unable to ride in steam or trolley cars without being nauseated; later on they complain of localized pain, or a sense of dragging or weight in the lumbar region, and occasionally severe pain, due to extreme congestion or an acute hydronephrosis from twisting of the blood-vessels and ureter.

Inability to lie on the left side is frequently complained of, and the most comfortable position is flat on the back, which position relieves all strain or traction on the blood-vessels and nerves, and permits the organ to resume its normal position and functions.

The diagnosis of movable kidney is comparatively easy. In most cases the patients are thin and the abdominal muscles relaxed, so that the kidney can readily be felt in either the hypochondriac or lumbar region, sometimes as low down as the iliac fossæ. The examination may be made either with the patient lying in the dorsal position, or standing. Personally I prefer the latter, as oftentimes, when the patient is lying on her back, the kidney goes back into its normal position and remains there and can not be felt at all. If examined while in the dorsal position the thighs should be flexed, to relax the abdominal muscles. The examiner sits on the right side of the patient, with his left hand passed under the small of the back, pressing deeply into the renal region, to prevent the kidney from slipping back into position unrecognized. The fingers of the right hand palpating the front and sides of the abdomen usually recognize the displaced organ.

When a movable kidney is discovered, it should be caught between the fingers of both hands and its characteristic shape outlined. Slight pressure will elicit some tenderness, and a peculiar sickening feeling will be complained of. The kidney readily slips from between the fingers back into position, and it is hardly possible to mistake it for anything else.

If the patient is examined in a standing position, she should have her clothing loosened and her skirts supported by a nurse or assistant, or by the examiner himself, so that she will not be embarassed with the fear that her clothing will fall off. She should stand before a table or stand, with her hands resting on it, bending slightly forward. The examiner stands behind the patient, with the thumb of the right hand pressing firmly over the lumbar region, and the fingers pressing deeply in front. The kidney is then felt between the thumb and fingers very plainly, and upon slight pressure slips back into position; oftentimes the patient can distinctly feel it slip from between the fingers and will tell you so.

When the left kidney is examined, the left hand is used in the same way. The advantage of this position is, that very often you wish to examine a patient and there is no nurse or assistant to hold her skirts, and the examiner can hold her skirts with one hand while examining the kidney with the other.

In some cases, where the patient is not very thin, it is necessary to use both hands, and under such circumstances the examiner should sit at the right or left side of the patient, according to which kidney is to be examined, and use the one hand behind and the other in front.

Occasionally the abdominal muscles are so hard and rigid that it is impossible to feel anything. Under such circumstances it may be necessary to administer an anesthetic. Movable kidney must not be confounded with a distended gall-bladder, a displaced liver, or other intra-abdominal tumors. A careful examination of the tumor will easily disclose the characteristic shape and size of the kidney, and the history of the case will, if carefully studied, aid in the differentiation.

The prognosis of movable kidney is favorable if properly treated. There is, however, a very positive danger from such a condition that has been of long standing. The traction on the veins, together with an occasional twist in the blood-vessels and ureter, produces congestion, which is after a time followed by inflammatory changes in the tissues, and eventually you have a chronic interstitial nephritis, manifested by tube-casts and albumin in the urine. Acute hydronephrosis is not uncommon, and this in time may be followed by pyonephrosis. Acute strangulation may also occur with necrosis if it is not promptly relieved.

In all cases the patients are chronic invalids and their lives made very miserable, if not actually shortened, by the neglect to recognize and treat this condition. The treatment may be divided into medical, mechanical and surgical.

1. The medical treatment would consist in the use of such measures as would improve the general health of the patient, together with the accumulation of surplus fat. The rest treatment, with forced feeding and massage is sometimes beneficial, at least temporarily, but as soon as the patient returns to her ordinary duties the condition is, in most cases, reproduced. Toning up the nervous system, as well as the digestive apparatus, relieves the effects of this condition sometimes, but does not alter the conditions themselves, and therefore must of necessity be only temporary. For this purpose, I know of nothing equal to tincture of nux vomica in large doses, together with cold douching of the spine, followed by brisk rubbing.

2. The mechanical treatment consists in the use of elastic bandages, sometimes fitted with a special pad, called a kidney pad, and in some cases this device relieves the symptoms, but I doubt if it ever keeps the kidney in its proper place.

3. The ideal treatment is surgical, and with our improved methods and technique it is attended with a very small mortality, practically none at all when it is not complicated by other abnormal conditions.

This condition is so frequently found in multiparæ and associated with various lesions of the uterus and other pelvic organs that the gynecologist necessarily comes in contact with the greater number of cases, and a number of operations have been devised for its relief.

It is not my purpose to discuss the merits of the different operations, nor to recommend any particular one, but I wish to say that my own cases have always had a nephrorrhaphy done, with buried silk-worm gut sutures, and in every instance the patients have been restored to perfect health and able to perform all the duties required of them in their different stations in life without any difficulty.

To recapitulate, I would like to emphasize the following points: Examine carefully every patient who weighs less than 120 pounds and complains of general nervous symptoms, indigestion, palpitation, etc., for movable kidney. If you do not find it at your first examination, look for it again, and even for the third time, as you will frequently fail to find it at your first examination, and will be able to demonstrate it at your second or third. After having found it, study carefully all the symptoms and conditions and decide what is best to be done. When you have so decided, if you favor surgical treatment and are not qualified to operate yourself call to your assistance some one who is and have him operate for you. As to the particular operation, let the surgeon decide that point and hold him responsible for the results. If I have succeeded in interesting one general practitioner in this important subject, and he goes home inspired with the knowledge that he can bring relief to some of his patients who may have been suffering for a long time from this condition unsuspected then I shall consider my time and effort well spent and shall feel amply repaid for what has been so imperfectly done.

SOME NOTES ON THE CLIMATOLOGY OF ARIZONA.[*]

WILLIAM DUFFIELD, M.D.
PHOENIX, ARIZONA.

It is the purpose of this paper to call your attention to a region about which much has been said and written, and yet concerning which little is known by the medical profession. This lack of knowledge is not limited to the district under consideration and comes through the absence of climatological teaching in our schools and the dearth of literature on subjects pertaining to climate. In the great library of the College of Physicians and Surgeons, in Philadelphia, only one volume on the subject of medical climatology is to be found, and this is really limited in its scope. In about five hundred papers scheduled for this Association only three bear any relation to climate.

Our text-books make reference to the Southwest in a general way in recommending climate for this, that or the other disease, failing frequently to differentiate betwen the climates of this region. The fact is that there are almost as great differences in the climates of the so-called arid Southwest as there are between the climates of the Atlantic seaboard and the Southwest. This paper simply calls attention to the conditions which obtain in Arizona, leaving to the judgment of the practitioner the applicability of the climate to disease.

Arizona is an immense territory on the west of the great Rocky Mountain divide, extending from the northern line of Mexico 400 miles northward, and between California and New Mexico, east and west, about 350 miles.

Solly, in his "Medical Climatology," says: "An inquiry into the climate of Arizona discloses the fact that it is climatically distinct from each of its neighbors, New Mexico and California, and has natural laws of its own, although these laws are modified in turn by the climatic influences of both the Pacific Coast and the Rocky Mountains." He might have added that within Arizona itself almost every physical feature and climatic condition known to any portion of the United States is to be found. The reason for this is found in the physical features of the country and its relation to the Gulf of California and the Pacific Ocean.

For the purpose of the climatologists the territory has been variously subdivided. The classification most commonly given is that of Captain Glassford, namely, a plateau, a pro-plateau and plain. The present section-director of the weather bureau has made a new classification, which seems more satisfactory. That portion of the territory lying west of parallel 113 and extending to California and Nevada he includes in the district which approximates the "plain" of the other classification, and by dividing the remaining eastern portion by the 34th parallel of latitude, he has a northern and southern district, corresponding approximately to the plateau and pro-plateau of Glassford. In two stations of the western division for the year 1898 the mean temperature was 68.9 F. For six stations in the northern division the mean temperature was 52.03. For twenty-two stations in the southern division the mean temperature was 64.01.

On the other hand adopting the classification of plateau, pro-plateau and plain, we find that the plain occupies the southwestern one-third of the territory. The elevation of the plain varies from less than 100 feet above sea-level to about 3000 feet.

Do not get the idea that this is a perfectly level area, for it is not. True it is a plain, but there are mountains and valleys within it, but they are not numerous nor are the elevations great. The soil of this region is largely composed of a rich loam in the valleys, a sandy gravel on the mesas and the usual rocky formations in the elevations. There is very little vegetation except the cactus, sage bush and mesquite, except where irrigation is employed. As the cities which are visited in the winter and spring by thousands of invalids are within the district, making it the most important area from the standpoint of the medical climatologist, we will pause to review the conditions obtaining.

The assertion has been made that the elevation of the plain varies from sea-level to 3000 feet. Taking the only available report from a medium altitude as an average we choose the report from Phoenix for an average year.

For January the monthly mean temperature was 50.4 F., the mean maximum was 63.3 and the mean minimum 37.4. The mean daily range was 25.8 and the greatest daily range 33. The mean variability was 25, the mean of the three consecutive warmest days was 71. The maximum temperature for the month was 73, the lowest maximum was 52 and the highest minimum was 46 F. The mean relative humidity for the month was 49 per cent. The average hourly wind velocity was 3.7 miles. The total precipitation was 1.76 inches, which was 40 per cent. above the average. The percentage of possible sunshine was 85.

By way of comparison the averages at an elevation of 5000 feet in about the same latitude, in the plateau, gave the following: The monthly mean temperature was 41.5, 9 degrees lower. The mean maximum was 53.4, 7.1 degrees lower, the mean minimum was 29.6, being 7.8 degrees lower. The maximum temperature for the month was 66 as against 73 on the plain, and the minimum temperature was 17 as against 29 on the plain. The mean relative humidity for the month was 60.5 as against 19 per cent. The precipitation was 5.4 inches, some 30 per cent. below normal. The percentage of possible sunshine was 65, as against 85 on the plain.

In order to save time and continue the comparison we will take the month of April, the first of the next quarter. The monthly mean temperature was 68.8, the mean maximum 83.8, the mean minimum 53.7, mean daily average range was 30.1 and the daily range 41, the mean variability was 2.6, the mean of the three consecutive warmest days was 93 and the mean of the three coldest days was 47, the maximum temperature for the month was 95 and the minimum 42 degrees. The lowest maximum was 65, and the highest minimum 66 degrees, the mean relative humidity was 28 per cent. The average hourly velocity of the wind was 5 miles. There was only a trace of precipitation. The percentage of possible sunshine was 83. No rainy days were noted.

---

[*] Presented to the Section on Practice of Medicine, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

For this month in the plateau the mean monthly maximum was 79.91, as against 83.8, the mean minimum was 49.2, as against 53.7, the monthly mean was 64.6, as against 68.8 on the plain. The relative humidity was 22 on the plateau and 28 on the plain. The wind velocity of the plateau was 12.6, against 5 on the plain.

Taking July for another comparison, we have a monthly mean on the plain of 91 F., the mean maximum 103.7 and the mean minimum 78.2, the mean daily range was 25.5, the greatest daily range was 32, the mean variability 2.7, the mean of the consecutive warmest days was 109 and the mean of the three consecutive coldest days 70, the maximum for the month was 112 and the minimum was 68. There were 31 days with maximum above 90, 29 days above 95, and 24 days above 100. The lowest maximum was 92 and the highest minimum 84 F. The mean relative humidity was 40 per cent. This is accounted for by the fact that July is the rainy month of this region. The average hourly wind velocity was 4.7. The total precipitation for the month was .87 inches. The percentage of possible sunshine was 78.

For the same month on the plateau the mean maximum temperature was 91.1, as against 103.7, the mean minimum was 68.9, the mean monthly temperature was 80. The relative humidity was 9 per cent. higher than on the plain. The rainfall was 2.89 inches, against .87. The velocity of the wind was 100 per cent. higher than the plain. The percentage of possible sunshine was about 15 per cent. lower on the plateau.

The month of October on the plain was as follows: Monthly mean 68.9, mean maximum 82.1, mean minimum 55.7, mean daily range was 26.7, the maximum temperature for the month was 96, and the minimum 40. The lowest maximum was 66 and the highest minimum was 72. The average hourly wind velocity was 4.3, the mean relative humidity was 40 per cent. The total precipitation was .3 inch. The percentage of possible sunshine was 78.

On the plateau the mean maximum temperature was 76.2, against 82.1, the mean minimum was 49.7, against 55.7, the monthly mean was 63, against 68.9. The humidity was .51, against 40 per cent. The velocity of the wind was 9.8, against 4.3. The percentage of possible sunshine was 66, against 78.

For the year the means were as follows: On the plain the mean monthly temperature 70, mean maximum 84, mean minimum 56. The total precipitation for the year was 5.19 inches. The mean relative humidity was 36. There were 245 absolutely clear days in the year, 86 partly cloudy, and 34 cloudy. The percentage of possible sunshine was 85. The average hourly velocity of the wind was 4.4 miles.

On the plateau the means were as follows: Mean monthly temperature 48.2, mean maximum 58.5, mean minimum 37.6. The total precipitation was 19.6 inches. The mean relative humidity was 52. There were 180 clear days, 149 partly cloudy, and 36 cloudy. The percentage of possible sunshine was 65. The average hourly velocity of the wind was 7.1.

Thus it is seen that Arizona presents a great diversity of climates within her own borders, varying from the subtropical to the almost perpetual snow on the peaks of the high mountains of the north. Yet there is a marked similarity in all portions in the essentials of a dry climate, namely, the low relative humidity and the high percentage of possible sunshine. No region in the United States, and perhaps in the world, equals or even approximates the southwestern plain of Arizona for the dryness of atmosphere, the days of sunshine and low velocity of the wind. As in all dry climates, there is a marked difference between shade and sunshine, day and night, but it is a difference which is regular and constant, and can be guarded against by the invalid, because it can be anticipated.

Furthermore, Arizona offers any altitude from sea-level to 13,000 feet, and she has mineral and thermal springs whose virtues are just beginning to attract attention. If a maximum of sunshine, a minimum of moisture, with the ability to live out of doors in any elevation desired, meets the requirements of the medical profession of America, Arizona presents claims which demand consideration.

PREVENTIVE TREATMENT OF MIGRAINE.*

E. W. MITCHELL, M.D.

Professor of Materia Medica and Therapeutics, Miami Medical College; Physician to Cincinnati Hospital.

CINCINNATI, OHIO.

The explanation of numerous diseased conditions on the theory of autointoxication has found ready acceptance because of its simplicity and because of much apparent evidence in its favor. This has been an especially welcome hypothesis to account for that obscure group of diseases known as the neuroses, for which all other theories have been so unsatisfactory. In this group it has been common to include migraine. Theoretical considerations, clinical observations and therapeutic results all point strongly in favor of such a hypothesis. But, however simple this theory seems in its statement, it in fact only throws the mystery a step further back. It is an explanation which needs explaining. It opens questions which involve the most complex problems of physiological chemistry. What are the toxic substances? Where and how are they formed? What organs are involved? These and many other questions have not yet been solved, and probably will not be for a long time. This is about the conclusion to which Ewald[1] comes in his recent elaborate review of the subject, which is the best summary of our present knowledge that has been published.

Bouchard's well-known work will remain one of great value, although all of his conclusions are not accepted, as will also the work of Alexander Haig on uric acid. How thoroughly the uric-acid theory has taken hold of the professional mind is evidenced in the frequency with which we find recurring in the medical literature of the past fifteen years the terms "lithemia," "uric-acid diathesis," "uricemia," etc.

As to migraine and similar disorders, Haig's results have been confirmed in so far as the increase of uric acid in the blood preceding the attacks is concerned, and as to the fact that preventing the increase of uric acid usually prevents the attacks. However, it has never been accepted that uric acid alone was the noxious agent.

---

* Presented to the Section on Materia Medica, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

[1] Berlin. klin. Wochensch., Feb. 12 and 19, 1900.

The discovery of ptomains and leucomains raised the presumption that some of these bodies, particularly the leucomains, might be the real causative agents, especially when it was found that the symptoms produced by the injection of these substances into animals closely resembled the symptoms of some of these diseases. As the leucomains may be supposed to fluctuate along with the uric acid in the metabolic changes of the body, we have in this supposition supplied exactly what has been wanting as a causal factor.

About 1895 I became interested in the investigations my fellow townsman, Dr. B. K. Rachford, was making along this line. He apparently demonstrated the presence of paraxanthin in excess in the urine following attacks of migraine and migrainous epilepsy.[2]

Not only did his experiments seem to be conclusive, but the results of treatment on the lines thus indicated seemed to confirm it. Unfortunately other experimenters have not been able to confirm Dr. Rachford's results. Dr. Pfaff,[3] of Boston, has failed to find paraxanthin in the urine in such cases. Drs. Forcheimer and Stewart have apparently shown that the toxic properties of urine are due to bacteriological growth after it has passed, and that urine, either from a normal or migrainous subject, which is kept sterile is not toxic. These results throw considerable doubt on the reliability of Dr. Rachford's results, so that we must admit that however attractive and however probable, they are as yet not demonstrated.

To us, as therapists, the result of treatment is the main question, and here, as elsewhere, our therapy may be in advance of [illegible] though I can not be sure of Dr. [illegible], I have had in cases of typical migraine great satisfaction in following his plan of preventive treatment as given in his various papers published in the *Medical News* and *Archives of Pediatrics.*

In its essentials this treatment, it is true, is not original. Since Haig's book appeared in 1892, I had, with fair success, followed his treatment of exclusion of meat diet, the administration of salicylates and other drugs which favor the elimination of uric acid; but my success has been much better in thoroughly carrying out the treatment of Dr. Rachford.

It must not be forgotten that, notwithstanding some form of leucomain poisoning may be the efficient cause, those concomitant causes which are enumerated in the text-books under etiology should not be neglected. Perhaps the most important of these is eye-strain. So frequently is this found that some writers have been inclined to make it the chief pathological factor.[4]

But the correction of ocular defects does not always cure without further treatment. Uterine and menstrual disorders must have appropriate attention. In children, adenoid growths should be removed. Vicious habits and hygienic sins must be corrected. Some of the French writers have ascribed an important rôle to dilatation of the stomach and proptosis of the abdominal organs in the production of sick headache. By favoring fermentation and absorption they may be predisposing causes when present. One such case has come under my care.

Case 1.—Mrs. J. W., aged 41 years, widow, mother of two living children, of lithemic diathesis and with lithemic family history. General health is excellent; she has severe headaches recurring every ten or twelve days, accompanied by nausea and vomiting, with dizziness and flashes of light before the eyes. Pain is worst on right side, but radiates over whole head; has some fermentative dyspepsia with coated tongue, eructations, etc. Bowels constipated, urine somewhat scant and high colored. Has been subject to migraine nearly all her life. Physical examination negative, excepting relaxed abdominal walls with descent of stomach, lower margin of which is one inch below the umbilicus. An abdominal bandage was ordered; daily lavage was made for two weeks, then tube used only when symptoms of gastric fermentation returned or a headache threatened. Meat was excluded from the diet; the constipation corrected; lithia water given freely; exercise in open air ordered.

There was an immediate improvement, the headaches recurring only with some violation or neglect of instructions. Since the migraine had existed prior to a time that it was likely her proptosis began, for there was a distinct tendency to lithemia, it is not likely that the proptosis was more than a minor causal factor. My observations have convinced me that the essential in preventive treatment is the withdrawal of the red meats from the diet. At the beginning this is a hardship for many patients, but after a time they lose the craving for meat and very willingly avoid it. The hearty co-operation of the patient is essential for success. I am accustomed to say to such patients: "Your headaches are due to a constitutional tendency which can not be removed, but you may have your choice of suffering or being practically free from them by practicing self-denial and following certain rules." This plan of treatment is briefly as follows:

1. Red meats are to be rigidly excluded; fish, bacon, brains, sweet-breads and eggs are allowed. Rich and highly-spiced dishes are to be avoided. Coffee, tea and alcoholic beverages are to be excluded. Sweets should be reduced, but when meats are excluded a moderate amount is well borne. Water may be taken very freely. Meals to be taken at regular intervals and overloading of the stomach to be avoided.

2. As much outdoor exercise is to be taken as possible—undue fatigue to be avoided—rooms always should be well ventilated, both by day and night; and hot baths taken two or three times a week. In some cases the Turkish bath is beneficial; in some cases the morning cold sponge bath is directed.

3. The medicinal treatment aims to regulate the bowels, to promote intestinal antisepsis and to stimulate the liver, the great organ for completing the oxidation of the products of metabolism, and protecting the body from poisoning. The same end may be attained by various means. The various salicylates are all useful. In obstinate cases an occasional mercurial is required. I have had the best result in the long-continued use of some of the formulæ recommended by Dr. Rachford.[5] The one most commonly used is as follows: sodii sulph. (crystals), 120 grains; sodii phosphat., 30 grains; sodii salicylat., 10 grains; tinct. nucis vom., 3 drops; aquæ dest., to make 4 ounces. This dose is to be taken before breakfast each morning and is best taken in a glass of seltzer, or still better the ingredients are made up in these proportions in large siphon bottles charged with carbonic acid. The proportions are variously modified in different cases. In my own case I have so far seen no benefit from the use of potassium permanganate, which Dr. Rachford frequently uses.

[5] Archives of Pediatrics, Oct., 1897.

From a number of cases which have been kept free or nearly free from suffering for a long time I select the following:

Case 2.—Mrs. C. E. S., aged 42, large and fleshy, of indolent habits, has been subject to sick headaches since puberty, general health is good. She came under treatment in April, 1898, at which time she was having an attack of typical migraine every two weeks, of great severity. After ruling out ocular defects and other sources of reflex disturbance she was put on the course of treatment above outlined. The above mixture in siphon she took each morning for several months, and still takes it for a few days or weeks if she becomes constipated or is threatened with a return of headache. The headaches disappeared almost immediately after beginning the treatment, and now recur very rarely and only when she breaks some of her rules.

Case 3.—Robert S., aged 9 years. In early childhood, as nearly as his mother can recall, when between 2 and 3 years old, he began to have paroxysmal attacks of vomiting with severe headache and great prostration. He continued to have these attacks every two or three months with occasional milder attacks between. In the severe attacks he became unconscious, with head strongly retracted, with pupils contracted. On several occasions physicians who saw him believed that he was developing meningitis. All treatment had failed to do more than mitigate the attacks. He was very fond of meat, and it was quite a struggle for him to give it up. However, he very manfully submitted to the ordeal and was rewarded by almost complete relief for the past year and a half. He is allowed to have a little chicken occasionally. He now cares so little for butchers' meat that he does not eat it if placed before him. He has grown stronger and more robust. The oculist's report in this case was negative. He took a mixture of salicylate, phosphate and sulphate of soda before breakfast for one year, and still occasionally takes it.

In two other school children of about the same age I have had the same result, except that in one but little benefit was derived until errors of refraction had been corrected, and the third had constant relapses, from failure to follow the treatment, although quite free when closely adhering to it.

Case 4.—Mrs. G. D., aged 37, has family history of gout and rheumatism, is subject to rheumatism and neuralgia, has severe headaches just preceding each menstrual period, with extreme nausea and vomiting. The pain is supraorbital and on the right side. She is also subject to headaches which are not migrainous in character. She has astigmatism and myopia. She has also had pelvic inflammation leaving retroversion and adhesions. As her reflex disturbances can not all be removed and as the pelvic conditions do not allow vigorous exercise the result of treatment has not been entirely successful in her case. However, her attacks have been so greatly mitigated in severity and diminished in frequency that she very gladly adheres to the main outlines of this plan of treatment and most of the time has a siphon of the saline mixture on hand.

These are but a few cases chosen to illustrate the general outline and general principles of treatment of a large class of people, many of whom had life made miserable by the constant recurrence of their attacks of sick headache.

DISCUSSION.

Dr. Heinrich Stern, New York City.—The medical men of this country should be thankful to Dr. Rachford, of Cincinnati, Ohio, for pointing out that paraxanthin, which is the urotheobromin of the older experimenters, is found in increased quantities in the urine of persons who have been subjected prior to the enlarged excretion of this substance to an epileptic attack. Migraine possesses an epileptiform character, and I have found, repeatedly, a greatly increased output of this dimethyl-xanthin body in the urine of patients habitually suffering from migraine. Paraxanthin melts at 295-296 C., and forms glistening plates often 4 mm. broad. It crystallizes occasionally in needle-form crystals. It is hardly soluble in cold water. In hot alcohol it dissolves readily. Its solutions react neutral.

The methods employed by Bouchard in his experiments are irrational, imperfect and in a measure nonsensical. As I stated some years ago—Recent Studies in Urinology—there are mainly two objections to the experiments alluded to by Dr. Mitchell: 1. The direct introduction of the urine of man into the circulation of the rabbit. 2. The application of the phenomenon thus produced toward forming conclusions as to the autogenesis of certain diseases in man. The poisonousness of the renal secretion, I contend, may depend on certain elements which are not preformed in the blood, and which are transmitted into the urine from another source.

I am sorry that the time allowed for discussion does not permit of going at greater length into Bouchard's experimental fallacies and subsequent irrational conclusions. We American physicians have no business whatsoever to accept every new fad in medicine on account of its newness or because it is imported.

The red meat, chemically speaking, does not seem to differ materially from the white meats. The xanthin bodies are contained in the white meats in about the same quantities as in the red. Birds excrete enormous quantities of uric acid. This substance is contained in goodly quantities in the liver and muscles of geese, turkeys and other poultry. Most flesh of poultry is classified as "white meat," but it certainly contains all or nearly all these substances which we wish to keep out of the organism, when we prescribe a diet without "red meat."

Dr. J. H. Yarnall, Washington, D. C., said that he has all his life been a great sufferer from migraine. His diet has consisted almost exclusively of red meats, never having eaten but one vegetable. He has at different times tried strict dieting, abstaining from meats and living on milk, eggs and dried bread without noting any difference in the frequency or severity of the attacks. The treatment that affords him the most relief is perfect rest; as soon as he notices the scintillating sparks appear before his eyes in the premonitory stage, he goes, if he can, into a darkened room and lies down, takes a small amount of whisky, and remains perfectly quiet; he generally gets over an attack in this way in an hour, but if the circumstances are such that he can not do this at once, the acute attack ensues with the most intense headache, the pain being of such a piercing character that he has had to take a small dose of morphia for relief. This treatment is only palliative, and has no effect in diminishing the frequency of the attacks. His experience has been that there is no distinct line of treatment that will suit all cases, but that each must be studied and treated on its own merits.

Dr. A. L. Benedict, Buffalo, N. Y.—What is most needed in a discussion of this topic is an agreement as to what is meant by migraine. Oculists say that it is a headache due to eyestrain; some clinicians say that it is a gastric reflex; others go so far as to declare that it is essentially gouty. If asked just what they mean by "gouty migraine," they will answer that it depends on an intestinal indigestion. If we question further as to the nature of the failure of intestinal function, we meet with no satisfactory explanation. In some instances migraine seems to be the expression of a bacterial development in the lower bowel. In such cases great relief may be obtained from thorough flushing of the bowels, both by the rectum and through the mouth. In the use of colonic lavage, we must be careful to avoid the time of gastric digestion, for the reasons pointed out by Dr. Fenton B. Turck, of Chicago.

Many of these cases of so-called migraine are due to deficient secretion of hydrochloric acid, and are best treated by the administration of this acid. I wish to emphasize this point because so many physicians, relying on the sourness of which patients complain, fall into the error of considering the condition one of superacidity. In a sense, it is superacidity, but of an organic kind and best combated by hydrochloric acid, though alkalies will give immediate relief. I admit the possibility of mirgaine due to hyperchlorhydria, but, in my experience, this symptom is very rare in patients who have an excess of hydrochloric acidity.

Dietetic causes are certainly operative, but I believe that the essayist has too severely condemned sugar and candy. Most of us, at least in America, eat about three times as much meat as we should. I do not mean this as a general statement, but as one representing an actual, though approximate, arithmetic calculation. If we estimate the amount of proteid contained in bread-stuffs, vegetables, eggs and milk, we shall find a very small amount left to be provided in the form of meat. The ordinary serving of meat at a first-class restaurant is considerably more than should be taken in the course of an entire day. If we eat more than one meat or fish course, or if, as most of us do, we eat meat, hot or cold, fresh or preserved, at every meal, we exceed the normal ration at least twice. Now, with this excessive diet of proteid and of proteid rich in extractive, that is excrementitious, matters, if we take two or three pieces of candy and have a headache, the average layman, as well as the average physician, ignores the meat and lays the entire blame on the sugar. Very few of us are using muscles or wearing out our brains to such a degree as to need very much reparative material, and this is the sole physiologic function of proteid, although it may, in an emergency such as diabetes furnishes, be employed as a producer of heat and force. Sugar, on the other hand, is a valuable and concentrated fuel-food. All carbohydrates are digested into glucose before being of use to the body, and we have a special intestinal ferment to split into glucose, the three double hexoses, milk-sugar, maltose and cane-sugar. In many cases of migraine we find an excess of indican in the urine and an excessive virulence of the colon bacillus, due to the presence of an excess of undigested but rotting proteid. It certainly is a mistake to incriminate sugar and candy in such cases, though their excessive use may aggravate the essential condition.

Dr. J. N. Upshur, Richmond, Va., wished to refer particularly to the use of red meat and the supposed lithemic cause of migraine. He thought, after reading Haig's book, that Haig has a hobby and rode it, booted and spurred, for all it was worth. The speaker had seen many cases of migraine, in which it would not apply, cases of headache from other causes beside digestive disturbance. Many of his patients presented symptoms of overwork of the nervous system, one of the first symptoms of breaking down in some of these was the failure of digestion, but not from any dietetic cause. There is probably in many of these an accumulation of uric acid in the emunctories of the body, as the result of disturbance incident to nerve strain. Like the gentleman from Washington, he had himself personally suffered from migraine, but in his case it was a condition of lithemia due to overwork. The attacks were associated with intense pain in the colon; requiring several weeks to break it off by careful treatment. Patients may suffer from migraine without committing any errors of diet, but as the direct result of overwork and nervous strain. There is a prominent member of the Association, a tireless worker, who, finding himself suffering with lithemia, followed out the plan of Haig, although he was the smallest eater of any man the speaker had ever seen. He did not need to be dieted, but did require a careful building-up treatment. The result of following out this plan of Haig's treatment in this case has been most unfortunate, and the distinguished patient is practically "laid on the shelf" in the midst of his usefulness. We do not yet know the pathology of gout and lithemia. The speaker noted a distinction between gout and lithemia. In a case of gout we have a history of a man who eats heartily and takes his bottle of Burgundy and goes to bed, feeling very contented with himself and the world, but wakes up at 2 o'clock in the morning, feeling as if a blacksmith had his toes in a vise. The next day he feels well and does it all over again. That is the result of indulgence in the pleasures of the table and is common in England. In this country, on the contrary, we make eating entirely a secondary consideration. A man here usually will only take twenty to thirty minutes for his meals, and really does not give enough attention to the subject. Personally he is a very small eater and cares little for food, but lives under constant strain and pressure, and from this overstrain of the nervous system he has a condition, from time to time, of something which he calls lithemia, although he does not know whether it is uric acid or some other error of metabolism. In the treatment, however, some action must be had upon elimination, either by the kidneys or the liver, in order to overcome it; and until evidence is obtained of proper secretion of bile from the liver, all other remedies will be of no effect. You must use one of the mercurials and follow this up with phosphate of sodium, which is the best solvent of uric acid that we can have. He gives it in hot water several times a day, until full action is obtained and then he follows it up with salicylate of sodium. Some physicians prefer salol, which is the most infamous concoction that has ever been introduced. A man does not want to put into his stomach anything that, for several days after taking it, will make him feel as if he had a hornet's nest in his stomach, from the eructations of gas. The principal thing is to relieve the nerve-strain. What the condition needs is rest, not dieting but every patient must be treated according to his individual merits, by taking away the red meats in some cases, while others needing nourishment are allowed the red meats in moderate quantity with other food. In most cases, the best nourishment is plenty of fresh milk.

Dr. J. M. Allen, Liberty, Mo., said he had noticed that in regard to migraine, or old-fashioned sick headache, it subsides if the patient lives to be 55 or 60 years of age. The pathology of migraine is unsettled. It commences with pain in the head and is followed by nausea. Is the nausea due to the headache, or is it due to reflex, or other causes? In some cases it is observed that the stomach is intensely acid, and the intensely acid fluid passes through the pylorus. When there is not enough alkali there to overcome this acid condition of the contents of the intestine, in order to produce the necessary digestive changes, the result is interference with metabolic processes. The next phenomenon noticed is an increased flow of urine. As a result of the faulty metabolism, we have some noxious substance present in the blood, and this is thrown off in a large flow of urine. Some say there is deficient action of the liver. If there is any way of discovering when the liver does not secrete bile, he would like to know it. The liver keeps right on secreting bile. When the stools are pale, it is because the biliary ducts are obstructed, and all cholagogue remedies do harm. Moreover, the retained bile can not be the cause, for we know that just where biliousness should be expected in catarrhal jaundice, where there is no obstruction of the gall-ducts and the white stools, these symptoms are absent.

Dr. E. H. Bartley, New York City, said that he would like to harmonize the various conflicting theories which had been mentioned with regard to the pathology of migraine. The accumulation of uric acid has been blamed by some; others hold that the digestive disorder is the principal factor, and others believe nervous disturbance to be at the bottom of the matter. Each view is partly right. There is impairment of digestive processes, but the nervous strain leads up to the digestive disturbance and the lithemia. The nervous strain is not the direct cause of the lithemia, but leads up to it. It must be remembered that Haig's method does not distinguish between uric acid and the xanthin bodies, so when Haig says uric acid, he means uric acid plus the xanthin group of bodies to which reference has been made by Dr. Stern. There is one point in diagnosis that is important. Where the nausea precedes the headache, it is usually a case of migraine due to stomach disorder, but where the headache comes on first it is likely to be one of nervous origin, often due to eye-strain. With regard to the cure of the patient, we can get the attacks to come a month or two months apart, or even at longer intervals, but in a patient with this tendency to migraine, he can not always expect to get entirely rid of the headaches, and he should be told this so as not to expect too much from the treatment.

Dr. E. W. Mitchell, in closing, said that in his paper he had spoken only of typical cases of migraine. In the discussion he had not heard anything to disprove the fact that the xanthin or alloxuric bodies are not present in the urine. While we may not accept the work of Haig to the full extent, yet it clears up the subject. It is quite probable that varying symptoms may depend on varying amounts of these partially changed bodies being carried over and not burned up. It is likely that the liver is the organ which has the function of converting these bodies. So we come back to the former views as to biliousness and inactive liver, but we have a more scientific view as to what is meant and how the liver may be at fault. The essential point in the treatment is not one remedy, or single combination of remedies, but following out the plans of treatment indicated, which he had adopted with such success that he felt warranted in bringing it before the Section. In some cases, meats can be withdrawn and eggs substituted; he also recommended to his patients to use brown and particularly corn bread instead of white. In regard to the discussion about the red and the white meats, there is a difference independently of the question of the proteids. He considers the white meat more easily digestible. Where there is disturbance due to bacteria, it would be advisable not to use meat at all. In the laboratory we use meat broths for making cultures of virulent bacteria, and perhaps their use might favor such infection in the bowel.

CASES ILLUSTRATING VALUE OF RECTAL INJECTIONS OF SALT SOLUTION IN HEMORRHAGE AND THREATENED COLLAPSE

T. B. GREENLEY, M.D.
MEADOW LAWN, KY.

On Sept. 16, 1899, I was called to see a woman suffering from hemorrhage due to abortion, at the end of the second month. She was virtually in a state of collapse, being pulseless and very pallid. I gave, hypodermically, nitroglycerin and atropin, near the shoulder.

Then, as soon as I could have it prepared, I injected nearly a half-gallon of hot salt solution into the bowel and held it there by pressure on the anus for one-half hour; her pulse came up, and she resumed to some extent, her natural color. I then put her on turpentine and ergot every two hours.

There was no more hemorrhage. The entire ovum was expelled, and there being no placenta I did not, in her prostrated condition, examine for clots. I saw her the next day, and found her doing well, with no further hemorrhage.

Case 2.— On the night of Nov. 3, 1899, I was hurriedly called to see Mrs. R. She was supposed to be in the third month of her pregnancy. She was flooding freely; a large pool of blood was on the floor, having passed through the bedding. She was nearly pulseless, her heart beating very feebly. I could feel a vibration of the radial artery, at the wrist. I used the same treatment in this case as in the first, and, in addition, washed out the womb with hot water, and removed the remaining clots with my fingers. She rallied in less than an hour, when the hemorrhage was completely arrested. I put her on turpentine and ergot, as in the first case.

Case 3.—This was a neglected case of cholera infantum in a child of eight months. It had vomited and purged nearly three days when I saw it, and was nearly exhausted. The small vibration of pulse at the wrist could not be counted. It had kept food on its stomach only a few minutes at a time since it had been taken sick. It was very restless, and reached and cried for anything in a glass or cup, from intense thirst.

I injected about 1/40 grain of morphin with a minute portion of atropia, in its arm; as soon as I could have the salt solution prepared, I injected nearly a pint into the bowels, retaining it by pressure. In less than an hour its pulse came up, and it became quiet. I then allowed a teaspoonful of milk every fifteen minutes. It ceased vomiting, and in a few days, under proper treatment, was restored to health.

It is astonishing with what rapidity the sigmoid flexure and colon can absorb fluids in conditions where the blood-vessels are virtually empty, as illustrated in the above cases. It seems to me that this would be a better, if not a quicker, mode of introducing salt solution into the system than by hypodermic injections, likewise less painful to the patient and less dangerous than transfusion. In cases of emergency, like those above related, it is essential to get the fluid into the circulation as quickly as possible; it can be done by enema much sooner than we can get ready to do it by either of the other modes.

Another advantage is that the sterilization of instruments is not necessary; no time is lost thereby. We require only a fountain syringe, and in its absence a common hand syringe will answer the purpose. The salt solution should be sufficiently warm, about 110 to 115 F., and of the strength of an ounce of sodium chlorid to the gallon of water.

In using the hypodermic injections, we have to be prepared with the proper size of needle, which should be sterilized before using. This operation should be only done by the physician. Transfusion is attended with more risk to the patient and should only be done by the most careful and painstaking physician, and in fact it would always be advisable, when this operation is performed to have consultation.

In cases of emergency, like those above related, we have not time to send for instruments or medical assistance. Therefore, we contend that the quickest and safest plan, in such cases, is the best.

Salt solution is not only used as the proper fluid to restore the lost volume of blood to the system, but is also regarded as an effective antiseptic.

DISCUSSION.

Dr. J. M. Allen, Liberty, Mo., approved of the teaching of the paper, which was on a comparatively new subject. Not every physician is in a position to transfuse blood, but rectal injections of normal salt solution can be practiced by every one. The one great difficulty experienced is in getting the fluid to rise above the sigmoid flexure. His own plan has been to raise the hips of his patient by allowing him to lie across, and partly over, the bed, with his shoulders near the floor. By this expedient the injection is very easily introduced and retained. With the aid of ergot to constrict the tissues and strychnin to overcome the anemic condition of the brain, and the use of this method, he does not see that it is necessary to lose a single case of this character. Time is what is wanted, and only a short time, and this expedient keeps the patient up until the blood-vessels are again fully supplied with blood.

Dr. J. Tracy Melvin, Saguache, Colo.—In the treatment of cholera infantum, there is one fact which must impress itself on every practitioner, i. e., that the saline injection is the one remedy for the relief of genuine cholera infantum. There is generally too much time lost in trying other remedies. If the author of the paper can persuade other physicians to overcome the collapse not only of hemorrhage, but also of cholera infantum, by saline injections, he will render valuable service and save many lives.

Dr. T. B. Greenley, in closing, said that the first time he used the normal salt solution this way was in a case of collapse following postpartum hemorrhage. It occurred to him that if he could by any means fill up the blood-vessels, he might overcome the collapse. He made the experiment of injecting the saline solution into the bowels; the patient soon afterward came out of the collapse and made a good recovery.

PHYSIOLOGIC RESUSCITATION OF THE STILL-BORN.*

DANIEL LICHTY, M.D.
ROCKFORD, ILL.

The usual methods of resuscitation recommended and practiced are so illy applicable at the bedside, to the restoration of the still-born, and so often ineffectual, that the suggestions here given and employed during eight years of the usual obstetric service of the general practitioner are deemed worthy of presentation.

The bronchi, bronchioles, rings, alveoli, sera, epithelia, mucosa, capillaries, elastic connective-tissue and muscular fiber of the lungs form an aggregation of structure as interesting and complex, regardless of their nervous control, as any in the human body.

Bearing in mind that the lungs do not functionate at all as organs during intrauterine life, but simply vegetate through their nutritive channels; and that the rich and active plexus of vessels of the pulmonary circuit are not employed during this period; and that the resiliency of the pulmonary tissues has not yet been tested, nor have the chest muscles been used in the mechanism of respiration, it becomes more apparent that physiologic rather than mechanical methods should be sought and employed to induce function.

During fetal life the respiratory center is in physiologic desuetude, or in an apneic condition; but there remains unleashed a negative pressure-of-inspiration in the nerve-cells of this center which is an inherent or latent potentiality, which keeps up a physiologic, coordinated, rhythmic relation with the circulatory center through their inosculating branches as long as life exists. Fetal blood has a larger percentage of hemoglobin than the mother's, and has also a larger respiratory capacity than adult blood; hence there is a remarkable power of resisting asphyxia in newly-born animals that have never breathed[1]. This was noted as early as Haller's period, and has since been made a subject of further experiment by Buffon, Langollois, Rosenthal, Stokes, W. F. Edwards and others.

Animals that are born with their eyes shut, as dogs and cats, and which have at first very little animal heat, will show signs of life after complete submersion for more than a half-hour in warm media; on the contrary, if a hibernating animal is put in a temperature of about 10 F. below zero, it dies through a paralysis, or inhibition of the center of respiration; but when these same animals are enveloped in an atmosphere or medium of greater temperature than found in either at birth or at apnea, respiration is soon established[2], even to a degree of excessive depth and frequency. And again, Dr. Ackerman has stated that the frequency of respiration is caused by neither want of oxygen nor excess of carbon dioxid in the blood, but alone by the increase of temperature of the whole organism, or heat dyspnea, or what Dr. Isaac Ott calls polypnea.

That there is an anatomic and physiologic area or center in the medulla oblongata which is recognized as presiding over respiration is no longer a subject of doubt or discussion. Experiment has been often enough duplicated to prove that removal of or injury to the medulla oblongata, alone, at once stops all respiratory movements, even though all the muscles of the trunk concerned in respiration—and they are many—and their associated nerves be left entirely uninjured; or, if that smaller tract of the medulla whose limits are not as yet exactly defined, lying below the vasomotor center, between it and the calamus scriptorius, be crushed or removed, respiration ceases though every other part of the body be left intact; so near this is the inhibitory vagus center that it too is generally injured or irritated and the heart's beat arrested or impeded, instant death ensuing.

This very important portion of the nervous system was designated by Flourens, the "vital knot," or ganglion of life; it is now, I believe, generally recognized by physiologists as one of the respiratory centers[3].

The group of dynamics stored in these centers coordinating respiration, is very complex and of wide distribution, as evidenced in impending asphyxia, dyspnea or aroused respiration, when nearly all the muscles of the trunk are called into requisition, reinforced by the rigid extremities fixing the trunk as auxiliaries.

Isaac Ott's polypneic center seems so firmly established that its recognition in this connection confirms the practice to be recommended: he locates this center in the tuber cinereum, and demonstrates that external heat as an irritant to the cutaneous surface carries an excitant to the polypneic center which, acting as a reflex center, sends other impulses that are carried to the adjoining respiratory centers, causing rapid respiration; he asserts that heat is the best external stimulant to rouse the polypneic center—the center of respiration in cases of poisoning or drowning.

Then we have Christiani's expiration and inspiration centers, Martin and Booker's inspiration center in the posterior bodies of the corpora quadrigemina; and Ott's polypneic center; all these subsidiary ones are in the medullary center and through this depot exert their influence on respiratory movements; these subsidiary or subordinate centers are no doubt connected with each other and with the vital center by well-fixed and responsive nerve-paths. It would be a waste of time to rehearse the experiments made in this field of research[4], while the clinical evidence that confirms the existence of such a depot is not rare; and the interrelation of function, physiologic and pathologic, between this and the ganglia of the great sympathetic, or organic brain, adds strength to the position.

"We also know that many cases of head injury by accident, or during delivery at child-birth, appear to end fatally, owing to failure of the respiratory center; in these cases alternate heat and cold to the abdomen and chest tide the patient over this dangerous period and bring about an ultimate recovery."[5] There is no doubt that most of the cases of asphyxia neonatorum are caused by pressure on the occiput during emergence beneath the symphysis and are a traumatism as much as if occurring in an ordinary accident.

Every ultimate structure has its center and its periphery, whatever its shape; the nucleus, nucleoli, surrounding fluid and hyaline wall form an arrangement by which excitation of any part of its peripheral wall finds an active response at its center; the human organism is an aggregation of these mobile, plastic and responsive units of which the new-born is its most delicate expression; the dynamic forces given by the gestative impress are inherent in all the structures; it is our duty to recognize these anatomic structures and physiologic processes in the methods of the resuscitation of the still-born. We know that the syncope occurring in chloroform employed as an anesthetic, induces primary failure of the circulatory mechanism and secondary failure of the respiratory center; the latter fails to act not converting these bodies. So we come back to the former views as to biliousness and inactive liver, but we have a more scientific view as to what is meant and how the liver may be at fault. The essential point in the treatment is not one remedy, or single combination of remedies, but following out the plans of treatment indicated, which he had adopted with such success that he felt warranted in bringing it before the Section. In some cases, meats can be withdrawn and eggs substituted; he also recommended to his patients to use brown and particularly corn bread instead of white. In regard to the discussion about the red and the white meats, there is a difference independently of the question of the proteids. He considers the white meat more easily digestible. Where there is disturbance due to bacteria, it would be advisable not to use meat at all. In the laboratory we use meat broths for making cultures of virulent bacteria, and perhaps their use might favor such infection in the bowel.

PHYSIOLOGIC RESUSCITATION OF THE STILL-BORN.*

DANIEL LICHTY, M.D.
ROCKFORD, ILL.

The usual methods of resuscitation recommended and practiced are so illy applicable at the bedside, to the restoration of the still-born, and so often ineffectual, that the suggestions here given and employed during eight years of the usual obstetric service of the general practitioner are deemed worthy of presentation.

The bronchi, bronchioles, rings, alveoli, sera, epithelia, mucosa, capillaries, elastic connective-tissue and muscular fiber of the lungs form an aggregation of structure as interesting and complex, regardless of their nervous control, as any in the human body.

Bearing in mind that the lungs do not functionate at all as organs during intrauterine life, but simply vegetate through their nutritive channels; and that the rich and active plexus of vessels of the pulmonary circuit are not employed during this period; and that the resiliency of the pulmonary tissues has not yet been tested, nor have the chest muscles been used in the mechanism of respiration, it becomes more apparent that physiologic rather than mechanical methods should be sought and employed to induce function.

During fetal life the respiratory center is in physiologic desuetude, or in an apneic condition; but there remains unleashed a negative pressure-of-inspiration in the nerve-cells of this center which is an inherent or latent potentiality, which keeps up a physiologic, coordinated, rhythmic relation with the circulatory center through their inosculating branches as long as life exists. Fetal blood has a larger percentage of hemoglobin than the mother's, and has also a larger respiratory capacity than adult blood; hence there is a remarkable power of resisting asphyxia in newly-born animals that have never breathed[1]. This was noted as early as Haller's period, and has since been made a subject of further experiment by Buffon, Langollois, Rosenthal, Stokes, W. F. Edwards and others.

Animals that are born with their eyes shut, as dogs and cats, and which have at first very little animal heat, will show signs of life after complete submersion for more than a half-hour in warm media; on the contrary, if a hibernating animal is put in a temperature of about 10 F. below zero, it dies through a paralysis, or inhibition of the center of respiration; but when these same animals are enveloped in an atmosphere or medium of greater temperature than found in either at birth or at apnea, respiration is soon established[2], even to a degree of excessive depth and frequency. And again, Dr. Ackerman has stated that the frequency of respiration is caused by neither want of oxygen nor excess of carbon dioxid in the blood, but alone by the increase of temperature of the whole organism, or heat dyspnea, or what Dr. Isaac Ott calls polypnea.

That there is an anatomic and physiologic area or center in the medulla oblongata which is recognized as presiding over respiration is no longer a subject of doubt or discussion. Experiment has been often enough duplicated to prove that removal of or injury to the medulla oblongata, alone, at once stops all respiratory movements, even though all the muscles of the trunk concerned in respiration—and they are many—and their associated nerves be left entirely uninjured; or, if that smaller tract of the medulla whose limits are not as yet exactly defined, lying below the vasomotor center, between it and the calamus scriptorius, be crushed or removed, respiration ceases though every other part of the body be left intact; so near this is the inhibitory vagus center that it too is generally injured or irritated and the heart's beat arrested or impeded, instant death ensuing.

This very important portion of the nervous system was designated by Flourens, the "vital knot," or ganglion of life; it is now, I believe, generally recognized by physiologists as one of the respiratory centers[3].

The group of dynamics stored in these centers coordinating respiration, is very complex and of wide distribution, as evidenced in impending asphyxia, dyspnea or aroused respiration, when nearly all the muscles of the trunk are called into requisition, reinforced by the rigid extremities fixing the trunk as auxiliaries.

Isaac Ott's polypneic center seems so firmly established that its recognition in this connection confirms the practice to be recommended: he locates this center in the tuber cinereum, and demonstrates that external heat as an irritant to the cutaneous surface carries an excitant to the polypneic center which, acting as a reflex center, sends other impulses that are carried to the adjoining respiratory centers, causing rapid respiration; he asserts that heat is the best external stimulant to rouse the polypneic center—the center of respiration in cases of poisoning or drowning.

Then we have Christiani's expiration and inspiration centers, Martin and Booker's inspiration center in the posterior bodies of the corpora quadrigemina; and Ott's polypneic center; all these subsidiary ones are in the medullary center and through this depot exert their influence on respiratory movements; these subsidiary or subordinate centers are no doubt connected with each other and with the vital center by well-fixed and responsive nerve-paths. It would be a waste of time to rehearse the experiments made in this field of research[4], while the clinical evidence that confirms the existence of such a depot is not rare; and the interrelation of function, physiologic and pathologic, between this and the ganglia of the great sympathetic, or organic brain, adds strength to the position.

"We also know that many cases of head injury by accident, or during delivery at child-birth, appear to end fatally, owing to failure of the respiratory center; in these cases alternate heat and cold to the abdomen and chest tide the patient over this dangerous period and bring about an ultimate recovery."[5] There is no doubt that most of the cases of asphyxia neonatorum are caused by pressure on the occiput during emergence beneath the symphysis and are a traumatism as much as if occurring in an ordinary accident.

Every ultimate structure has its center and its periphery, whatever its shape; the nucleus, nucleoli, surrounding fluid and hyaline wall form an arrangement by which excitation of any part of its peripheral wall finds an active response at its center; the human organism is an aggregation of these mobile, plastic and responsive units of which the new-born is its most delicate expression; the dynamic forces given by the gestative impress are inherent in all the structures; it is our duty to recognize these anatomic structures and physiologic processes in the methods of the resuscitation of the still-born. We know that the syncope occurring in chloroform employed as an anesthetic, induces primary failure of the circulatory mechanism and secondary failure of the respiratory center; the latter fails to act not only because of the damage by the drug, but also because of the anemia of the medulla induced by the fall of arterial tension[6]. We also know how easily syncope can take place where there is general cerebellar anemia, and also where depletion has occurred from traumatism, accidental or surgical, whether attended by shock or not.

---

*Presented to the Section on Physiology and Dietetics, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

Resuscitation in these cases is by prompt depression of the upper zone of the body to favor gravitation of the blood to the dependent cerebellar region and medullary center. Next in importance to this is the supplying of artificial heat externally; and the supplementary pressure of the capillaries by the subcutaneous, subperitoneal or rectal flushings with the "normal salt solution," and a further prone or inverted position to stimulate both the centers of circulation and respiration.

The same fundamental principles adapted to the emergency of resuscitation at the lying-in-bed in the private home or hospital wards will, it is believed, achieve more than the methods usually employed, with less sanguinary and manual exhibition —e. g., such as Schulze's swinging of the child's body through the air, Sylvester's mechanical methods, etc.

If due preparation has been made and anticipated, resuscitation provided for, a basin large enough and an abundance of warm water is at hand, in such a case submersion of the occiput of the collapsed child is easily done and one of the requirements met; but the reverse of what should be is usually done—the hips and legs are immersed, while the head and body are held erect, whereas the feet and body should be elevated and the occiput completely immersed. With a hand resting beneath, this can be done, taking care not to allow water to enter the nasal or oral aperture; then, with the ring and little finger of the left hand, we should elevate the middle body, and with the right hand, or by the aid of an assistant, let fall or dash a half-ounce or so of cold water upon the unsubmerged epigastrium, and soon the reward of a gasp is heard—the stimulus to future respiration. This maneuver can be repeated once in ten or fifteen seconds, an ample time while waiting for return of animation. Should success not come with the first attempt, draw forward the tongue and at the next impact of the cold water a reflex will have gone forward and upward that will surely do its work.

Sometimes in the hurried advance of labor and the emergence of the child, complete equipment is not at hand; then a pint of warm water in which to submerge the occiput is of use, with warm flannels for enveloping the elevated body, and the accoucheur can sit at the bedside treating the child while the placenta and cord are still functionating with the mother. If the cord is short, this still has an advantage over early severance of the funis and removing the child to a remote table for manipulation where observation of the mother is lost and the chances of the child not enhanced.

If, while this manipulation is going on, the placenta is expelled, its maternal surface can be exposed to the air for the blood-absorption of oxygen, according to Dr. S. Stringer's method; here, however, another vigil must be kept, lest passive retrograde circulation ensue and the child become exsanguinated by placental hemorrhage. This may seem an inactive way when compared with the spectacle of swinging a child through the air, or hastily calling for a table and assistants to perform Sylvester's or Hall's resuscitation methods; and it may not seem as simple as the attempts to inflate the lungs, which usually only inflate the stomach; which if there is any good in it is through the reflex at the solar ganglion. Physiologic methods are above mechanical, and recognition of this fact and practice on this line will bring results and recompense.

Clinical Report.

CASE OF ECTOPIC PREGNANCY.

J. HENRY BARBAT, M.D.
SAN FRANCISCO.

The following case illustrates the necessity of giving apparently trivial symptoms due consideration, and acting without delay if we wish to save our patients from unnecessary and serious risk from hemorrhage. Mr. H. came to my office on Friday evening, Nov. 30, 1900, to ask about his wife's condition. He stated that she had pains and some tenderness in the lower abdomen and had been flowing very slightly every few days for ten days previously. Her menstruation had been regular, but at the last epoch, on November 2, she flowed only for one day, her usual time being three or four days. I called to see her the day following and in addition to the symptoms mentioned found that ten days previously she had had a sudden pain in the abdomen, which was followed by considerable tenderness. Examination showed a soft mass in Douglas' cul-de-sac which could not be definitely outlined on account of the tenderness, but which seemed to be more to the left of the uterus. The uterus was about the size of a two months' pregnancy, and felt soft and doughy. After the examination the pain and tenderness seemed to leave, and the patient stated that she felt perfectly well; but the symptoms were sufficiently characteristic to make me feel that an ectopic pregnancy existed, and that the sudden pain which had come on was due to a slight hemorrhage from a rupture of the sac. An immediate operation was advised, and done on the morning of December 30. On opening the abdomen no blood was noticed, but a sponge passed down into the bottom of the pelvis was saturated with dark fluid-blood, showing that hemorrhage had taken place. The left side was examined first and the ovary found enlarged. This was cut into and proved to be a corpus luteum of pregnancy; the tube was normal. The right tube was enlarged at its distal end to about the size of an egg. and had two patches of lymph adherent on opposite sides. The ovary was normal. When the lymph was removed, the points of rupture were disclosed, and bled profusely. The tube was removed close up to the enlargement, leaving fully 2 inches of normal tube; the cut end was split for 1/4 of an inch and the mucosa sutured to the peritoneum. The specimen proved to be a six weeks' pregnancy. The patient made an uninterrupted recovery, as we usually find in all cases which are operated on before severe hemorrhage has taken place.

The case is of interest on account of the meager symptoms and the fact that the ovum which was extruded from the left ovary was fertilized in the right tube. Delay would certainly have resulted in further hemorrhages, with possibly fatal result.

SURGERY OF THE NINETEENTH CENTURY.

About twenty years ago one of the most celebrated surgeons in London made a public address in which he stated that surgery had reached its limits. To-day one of the most famous surgeons of this country announces that the birth of modern surgery dates back barely a quarter of a century.

W. W. Keen, M.D., LL.D., ex-president of the American Medical Association, in his critical survey of the "Progress of Surgery,"[1] traces in broad lines the effect of the two great discoveries in surgery—anesthesia and antisepsis—to their individual results in each branch of surgery; and shows what few surgeons themselves realize how vastly the proportion of human suffering has been lessened, and how greatly human life has been lengthened by the appliances of these discoveries. The desire to bring relief to suffering is too widely human to permit of a narrow national pride, but it can not, nevertheless, fail to be an incentive to American surgeons to remember that some of the most brilliant achievements have come from their fellow countrymen.

After vaccination, which event illumined the history of medicine at the close of the eighteenth century, the most important discovery was that of anesthesia. On Oct. 16, 1846, Dr. John C. Warren first performed a major surgical operation without inflicting the slightest pain. Ether was for the first time administered in the Massachusetts General Hospital, and the very sponge which was then used is still a precious trophy of that hospital. The news of the discovery spread like wild-fire over the whole civilized world, revolutionizing the methods of surgery. Prior to that time an operation was attended with horrors that neither patient nor surgeon to-day can conceive. Only the most heroic would submit, and rapidity was the chiefest recommendation that a surgeon could have. With the freedom from pain has come the modern deliberate, careful, painstaking operations, involving minute dissections and the greatest accuracy where a single stroke of the knife may mean life or death.

It is interesting to recall the rapidity with which the number of patients increased. In the five years preceding the discovery of ether, only 184 persons were willing to be operated on in the Massachusetts General Hospital, so that the students and surgeons were limited to an experience of about three operations each month. In the five years following the introduction of ether there were some eight or nine operations a month; while last year, in the same institution, there were more than 3700 performed.

The discovery of chloroform, by Sir James Y. Simpson, of Edinburgh, in 1847, and the use of local anesthesia during the last few years, has made a surgical operation less painful than a mild attack of illness. Spinal anesthesia, which has been practiced only during the last two years, will probably never take the place of chloroform or ether. Dr. Keen hopes, however, that with the discovery of new chemical compounds the twentieth century will produce the ideal anesthetic, one which will abolish pain and consciousness without danger to life.

Although pain during an operation was completely abolished, yet, as the older surgeons of the country well know, the after-suffering from fever, and the constantly discharging wounds, and the mortality from blood-poisoning, erysipelas, tetanus, and gangrene were as great as ever.

The standard of successful operations has so changed that whereas thirty years ago, before the discovery of antisepsis, when in rare cases a surgeon obtained a primary union without a drop of pus, without fever and with but little suffering, it was considered a marvelous achievement, now it is precisely reversed, and the surgeon who does not get primary union without a drop of pus, with no fever and with little suffering, asks himself: What was the fault with my technique? Dr. Keen says, in a panegyric of praise for the discoverer of antisepsis, that when the International Congress of Berlin, and the British Medical Association in Montreal, welcomed Lord Lister with cheer after cheer, it was but a feeble expression of a gratitude that no words could express.

Lord Lister's discovery was but the beginning of the work which laboratory investigation has furthered. Bacteriologic research has been of as great import to surgery as to medicine; and the discoveries, especially along the line of wound infection, have led to the technique of the modern operation as regards instruments, care of the hands and dressings.

Among the discoveries that American surgeons are proud to attribute to their countrymen, may be mentioned those in surgery of gunshot wounds, the most astonishing record being, perhaps, that of Flührer of New York, who reported a case where the ball entered at the forehead and traversed the entire brain, yet the patient recovered.

Willard Parker of New York was the first to make the profession listen to him when he urged that abscesses appearing above the right groin should be operated on and the patient's life saved. His operation for appendicitis, which has arisen to such prominence, has saved the majority of patients who thirty years ago would have died of localized peritonitis. Until 1885 it would have been thought fatal to operate on perforating ulcer of the stomach. In an inaugural dissertation by Tinker of Philadelphia, 232 cases of such perforating ulcer were reported, of which 123 recovered after operation, whereas formerly the mortality of the disease was 100 per cent. The operation of ovariotomy had its rise in America. Ephraim McDowell, of Kentucky, in 1809, was the first to perform it, and Washington L. Atlee, of Philadelphia, and his brother, were the ones to place it on a firm foundation. Their mortality was about one out of two; but to-day, owing to the improvement introduced by antiseptic methods, the death-rate is seldom over 3 per cent.

---

[1] N. Y. Sun, Feb. 3.

An incidental but very important cause of the advance of surgery has been the increase in journalism and the formation of societies. Every successful operation along new lines is immediately reported, and its technique is spread abroad, calling forth comments and improvements from other surgeons, so that by mutual co-operation the skill of American surgeons has reached a very high rank.

Almost as the last word of the century, on the subject of surgery, was being said, the Roentgen ray appeared, illuminating the hidden parts of the human frame and opening a new and undreamed of method of diagnosis. So in the light of such an unexpected discovery we do not hesitate to hope, with Dr. Keen, that the surgery of the twentieth century may as completely outshine the surgery of to-day as that of to-day outshone that of thirty years ago.

ACUTE POST-OPERATIVE DILATATION OF THE STOMACH PRODUCED BY THE SUPERIOR MESENTERIC ARTERY COMPRESSING THE DUODENUM.

Acute dilatation of the stomach following operations may become the cause of death. Referred by some to central or peripheral nervous disturbances, by others to muscular paralysis and to the influence of the anesthetic, the observations of Kundrat, Schnitzler, Albrecht, and P. Müller show that in many such cases it undoubtedly concerns compression of the duodenum at the duodeno-jejunal junction by the superior mesenteric artery, as described by Rokitansky as long ago as 1845. Albrecht collected 19 cases of this kind from the literature, six of them developing after narcosis. P. Müller[1] refers to five additional cases. He describes two typical new ones with autopsy, and two others in which therapeutic measures appear to have been successful in saving life. The post-operative dilatation may follow operations of any nature, but occurs most frequently after laparotomy. The symptoms may set in immediately after the operation and, unless overcome, they lead to death in from two to five days; very rarely the onset takes place some days after the narcosis. The predominant symptom is profuse vomiting of fluid mixed with bile, but without feculent character. The abdomen is at first usually not distended, and commonly there is no tenderness; thirst is marked. Because the intestinal canal is usually empty there are no passages and no flatus. These and other symptoms are, of course, not diagnostic of any one condition, but add now the presence of a dilated stomach—and dilatation may be readily made out by the usual methods—and certainly the symptom-complex becomes very significant. A brief consideration of the consequences of duodenal occlusion below the biliary papilla will explain the symptoms. The post-mortem findings are said to be typical: great dilatation of the stomach and duodenum, the superior mesenteric artery being tense and compressing the duodenum, but without producing distinct circulatory disturbances; the empty small intestine is always found in the pelvis, the mesentery being stretched. In Müller's cases the gastro-duodenal contents had been forced into the gall-bladder and up into the liver, whose function was thus suspended. Experiments have shown that traction on the mesentery, toward the pelvis, causes occlusion of the duodenum, especially in thin persons. When the small intestines sink down into the pelvis, the mesentery is folded together like a fan, and its length is probably the decisive factor in causing compression, the shorter the mesentery the greater the danger. And as the dilatation of the stomach increases the small intestine is hindered from leaving the pelvis. The complicated anatomical and mechanical factors that enter into this *circulus vitiosus* probably merit further experimental study.

Up to this time the diagnosis of duodenal occlusion under these circumstances has been made three times during life, first by Schnitzler, while Müller now describes two cases. In all three the threatening symptoms were relieved quite promptly and completely by placing the patient in the prone position with elevation of the pelvis with or without emptying and washing out the stomach. Undoubtedly further experience will lead to the establishment of more definite rules for treatment which, naturally, in some cases may have to be operative. The opinion has been ventured that post-operative duodenal compression is not so very rare; spontaneous cure may take place in many cases, in others relief follows lavage of the stomach, in still others the symptoms are attributed to the effects of the anesthetic, and perhaps some are regarded as instances of peritonitis. Suffice it to say that long persistence of post-operative vomiting should direct attention to duodenal occlusion.

THE DEFINITION OF THE "PRACTICE OF MEDICINE."

The essential part of any medical practice act, apart from its enacting clause and the penalties, is the definition of the phrase, "practice of medicine." Ambiguity or incompleteness in this nullifies or renders inefficient the law itself, and some of the measures enacted have suffered from this defect. A bill is now before the New York legislature to amend the medical practice law by adding the definition, which it seems was lacking, and the strictness of the definition attempted will be manifest. The amendment, as reported, reads: "Any person shall be regarded as practicing medicine within the meaning of the act, who shall prescribe, direct, recommend, or advise, for the use of any person, any remedy or agent whatsoever, whether with or without the use of any medicine, drug, instrument or other appliance, for the treatment, relief or cure of any wound, fracture or bodily injury, infirmity, physical or mental, or other defect or disease. This article shall not be construed as prohibiting the service of any person in an emergency, or the domestic administration of family remedies, nor shall it be construed to affect commissioned officers serving in the United States army, navy, or marine-hospital service, while so commissioned, etc."

---

[1] Deutsche Zeitschr. f. Chir., 1900, lvi, 487-511.

If we were to criticise this definition, we should say it was too elaborate and comprehensive on the one hand; even the simplest friendly advice in regard to health could be construed as unlawful under its provisions. On the other hand, any more liberal construction might open the way to a laxity that would seriously impair the usefulness of the law. It is not generally advisable to enact laws that it is understood are in the whole or in part likely to pass into innocuous desuetude, to use an often quoted term. The definition of the Georgia medical practice act meets this difficulty in one way and appears in most respects quite satisfactory. It says, *Sec. 1478:* "Practice Medicine Defined.—For the purpose of this chapter, the words 'practice medicine' shall mean to suggest, recommend, prescribe or direct, for the use of any person, any drug, medicine, appliance, apparatus, or other agency, whether material or not material, for the cure, relief, or palliation of any ailment or disease, of the mind or body, or for the cure or relief of any wound, fracture or other bodily injury or any deformity, after having received or with the intent of receiving therefrom, whether directly or indirectly, any bonus, gift or compensation." This seems to cover very nearly every demand and, by inserting the element of compensation in the definition, is free from the objection above noted. Whether or not it leaves a chance for some lawyer to make a hole in the law, it might be presumption to say, but it hardly appears so to a non-legal mind. After all, it is an open question whether the simpler definition of the Nebraska law is not better than these more elaborate attempts and just as effective: "Any person shall be regarded as practicing medicine within the meaning of this act who shall operate or profess to heal or prescribe or otherwise treat any physical or mental ailment of another." The supreme court of that state has twice passed upon this law, once when it decided that the practice of a "Christian scientist" came within the definition, and recently,[1] when it decided that the practice of so-called osteopathy also was within the meaning of the act. The courts could hardly construe this as covering any simple friendly counsel as quickly as they might the more particularized definition of the New York law, while it is nevertheless complete enough to cover all bona-fide attempts at practicing medicine. It would, moreover, it seems to us, be less likely to stir up opposition and attempts to destroy the law through the courts, than would the more particularized definition proposed in New York. A law that too openly tempts an interpretation that it forbids the application of a porous plaster or the fitting of a crutch seems like a *reductio ad absurdum* to the average layman, and may easily be so taken by a judge or jury. The wisdom of the serpent and the harmlessness of the dove are especially needed in framing laws that strike so many interests as do those directed against quackery.

THE INFLUENCE OF SYPHILIS UPON THE MORTALITY OF THE LIFE-INSURED.

The opinion that syphilis plays an important part in the production of chronic diseases of internal organs, largely abandoned through the influence of Hunter, came to the fore once more through the work of Virchow in 1858, "On the Nature of Constitutional Syphilitic Affections." Since then the importance of syphilis has become recognized more and more. Specific diseases of the bones, the nervous system, the liver, and other organs, have been studied carefully. Heubner's work in 1874, "On the Luetic Diseases of the Cerebral Arteries," has been of signal value, because it laid the foundation for the study of syphilitic disease of the vessels in general and the various serious pathological conditions resulting therefrom in the brain, the heart, and the large vessels. We know now only too well that syphilitic meningitis and cerebral gummas, softening of the brain, and coronary disease may develop years after the infection. General paresis, arteriosclerosis and aneurysm are also regarded as having often a syphilitic basis, general paresis in the opinion of many being always a luetic result. In few diseases has the *practical* value of pathological anatomy received better illustration than in the case of syphilis. Deprived of the aid obtainable from the demonstration in a suspected lesion of the specific etiologic agent, investigators have been forced to rely upon the character of the anatomical changes in order to differentiate syphilitic from other and often strikingly similar lesions. And it is not impossible that on account of the natural limitations of this method the knowledge of luetic manifestations may have suffered. Nevertheless, a mass of information has accumulated and by following certain broad lines of inquiry it is generally possible to reach fairly definite conclusions in regard to some of the questions here broached.

Thus Runeberg,[1] of Helsingfors, studied the influence of syphilis upon the death-rate of the insured in a company whose applications, death-certificates, etc., he could use for this purpose; information was secured also from the physicians and the relatives, especially in cases of death from general paralysis. Between 1875 and 1897 there were 734 deaths, 11.4 per cent. of which

---

[1] JOURNAL A. M. A., xxxv, p. 1578.

[1] Deutsches Med. Woch., 1900, 18-20.

—or 84—are referred to syphilis, 21.3 per cent. to tuberculosis, and 10 per cent. to pneumonia. There were 22 general paralytics among the 84 cases referred to syphilis, and in 16 of these a definite history of syphilitic infection was obtained; 31 of the 84 succumbed to heart disease; 21 to brain and cord diseases; and 3 to chronic nephritis, etc. In most of these cases syphilitic infection could be traced directly. In 69 cases the period between infection and death averaged 20.2 years, the average age of the whole 84 being 43.4 years, and the average time between the issuance of the policy and death 8.1 years. The same company, during the period of 1874 till 1895, accepted 11,359 applicants; of these 619 acknowledged syphilis, and the deaths of this group were 78, or 12.6 per cent., while of the remainder, 656, or 6.1 per cent., died. Runeberg is of the opinion that at least 25 per cent. of deaths from heart disease, hemorrhage into the brain, and cerebral softening in persons under 50 without distinct specific history should be placed at the door of syphilis. These figures, although small, throw a strong light upon syphilis as an etiologic factor in fatal diseases of the vital organs. There is no question in regard to accuracy and careful handling of the figures. The articles also contain much of interest to the experts in insurance.

INFLUENCE OF INANITION ON THE INFECTION WITH *THE COLON BACILLUS.*

The many and various factors that favor or oppose infections are imperfectly understood. The complexity of many processes that enter into the consideration of such questions makes it difficult to give any radical explanation of the various phenomena, clinical and experimental, observed in this interesting field. Roger and Josue[1] starved rabbits for five to seven days and then allowed them to feed for seven to eleven days, when they were infected with the colon bacillus. The animals that had fasted withstood infection much better than the controls. Here it appears that the resistance to infection is rapidly increased after fasting, increased above that of the average normal animal. Conditions similar to this may explain the apparently contradictory results often seen in the study of the reaction of animals to infections. The authors also suggest that religious fasts, undertaken as spiritual discipline, for similar reasons may be of hygienic importance considering the circumstances under which voluntary abstinence from food is often practised.

THE APPENDIX VERMIFORMIS.

The generally accepted teaching and popular belief that the appendix is simply an evolutionary remnant appears to be contradicted to some extent by some recent researches. At the meeting of the British Royal Society, December 3, last, Dr. R. J. A. Berry reported that, from a microscopic study of certain vertebrates—rabbit, cat, pigeon—he found a marked accumulation of lymphoid tissue at the cecal apex, reaching its maximum development about one week after birth. In a general way he found the presence of this sort of tissue the characteristic feature of this region, and in the vertebrate kingdom generally, he stated that such an accumulation of lymphoid tissue represented the appendix. As the scale is ascended toward the higher vertebrates, this becomes differentiated into a special organ, the appendix, which is therefore not a mere vestigial structure, but a specialized part of the alimentary canal. If this be the case, however, it does not necessarily follow, from what he tells us, that the appendix in man is not a vestigial remnant, though his reported findings cast a little cloud in its title as such. It is just possible that even in man it may yet have a slight useful function, but one that is badly overweighted by the occasional disadvantages from its presence in the organism.

HAVANA'S HEALTH FOR 1900.

The report of the chief sanitary officer of Havana, Cuba, Mayor W. C. Gorgas, for the year 1900, contains some interesting data, and shows a very creditable state of affairs from a health point of view. The annual death-rate is the least that has been reported for the decade, the lowest previous one, that for 1893, having been 38.68 per thousand, while for 1900 it was only 24.4, which is not a high figure for a tropical city. The existence of yellow fever to some extent was to be expected, and during the past year it found specially favorable conditions for its spread among the 24,000 immigrants, most of whom were non-immune. Still, it was kept well in hand; of the 920 Spaniards stricken, the percentage of deaths from the disease was only 26.3, while among the 235 Americans it was only a little more than one-half as great. The epidemic, if it can be called by that name in a city that is rarely free from the disease, was not a formidable one, and evidently had but a slight influence on the general mortality ratio. Tuberculosis in Havana was nearly four times as fatal as yellow fever, and caused over one-seventh of the total mortality, thus showing that it is as little controllable there as in more temperate climates. Another disease, fortunately rare elsewhere—tetanus—caused more than half as many deaths as yellow fever, and is responsible for over 3 per cent. of the total mortality. The report is a most creditable showing of the sanitary management of very difficult problems under the military control of the United States.

THE PRESS AND QUACKERY.

The public press can do much to show, in their true colors, the characters of the various charlatans who prey upon the public. Often, however, the press is subsidized in an advertising way, though occasionally we find a publication rising above this. During the past few weeks a "divine healer" has located in Cincinnati, Ohio, with a corps of assistants, the latter of whom seem to have been injected with the "divine fluid" by the head "healer," for when trade was brisk or the exigencies of weather such that the "doctor" demurred about going out, one of the assistants was sent to answer calls, and it is said at the rate of $5 a visit. The *Cincinnati Post,* in order to investigate the claims of the "healers," sent a reporter with instructions to feign some illness in order to gain admittance, but as every one who applies is "treated" for a "trifling consideration," this proved to be a matter of very little difficulty. The experiences of the reporter have been published in detail, and among other things, indicate that the chief assistant has followed, at one time or another, almost every known profession, his immediately previous efforts having been directed to the stage, in the way of illustrated songs. After exposing a number of so-called cures, the reporter states that, on leaving the institution, she was asked for a testimonial, which the *Post* published, as follows: "To Dr. . . . . Having entered the . . . . . Institute in perfect physical condition, without an ache or pain, the managers of the institution were kind enough to supply me with a varied and choice assortment of ailments for which I paid the very reasonable sum of $21. I can recommend your heelers to all seeking a fine collection of diseases at a nominal price. Yours for health, J. M. P." The entire matter was treated in a half serious, half cynical style that will undoubtedly appeal more to the public at large than a library of abuse, and it is to be hoped that other newspapers will be stimulated to efforts along the same line. At any rate the profession of medicine owes hearty thanks to the *Post* for its aid, and the laudable attempt to purge the city of the human sharks who have been so long allowed to gorge themselves upon their innocent and gullible victims.

PROPER AND IMPROPER METHODS OF CLEANING PUBLIC BUILDINGS AND CONVEYANCES.

Often the more or less elaborate process of cleaning of rooms and conveyances becomes a means of dissemination of bacteria-laden dust rather than of removal of dust and dirt. In many cases one may very readily convince himself that the cleaning merely disturbs the accumulated dust, which soon settles down again upon the very articles and floor just dusted. This improper method of cleaning is seen only too often in public buildings and public conveyances as well as in private houses. The question has been subjected to a scientific inquiry by Elmer W. Firth, sanitary engineer, who conducted a series of experiments upon micro-organisms in the air of public buildings and conveyances as the result of improper methods of cleaning.[1] He points out that correct cleaning is based on certain principles, among which may be mentioned the following: Absorbent floor materials should not be allowed to conceal dust and dirt; non-absorbent flooring should be used in public places; this means the removal of carpets from churches and theaters and of fiber mats from cars and boats; linoleum and rubber mats may be substituted. Damp sawdust on floors is useful for retaining some of the dust raised in sweeping. Dust and organisms suspended in the air after sweeping settle more quickly in a closed room than in a ventilated one. Strong currents may keep organisms in suspension for a long time unless the draught passes directly through the room. For these reasons sweeping and dusting in public places should be done at such times as to allow settlement of the dust before occupancy. Dry sweeping and dusting are condemnable and should never be allowed in the presence of numbers of people. Absolute removal of the solid impurities of the air that settle in all buildings, and of the dust after sweeping, is best accomplished by the use of damp cloths, and frequent mopping and washing are necessary. As dampness is to be avoided, wooden flooring should be substituted with stone or tile. The material accumulated in cleaning should be destroyed or disposed of in such a way that "it will not be merely a nuisance transferred to another place," which is the great objection to many methods of cleaning.

THE DUTY OF THE PHYSICIAN TO THE STATE.

While the political atmosphere in some of our large American cities and states is not of the most respirable character, there are indications that the majesty of the law is not held at too low an estimate. Every now and then evidence is afforded that the courts are not inclined to look upon the acts of the medical man with the liberality and consideration to which his profession would seem to entitle him. Only recently a judge in an eastern city, in remitting the fine imposed upon a physician for contempt of court, because he was late in answering a subpena, by reason of attendance on a patient seriously ill with diphtheria, is quoted as saying that "it were better that the patient should die than that the Commonwealth's witnesses should place themselves in contempt of court." We are sure this new judgment will not receive universal acceptance, either by the bench, the bar, the medical profession or the laity. The physician's occupation is not a business in the ordinary sense of the word, and it would bode ill for the entire fabric of society if, in any case of gravity, particularly in the existence of an emergency, he were compelled to yield the welfare of his patient to his obligations to the state. The state is at best but the aggregation of its citizens, and it has no right, by arbitrary methods, to jeopardize the life of a single one of its constituents. On the contrary, there is an indissoluble bond between the two, each of which must recognize the prerogatives and the privileges, not less than the duties and the obligations of the other. We think it will by common consent be agreed that the first obligation of the physician is to save life and relieve suffering. Only after he has fulfilled this requisition can he devote himself to his duties to the state. That this is sound doctrine, not alone in theory, but likewise in practice, the experience of the centuries amply demonstrates. But it is by no means implied that the physician is justified in any degree in neglecting or shirking his obligations to the state. On the contrary, these are not less incumbent on him than on other citizens; but when it comes to the question of whether he shall jeopardize the welfare of his patient to obey the summons of the court, we are sure that there will ever be but one decision.

TEACHING AND DIAGNOSIS OF TYPHOID FEVER.

In his recent paper before the Philadelphia County Medical Society, "On Perforation and Perforative Peritonitis in Typhoid Fever,"[1] Osler makes a few remarks concerning certain aspects of the treatment of typhoid fever that should receive the respectful attention of the medical profession. In order that the death-rate from typhoid fever may reach the lowest possible point a practical, first-hand knowledge of the disease in all its manifestations is requisite. The senior students should, he urges, see typhoid patients day by day and watch their progress from week to week. That this is not done very generally is known only too well. That there are cases enough in the large cities to provide instruction of this sort is not to be doubted; but such instruction is not given because the courses are not so arranged and because the medical schools have not proper control of the hospital facilities. Brilliant lectures on typhoid fever are given, recitations are held, books are read, and cases are shown in the amphitheater, but typhoid fever is not learned satisfactorily in that way. And this is shown by the experience in the last war. "The worst indictment," says Osler, "ever brought against the medical schools of this country is contained in the report by Reed, Vaughan, and Shakespeare on the prevalence of typhoid fever during the Spanish-American war. Shades of W. W. Gerhard and of Austin Flint! The young doctors, to whom were entrusted scores of valuable lives, had practically not gotten beyond the nosology of Rush. Of the total number of 20,000 cases of typhoid fever, only about 50 per cent. were diagnosed by the regimental or hospital surgeons." In 80 of 85 cases sent to civil hospitals in Baltimore the diagnosis was changed from malaria to typhoid. Similar instances occurred elsewhere. The authors of the report mentioned venture the statement that the army surgeons probably did better than the average physician in his private practice. Whatever the truth may be, this is but a lame and impotent apology that emphasizes still more the need for different and better methods of teaching. Men like Osler render the profession great service by courageously speaking their minds on topics of such basal import as this.

Medical News.

ALABAMA.

Smallpox is spreading in and around Huntsville. Cases have been reported in the city, West Huntsville, Dallas, Meridianville and Madison.

Dr. Thomas W. Ayers, Anniston, has given up his practice and will start with his family for China, sailing from San Francisco, March 15. He goes out as a medical missionary under the auspices of the Southern Baptist Board, and will be stationed at Hwang Hi-en, North China.

Hillman Hospital, Birmingham, has appointed the follow medical staff: Medical—Drs. Cunningham Wilson, Thomas D. Parke, Baxter Rittenberry, John W. Barclay, Charles Brenand, and Robert V. Mobley; surgical—Drs. Benjamin G. Copeland, William P. McAdory, Charles Davis, William H. Wilder, Edward P. Riggs, and Lewis C. Morris.

Opposition to discrimination in favor of Mobile Medical College is the cry of the State Medical Association and of the Jefferson County Medical Society. They consider that to allow the graduates of the Mobile Medical College to practice medicine in Alabama without undergoing the usual examinations before the state or county boards would be unfair to the Birmingham Medical College and the graduates of the leading medical colleges of the North and East, and would lower the standard of the profession in the state.

CALIFORNIA.

Visalia has appointed a new board of health, of which Dr. F. A. Combs is president.

San Francisco's mortality in December was the largest in its history—680 deaths. A large percentage were from la grippe, or pneumonia, exhaustion, etc., following that disease.

Visalia Sanatorium, which was not yet completed, but was to have been opened February 15 by Drs. Thomas O. McSwain and William W. Cross, Jr., was destroyed by fire January 25.

Diphtheria has broken out in the City and County Hospital, San Francisco. Two nurses, one physician and one inmate have the disease, and a number of patients with sore throats are isolated and under suspicion.

Clara Barton Hospital, San Francisco, has been incorporated by Drs. J. Henry Barbat, George H. Evans, Edward G. Frisbie, Charles A. Dozier, Elmer E. Kelly, Henry B. A. Kugeler, and Frank B. Carpenter. A lot for the new institution has been selected and a building to cost not less than $50,000 will be erected.

DISTRICT OF COLUMBIA.

The remains of Major John G. Davis, surgeon, U. S. V., who died in Manila, November 1, were buried with military honors in the National Cemetery, Arlington, January 16.

Dr. Alonzo B. Richardson, Washington, superintendent of the Government Hospital for the Insane, has been elected to the chair of mental diseases in the medical department of the Columbian University.

The Episcopal Eye, Ear and Throat Hospital, Washington, recently elected Dr. E. Oliver Belt secretary of its board of governors, re-elected the assistant and attending physicians, and also elected Dr. John B. Nichols pathologist.

Health office changes at Washington include the withdrawal of Dr. Lewis J. Battle, inspector of smallpox service; the transfer of Dr. Creed W. Childs to the smallpox inspection and the assignment of Dr. Uriah J. Daniels to duty as physician to the poor.

The Indigent Insane.—Providing a bill submitted to Congress be passed, this class will hereafter be admitted to the Government Hospital for the Insane, on petition of the Commissioners of the District filed in its supreme court, which court shall issue a writ *de lunatico inquirendo*, whereupon the marshall shall impanel a jury from the jurors in attendance on the criminal courts, who shall perform this duty in addition to their duties in the criminal court.

ILLINOIS.

Dr. Edward Bowe, Jacksonville, was appointed county physician of Morgan County, January 25.

Dr. James Selkirk has been elected to the Aurora Hospital board, in place of Miss Nellie Higgins.

Dr. Elnathan P. Hathaway, Ottawa, has been appointed a member of the board of pension examiners, to succeed Dr. J. J. Taylor.

Bills have been introduced in the legislature appropriating $383,100 for the Illinois Northern Hospital for the Insane at Elgin, and $490,600 for the Illinois Southern Hospital for the Insane at Anna.

Silver Cross Hospital, Joliet, is raising the $4000 required to make John Lambert's offer of $500 operative. This is expected to be sufficient to pay all indebtedness and place the institution on an independent basis.

Chicago.

Dr. Christian Fenger has gone to the Gulf Coast for a month.

Dr. Nicholas Senn has returned from his vacation trip to Central America.

Lull in Smallpox.—The grave apprehensions caused by the discovery of thirteen cases of smallpox in one day have not been realized, and the situation at present is reassuring, no new case having been detected during the first four days of this week. The record of no case among the recently vaccinated is still unbroken, and this lesson, upon which too much stress can not be laid, is causing a resort to vaccination on a scale that is the best assurance against any serious epidemic spread of the disease.

Public Health Conditions.—As indicated by the bills of mortality the public health conditions maintain the improvement noted in the bulletin of the health department of two weeks ago. There were 32 fewer deaths reported for the week ended February 2 than for the week before, and 54 less than for the corresponding week of 1900. The death-rate among the aged, however, still continues high—23 per cent. of the total, as against a normal 20 per cent. of those over 60 years of age, and this notwithstanding a reduction in such diseases as apoplexy, Bright's disease, consumption and nervous diseases. Deaths from uncomplicated influenza have remained nearly stationary in number for a month, and the epidemic has probably reached its height, although its complications will continue to be manifest in the new crop of pneumonia and bronchitis which will follow the snow storm of February 2 and 3.

Attending Staff of Cook County Hospital.—The organization of the attending staff of the hospital for the ensuing term of two years, occurred January 31. Dr. Denslow Lewis was re-elected president and Dr. L. Blake Baldwin secretary. The executive committee consists of: Dr. Arthur R. Edwards, chairman; Dr. Charles F. Swan, secretary, and Drs. William E. Quine, James B. Herrick, John P. Webster, Orville W. MacKellar, Mary Jeannette Kearsley and the president and secretary ex-officio. The staff is constituted as follows: Surgeons, Drs. Denslow Lewis, Charles F. Swan, Leonard St. John, Weller Van Hook, C. Pruyn Stringfield, William E. Schroeder, Wladyslaw A. Kuflewski, John B. Murphy, Thomas A. Davis, John Leeming, Frederick S. Hartman, Edward L. Moorhead, Albert I. Bouffleur, Charles Davison, Samuel L. Weber, John W. Tope of Oak Park, Daniel H. Williams, Aime P. Heineck, Francis W. McNamara, Orville W. MacKellar, Daniel N. Eisendrath, Frank R. Byrnes, Gerhardt S. Seim of Blue Island, John P. Webster, A. E. Halstead, Herbert R. Hammond, Robert A. Letourneau, Thomas J. Conley, Edward H. Lee, and Mary Jeannette Kearsley; physicians, Drs. Frank Billings, Arthur R. Edwards, James B. Herrick, Charles C. O'Byrne, E. Fletcher Ingals, William E. Quine, B. McPherson Linnell, John A. Robison, Florence W. Hunt, Thomas A. Noble, J. H. Dolamore, Robert H. Babcock, Robert B. Preble and Arthur E. Price; pathologists, Drs. Ludvig Hektoen and William A. Evans; dermatologists, Drs. L. Blake Baldwin and Maurice B. Sincere; obstetricians, Drs. Effie L. Lobdell and Frank B. Earle; diseases of children, Drs. Frank S. Churchill, Josephine A. Jackson, William J. Butler and Isaac A. Abt; ophthalmologists, Drs. Allen T. Haight and J. G. Huizinga, and nervous diseases, Drs. Sanger Brown and Daniel R. Brower.

KENTUCKY.

Paduca's Board of Health met for reorganization January 17 and elected Dr. W. T. Graves, president.

Dr. Edward N. Simpson, Milldale, has been appointed physician of Kenton County, in place of Dr. William F. Cook, deceased.

The decision of Judge Toney, against "Dr." Harry Nelson, in a suit to compel the State Board of Health to license him to practice osteopathy, has been reversed by the Court of Appeals.

Reporting Smallpox.—The Board of Health of Lexington has adopted resolutions to the effect that, in the future, regular weekly statements of the presence of smallpox shall be published over the signature of the president of the board, and that a warrant shall be issued against any physician failing to report a suspicious case.

LOUISIANA.

Dr. Oscar Czarnowski, New Orleans, was robbed of jewelry, valued at $1000, by burglars, January 22.

Dr. William P. Brewer, New Orleans, has been elected president of the Association of the Army of Northern Virginia, and Dr. Felix Formento, also of New Orleans, secretary.

The suit involving the position of health officer of New Iberia has been decided in favor of Dr. William J. Emmer, who will continue as health officer pending appeal and injunction.

The Alumni Association of Tulane University, New Orleans, January 19, elected Drs. Frederick W. Parham and O. L. Porthier to represent the medical department on the executive committee during the ensuing year.

MASSACHUSETTS.

Two Everett physicians were fined $50 each, January 24, for neglecting to report a case of contagious disease to the local board of health.

The new schedule agreed to by the physicians of Gardner became effective Feburary 1, but before that time one of the signers of the agreement withdrew his name, as he said, in justice to a number of his patients and as a matter of business.

The mortality of Worcester for 1900 was 2159, equivalent to an annual death-rate of 18.77 per 1000. The births registered numbered 2223. Lung and throat diseases caused 694 deaths, or 31.21 per cent of the total mortality, while tuberculosis is reported to be the cause of 281 deaths.

MICHIGAN.

The medical staff of St. Joseph's sanatorium, Mt. Clemens, has been organized with Dr. Joseph M. Croman as secretary.

A bill has been introduced in the house of representatives providing for an appropriation of $200,000 for a state sanatorium for the care and treatment of nervous diseases.

Attorney General's Decision.—The attorney-general, to whom was submitted a resolution adopted by the State Board of Health relative to the legality of the action of the Board in appointing its members as State Communicable Disease Inspectors under act No. 47 of the laws of 1893, and to the question of compensation for services thus rendered and expenses thus incurred, has decided that the State Board of Health has no authority to appoint its members as inspectors and the members of said board are not entitled to compensation for services as members of the Board or as inspectors.

MINNESOTA.

Of twenty-five candidates who took the recent examination for license to practice in the state, 17 passed and are duly licensed.

A St. Paul physician has had his license taken away by the State Board of Medical Examiners, for violating the Code of Ethics by advertising.

Dr. William S. Fullerton, Winnebago City, has been appointed to fill the unexpired term of Dr. William Corpron, Minnesota Lake, resigned.

Registration of Osteopaths.—A bill has been introduced by Senator Horton, creating a state board of examiners and registration for osteopaths. The bill provides for twenty months of study and the passing of a satisfactory examination, and provides further that the members of this sect shall not prescribe any drugs.

MISSOURI.

In Kansas City, a party who resisted vaccination was fined $10 on January 21.

A St. Louis physician was fined $50, January 25, for failing to report a case of smallpox.

Dr. Zachary T. Martin, Lathrop, has been appointed physician to the penitentiary at Jefferson City.

To Check Smallpox.—The bill passed by the legislature, January 22, relative to the checking of smallpox in the state, provides for a county board of health in each county to be composed of the judges of the county court of each county and a reputable physician to be appointed by them. These county boards of health are to have the same powers within their counties as are given to the State Board of Health within the state respecting quarantine regulations and the prevention of the spread of malignant, contagious and infectious diseases. The board is given power to pay, out of the county treasury, reasonable expenses incurred by it, but it is to have no power to raise a quarantine established by the State Board of Health.

NEW YORK.

Dobbs Ferry is to have a hospital, and steps are being taken to begin the erection at once.

A new quarantine hospital for Buffalo is now a certainty. Its location will probably be outside the city limits on the county farm site.

Dr. Francis M. Deems, now of Flushing, but at one time a well-known physician of Manhattan, sustained a fracture of his hip while getting off a cable car on January 30.

New York's Health.—According to the bulletin of the State Board of Health, there were 128,468 deaths in the state during 1900, which exceeds the previous year by 6647, and the average for the past five years by 8000. It is thought that the influenza epidemic probably added 11,500 to the mortality.

New Garbage Crematory.—The State Board of Health has approved the plans for the reconstruction of their plant in Checktowoga, outside the city limits. The new plant will resemble the old one, destroyed by fire, with the exception of some new modern appliances to facilitate the work of garbage destruction.

Research Work.—A number of prominent medical societies have adopted resolutions urging Governor Odell not to interfere with the important research work that is being carried on at the Pathological Institute of the New York state hospitals, but instead to give it generous support and foster the work already begun.

Overcrowding of Insane.—There is a great overcrowding in all departments of the Manhattan State Hospital for the Insane, there being 6000 patients where not over 5000 can be properly accommodated. The superintendent has called attention to the insufficient accommodation, in his annual reports for the past two years, but relief has not yet come.

Fitch Hospital to Close.—It has been decided, by the hospital committee of the Charity Organization Society, Buffalo, to close the Fitch Accident Hospital, March 1. The hospital has been poorly endowed and the organization believes that there being another emergency hospital in the city, and because of the great cost of conducting it, the funds could be better expended in charity organization work proper for relief and investigation of poor cases.

New York City.

Mothers' and Babies' Hospital.—The directors of this maternity hospital, which has been in existence for over eighteen years, have decided to close the institution after May 1, unless the necessary financial support is forthcoming before that time. The hospital accommodates about 40 in-patients and attends to about 130 cases in the tenements each month.

Mt. Sinai Hospital.—Contributions to the building fund of this institution are coming so satisfactorily that work is to begin on the new buildings at once. There will be, in all, nine buildings, occupying the entire block bounded by One Hundredth and One Hundred and First streets and Fifth and Madison avenues. The total cost is to be $1.600,000, of which all but $225,000 has been contributed. There will be accommodations for 360 medical and surgical cases.

Practice of Midwifery.—Assemblyman McKeown, of Kings county, has introduced into the legislature a bill to regulate the practice of midwifery in New York City. It authorizes the Board of Health to appoint, on or before July 1, a board of examiners in midwifery, consisting of the sanitary superintendent of the board of health, the assistant sanitary superintendents of each borough, and the chief inspector of contagious diseases in the Borough of Manhattan. They are to meet at prescribed intervals, examine candidates and issue certificates to the successful ones, for a fee of $10. They shall have power, after a proper hearing, to recommend to the board of health the revocation of a license. All licensed midwives must register annually at the office of the board of health, before July 1. A fine is to be imposed on all persons practicing midwifery without a license.

Smallpox Among New York Italians.—Smallpox has broken out afresh in this city, in the upper section known as "Little Italy," where the people have made every effort to conceal its existence from the authorities. Of the 38 cases from this region during the past week, not one of the afflicted had been vaccinated. A midnight raid was made by 125 physicians of the board of health and an equal number of policemen, and in this way several cases were discovered and almost every person living in the district was vaccinated. They also found a child who had died of the disease. The fact that smallpox has broken out among these people means that in all probability new cases will soon appear in widely separated parts of the city, because the Italians have been working in all parts, and have had an excellent opportunity to spread the disease.

Grand Jury Findings Against Bellevue.—The grand jury for January has handed down a strong presentment against Bellevue Hospital. After careful comparison of the records of Bellevue and of the Manhattan State Hospital for the Insane, including a valuable collection of photographs belonging to the latter institution, it was found that out of 700 patients sent from Bellevue Hospital to the State Hospital bruises and other marks of bodily injury were found to be present on 250 patients, and the testimony offered convinced the jury that these injuries had not been received while in transit between the two hospitals. The presentment further says: "It is fairly deducible from the testimony submitted to us that in point of fact the medical board is directly and absolutely responsible for the administration of Bellevue. It has not been made clear to us how this state of affairs has been brought about, but it would appear that it has resulted from the gradual and steady encroachment of that body upon the prerogatives of the commissioner of charities and the superintendent of the institution." Regarding the practice of some hospitals of transferring their dying patients to Bellevue Hospital, Superintendent Stewart makes the startling statement: "117 cases of this kind have been reported as occurring within one year." Judge Truax has refused to grant a change of venue in the case of the three former nurses of Bellevue now under indictment for having caused the death of Louis Hilliard in the insane pavilion.

NORTH CAROLINA.

New Hospital and Training School.—The H. J. Reynolds hospital and training school for nurses at Winston-Salem, has raised more than $4000 for the $5000 required to secure the $5000 offered by Mr. Reynolds, and it is expected that the building will be erected immediately. There is urgent need of such an institution for colored persons in the locality, and both white and colored appear equally interested in the project.

OHIO.

Dr. Lewis A. Molony, late surgeon, U. S. A., has returned to Cincinnati.

Another arrest at the instance of the Ohio State Board of Medical Registration has been made in Cincinnati, for the practice of medicine without having been registered in the state.

OREGON.

Osteopaths, according to press reports, are not to be granted certificates to practice in Oregon, by the State Board of Medical Examiners.

Bills creating a state board of health and changing the present system of conveyance of the insane to asylums are to be introduced to the coming session of the legislature.

PENNSYLVANIA.

Higher Medical Education.—The State Medical Council, at its winter meeting, adopted a standard of such a degree that it would comply with the high requirements now in vogue at the University of Pennsylvania and other of the foremost medical colleges. The curriculum provides for "four years of exclusive medical study." The Council is making an effort to influence legislation at Washington, toward passing a law which shall be of national scope.

Philadelphia.

Bequests of $10,000 have been left to both the St. Joseph's and St. Mary's hospitals.

Dr. George W. Pfromm has been appointed chairman of the Physicians' Board of Civil Service Examiners, to succeed Dr. J. H. Anders, resigned.

Dr. Simon Flexner has been appointed pathologist of the Pennsylvania Hospital, and director of the Ayer Clinical Laboratory, to succeed Dr. H. W. Cattell, resigned.

SOUTH DAKOTA.

Vaccination Law Valid.—According to press dispatches the recent decision of the supreme court in the case brought by the Board of Education of Lead, against George W. Glover, involving the power of the board to exclude a pupil from school for refusing to be vaccinated, is that the boards of education and health departments have power to order vaccination and to exclude from school those who refuse to comply with the order.

WISCONSIN.

The State Board of Medical Examiners, at its meeting in Milwaukee, in January, passed favorably on 74 applications for license to practice, about twenty applications being held over.

An osteopath, of Waukesha, who was convicted, January 3, of illegal practice of medicine, has been fined $25 and costs. He expects to appeal and to demonstrate in a higher court the unconstitutionality of the state law.

Marinette's physicians are said to have banded themselves together and passed resolutions asking the city council to raise the annual salary of the health officer from $200 to $1000, and that he be nominated by the physicians. They have also pledged themselves individually not to accept the office unless these terms are accepted.

CANADA.

Montreal's deaths numbered 150 last week. Scarlet fever claimed 20 victims and la grippe 6.

Diphtheria, during the month of January, numbered 169 cases in Toronto, with 20 deaths.

Dr. J. G. McDougall, Amherst, N. S., has been appointed provincial examiner in anatomy in connection with the Medical College of Halifax, N. S.

Ottawa's Board of Health have recommended to the Council that the resignation of all its sanitary officers, including that of the health officer be requested.

Montreal's civic hospital is very much overcrowded, and in order to assist the physicians in charge Dr. Charlton, of the Royal Victoria, and Morin, of the Laval University, have volunteered their services.

Tribute from McGill.—On the morning of February 1, the medical students of McGill, to the number of 500, and the entire medical faculty, marched to the Queen's statue to do honor to the memory of their beloved sovereign. Four students headed the procession, bearing on their shoulders a large cushion of natural carnations. Amid a profound silence, as the faculty and students gathered around the statue, the four students advanced and laid the cushion at the foot of the statue. The cushion was in the form of the star of the Order of the Garter; and the design, including the motto—*Honi soit qui mal y pense*—had been worked out in carnations, violets and daffodils. Attached to it with McGill ribbons was a card bearing the words: "A token of life-long veneration and esteem from her loving and faithful subjects, the McGill medical students."

Royal Victoria Hospital, Montreal.—The annual meeting of this institution was held last week, and a resolution passed referring to the death of Her Majesty, Queen Victoria. The following new appointments to the medical staff were made: Clinical assistant in medicine, Dr. W. S. Morrow; in neurology, Dr. A. Shirres; in surgery, Dr. E. W. Archibald; in ophthalmology, Dr. F. W. Harvey; in laryngology, Dr. W. H. Jamieson; assistant in pathology, Dr. A. G. Nichols; in bacteriology, Dr. H. B. Yates; director of clinical laboratory, Dr. A. A. Bruere. The superintendent's report showed that 2619 patients had been admitted to the hospital during the year. Of these, 1604 were Protestants, 964 Roman Catholics, 34 Jews and 17 of other faiths; 1469 were free, 741 public ward patients, paying 50 cents a day, and 409 private patients; 2006 were residents of Montreal, and 613 were sent from the country districts. There were 82 more entered than for the previous year. On Jan. 1, 1900, there were 157 remaining in the hospital; and during the year 2582 have been discharged, of whom 1420 were cured, 698 improved and 172 unimproved, 164 not treated, 128 died, and 194 remained in on Dec. 31, 1900. Of the 128, 29 died within forty-eight hours of their admission. The death-rate for the year was 4.95 per cent., or, if those dying within forty-eight hours after admission were deducted, the death-rate would have been 3.83. The total cost per day per patient has been $1.47 as against $1.55 last year; the cost per day of maintaining each person in the hospital, staff, servants and patients, being 82 cents. The income for the year was $129,570.34, and the ordinary expenditure amounted to $99,208.62, the balance of $30,361.72 being applied toward the cost of the new out-patient department, and the power-house and laundry building. It was announced that plans have been prepared for a pavilion for the isolation of infectious diseases, and it is proposed to proceed at once with its erection.

FOREIGN.

In Vienna the appointment of medical inspectors for schools is being considered.

Dr. Hahn has been sent by the Munich university to study the plague in Egypt and India.

A new journal of hypnotism has commenced publication in France, the *Mouvement Psychique*, the official organ of the Paris Institute of Psychical Sciences.

Professor Behring is recipient of a title of nobility, conferred on the occasion of the 200th anniversary of the Kingdom of Prussia.

Among the deaths abroad occur the names of Dr. A. Spengler, of Davos, and Dr. J. Lehmann, of Copenhagen, the latter noted for his studies in hygiene and tuberculosis.

South American Women Practitioners.—The first woman to take the degree of medicine in Peru is Señorita Laura Rodriguez, who received her diploma in 1900. Ana Galvez, of Bogota, graduated in Switzerland some years ago, and returned to practice in Colombia, where she has acquired a wide reputation for her cures. In Chili, Eloisa Inzunza received her degree in medicine at Santiago in 1887, and has been practising with success ever since, according to the *Cronica Medica*, of Lima.

Tetanus from Anti-Diphtheria Serum.—During the last few months there have been an unusual number of cases of diphtheria in Italy, and antidiphtheria serum has been extensively used, nearly all derived from the Milan Institute of Serotherapy, in charge of Belfanti. According to the *Münchener Med. Woch.*, eight patients in one small town were injected with the serum and were convalescing when, the sixth to ninth day after the injection, symptoms of fulminating tetanus appeared and all but one died. Similar experiences were reported from other points, with a total of thirteen deaths. The boards of health of Milan and Rome met in emergency session, and the institute was closed. The contaminated serum was all of a certain series of 305 vials, delivered November 29, and 230 of them have been recovered, as the prefect of Milan telegraphed at once to all who had purchased the serum. It has been impossible to produce tetanus in animals inoculated with the blood of any of the patients who died, and no tetanus bacilli can be found in the recovered serum. There is no official standardizing of the serum in Italy as in Germany.

The Plague Abroad.—Passed Assistant Surgeon A. R. Thomas, who was detailed by the surgeon-general, U. S. M.-H. S., to investigate the cases of plague reported on board the *Friary*, at Hull, England, has reported that there were five deaths among the crew of that vessel, three of which were undoubted cases of plague as shown by necropsy, while the other two were probably cases, though no necropsy was held in either. The patients had no glandular enlargements, and the symptoms were so like influenza that the first two were thought to be this affection. The ship was 17 days out from Alexandria, Egypt, before the first case developed, but several rats and a cat died aboard ship before it developed. [See also London letter, this week.—ED.] According to the *British Medical Journal*, a case of plague was reported in Constantinople on January 11, and a strict quarantine of twelve days at once ordered on all vessels arriving at the mouth of the Danube from the Turkish capital. Traffic was also suspended on railway lines between Bucharest and the Black Sea ports. Reports also indicate that the disease is prevalent at Smyrna, and that of 14 persons attacked by the disease in one house, 11 died up to January 20. In Hamburg the steamship *Bergamon*, which arrived there on January 15, was placed in quarantine as the rats on board were found infected with plague. In India the deaths from this disease during the week ending January 5 numbered 2298, a marked increase over the corresponding week of last year, when there were only 1370 deaths so registered. More than one-half the number for all India occurred in Bengal, i. e., 1374, and during the week ending January 10, Mauritius reported 20 new cases of plague and 9 deaths, for the succeeding week 15 new cases and 16 deaths. In a report to the surgeon-general, U. S. M.-H. S., from Hongkong, China, Assistant-Surgeon J. W. Kerr reports, for the ten months ended Oct. 31, 1900, 1082 cases of bubonic plague with 1034 deaths. It is interesting to note that of the 6 Europeans attacked by this disease only 1 died. The method of loading ships will give some idea of how easy it is for ships to become infected while in that port. A large part of the cargo is brought direct from Canton, China, in "junks," a sort of house-boat in which the lowest class of Chinese live. From these junks the cargo is carried on the outgoing ship, and in this way can infect the rats on shipboard, or rats from the junks can get aboard. As evidence that these floating homes are infected, numbers of bodies dead from plague have been found floating in the harbor. Only a few days before Dr. Kerr's attention was called to the body of a child lying on top of a buoy in the harbor. And several instances are given where coolies engaged in loading have dropped in the harbor and been drowned, and on bacteriologic examination were found to present evidences of advanced plague infection; they were no doubt ambulatory cases overcome by overexertion.

Queen Victoria's Last Illness.—The following, from the *Lancet* of January 26, is of interest concerning the late Queen: Her health for the past twelve months had been failing, with symptoms mainly of a dyspeptic kind accompanied by impaired general nutrition, periods of insomnia, and later by occasional slight and transitory attacks of aphasia, the latter suggesting that the cerebral vessels had become damaged, although her general arterial system showed remarkably few signs of age. The constant brain work through a long life of royal responsibilities, and the imperial events, domestic sorrows, and anxieties which have crowded into her later years, may no doubt be held in some measure to account for this discrepancy between the cerebral and general vessel nutrition. The thoracic and abdominal organs showed no signs of disease. The dyspepsia which tended to lower her originally robust constitution was especially marked during her last visit to Balmoral. It was there that she first manifested distinct symptoms of brain fatigue and lost notably in weight. These symptoms continued at Windsor, where in November and December slight aphasic symptoms were first observed, always of an ephemeral kind and unattended by any motor paralysis. Although it was judged best to continue the negotiations for her proposed visit to the continent in the spring, it was distinctly recognized by her physicians and by those in closest personal attendance on her that these arrangements were purely provisional, it being particularly desired not to discourage her majesty in regard to her own health by suggesting doubts as to the feasibility of the change abroad to which she had been looking forward. The Queen suffered unusual fatigue from the journey to Osborne on December 18, showing symptoms of nervous agitation and restlessness which lasted for two days, but afterward improved for a time both in appetite and nerve tone in response to more complete quietude than she had hitherto consented to observe. A few days before the final illness transient but recurrent symptoms of apathy and somnolence with aphasic indications and increasing feebleness gave great uneasiness to her physician. On Wednesday, January 16, she showed increasing symptoms of cerebral exhaustion. By an effort of will, however, she would for a time, as it were, command her brain to work and the visitor of a few minutes would fail to observe the signs of cerebral exhaustion. On Thursday the exhaustion was more marked, with considerable drowsiness; and a slight flattening was observed on the right side of the face. From this time the aphasia and facial paresis, although incomplete, were permanent. On Friday she was a little brighter, but on Saturday evening, the 19th, there was a relapse of the graver symptoms which, with remissions, continued until the end. It is important to note that notwithstanding the great bodily weakness and cerebral exhaustion the heart's action was steadily maintained to the last; the pulse at times evincing increased tension, but being always regular and of normal frequency. The temperature was normal throughout. In the last few hours of life paresis of the pulmonary nerves set in, the heart beating steadily to the end. Beyond the slight right facial flattening there was never any motor paralysis, and except for the occasional lapses mentioned, the mind can not be said to have been clouded. Within a few minutes of her death the Queen recognized the several members of her family.

GENERAL.

Plague Investigation in San Francisco.—The recent appointment by the U. S. Treasury Department of Drs. F. G. Novy, of Ann Arbor, Simon Flexner, of the University of Pennsylvania, and L. F. Barker, of the University of Chicago, to investigate the plague in San Francisco has created consternation among those who have been denying the existence of plague there, as is evidenced by the special message presented by the governor to the legislature on the 31st ult. The governor and his medical advisors are said to have cause to fear the result which an independent investigation by such men will bring forth. The "appropriate action" which the governor, "impelled by his sense of public duty," relies on the discretion of the legislature to take, is embodied in three bills which have emanated from his office. The first adds three new sections to the Penal Code. The first section is as follows: "Any person who willfully or maliciously exposes, handles, or otherwise deals with any disease germs, bacilli, cultures, organisms or seeds of disease, or sources from which diseases may be communicated, for the purpose of communicating such disease, or with the intent to spread or communicate any infectious or contagious disease, or who negligently exposes, handles or otherwise deals with the same in a manner calculated to endanger the public health, or to result in the spread of an infectious or contagious disease, is guilty of a felony and on conviction thereof shall be punished by imprisonment in a state prison for a term of not less than one year nor more than ten years, or by a fine of not less than $500 nor more than $5000, or by both such fine and imprisonment." Another new section provided by the bill reads as follows: "Any person or any officer or member of any association, board, committee or corporation who publishes by any writing or printing that Asiatic cholera or the bubonic plague exists, or has recently existed within this state, unless the State Board of Health thereof has first determined such to be the fact and has entered a record of such determination at length upon the minutes of the board, is guilty of a felony." But it is in the second bill that the significant feature of this movement comes prominently into light. In this bill an appropriation of $100,000 is provided to be expended by the State Board of Health, *under the direction of the governor*, for the prevention of the introduction of Asiatic cholera, bubonic plague, smallpox or other contagious or infectious disease within this state, and for their suppression in case of their origin or introduction. It is provided that the claims for expenditures shall be audited by the board of examiners, except when, in the opinion of the governor, "an emergency arises which demands or necessitates the immediate use of the money, and in that case it is provided that the controller must draw his warrant in the name of the governor, without auditing, for sums not exceeding $1000 at any time the governor may direct." The object of the third bill is to center in the governor and the State Board of Health most of the power that now belongs to the local boards, and to reestablish the state quarantine service in San Francisco that has been supplanted by the Federal authorities. The effect on local boards of health will be to practically wipe them out of existence in any case of emergency, or to make them no more than sanitary police to assist the state board. Whenever they find anything they must stand aside, leaving the state board in charge. Orders were given that these bills be rushed through with all possible speed. To further this, type-written copies of the bills were furnished committee members in order that it might not be necessary to await the usual time for printing. [As we go to press we learn that the bill appropriating $100,000 has passed the assembly.]

LONDON.

The Epidemic of Arsenical Poisoning from Beer Drinking.

Though the outbreak of arsenical poisoning due to beer drinking, which occurred principally in Manchester, and to a less extent in Liverpool and others parts of the north of England, and also in some of the midland counties, has not disclosed any new symptom of arsenical poisoning, yet the observations on such a large scale reveal certain facts not at all generally known as to the frequency or otherwise of the symptoms produced by chronic arsenical intoxication. The most valuable contribution on this subject is the paper read by Dr. E. S. Reynolds at the Royal Medical and Chirurgical Society of London. In my last letter Dr. Reynolds' important discovery that the epidemic of "peripheral neuritis" in Manchester was due to arsenic in the beer has already been fully described in these columns. The patients complained of a variety of symptoms, such as pain in the feet and limbs, a feeling of pins and needles, tingling in the soles, general weakness, difficulty of walking, swollen feet, vomiting, and diarrhea. The aspect of the patients was so typical that a diagnosis could be made at sight by those accustomed to see the cases. There was a puffiness, especially about the eyelids, and a deep crimson color of the face. Of the numerous skin eruptions, erythromelalgia was perhaps the commonest. It consisted of painful red swelling of the feet and hands. The erythema was most intense at the edges, the center of the palm being almost exempt. The pain was so marked that the patients could not sleep. The red patches were followed by keratosis of the hands and feet, scales being exfoliated so plentifully that a 2-ounce bottle could be filled in a short time. This keratosis was very important in the diagnosis in fair-haired persons, because in them pigmentation did not occur. If a fair-haired person had such keratosis and peripheral neuritis there was a strong presumption of arsenical poisoning. There were also scarlatiniform and morbilliform erythematous rashes. The first began like scarlatina, with a collaret around the neck. Sometimes there were papular, sometimes vesicular and bullous eruptions. These rashes came on as late as six weeks after ceasing to drink the beer. Pigmentation was very common and the cases showed that the received description is not quite correct. Though some showed islets of normal skin in a generalized pigmentation, such were not always present. In 21 cases herpes was observed in various situations. The heart was very seriously affected. It became dilated and there was sometimes edema of the feet and chest wall. Arsenic was found in the urine in many cases as long as two weeks after ceasing to take contaminated beer. It was also excreted in the milk. In some cases the temperature was elevated.

Appointment of a Royal Commission.

A royal commission has been appointed to investigate the epidemic of arsenical poisoning. It will consist of Lord Kelvin, Sir W. Hart Dyke, Sir W. S. Church (president of the Royal College of Physicians), Prof. T. E. Thorpe (government analyst), Mr. H. Cosmo Bonsor and Dr. B. A. Whitelegge (H. M. chief inspector of factories). The instructions to the commissioners are to ascertain: 1. The amount of recent exceptional sickness and death attributable to arsenical poisoning. 2. Whether such sickness and death has been due to arsenic in beer or in other articles of food or drink. 3. By what safeguards arsenical poisoning from food may be prevented.

Enormous Pancreatic Cyst Simulating Ascites.

At the Clinical Society, Dr. Sidney Phillips read notes of this case. A man, aged 22, was kicked in the abdomen by a horse. He became subject to attacks of acute abdominal pain, and after five months was quite emaciated and had an enormously distended abdomen, dull everywhere except in the stomach's area. Ascites with peritoneal adhesions was thought probable. After 145 ounces of clear fluid had been removed by Southey's tubes, without improvement, laparotomy was performed, and a large quantity of fluid, like that of ascites, removed. Death occurred a few days later. The necropsy showed that the fluid had been contained in a thin-walled pancreatic cyst occupying almost the whole abdominal cavity. The cyst originated in the head of the pancreas, with which it communicated by an opening one-sixth inch in diameter. The remarkable point in the case was the unusual character of the fluid, which had a specific gravity of 1002, quite clear, and closely resembled ascitic fluid.

Plague at Hull.

Plague has again visited our shores. This time the important seaport of Hull is the point of attack. A steamer arrived on January 10 from Alexandria, having touched at Algiers on the voyage. Three days before the vessel arrived one of the crew was taken suddenly ill and died after forty-eight hours' illness. Being so near the port the captain, instead of consigning the body to the deep, brought it to land. The vessel was inspected by the port sanitary authorities, and the man having apparently died from natural causes, and there being no more sickness on board, suspicions were not aroused and the vessel was allowed to enter the dock and discharge the cargo in the usual manner. But on the 12th two of the crew sickened. The medical officer of health was called in and diagnosed influenza complicated by pneumonia. Two more of the crew sickened on the 15th. The four died. Post-mortem examination of two of the bodies again failed to show anything inconsistent with the diagnosis of influenza and pneumonia, but owing to the suspicious circumstances the viscera were forwarded to the well-known expert, Dr. Klein, for bacteriologic examination. He has found that the disease was plague. All necessary precautions to prevent the spread of the disease have been taken. Two of the bodies have been cremated and the authorities await permission to cremate the other two. The local government board has dispatched an inspector, who is investigating the matter.

Angina Epiglottidea Anterior.

JERSEY CITY, N. J., Jan. 23, 1901.

To the Editor:—Having had a case of angina epiglottidea anterior, or acute epiglottitis, I read with interest the account of this malady, in THE JOURNAL of January 18, by Dr. Clement F. Theisen, Albany, N. Y. My one case may, however, throw more light on this peculiar ailment, and it is with this belief I offer it for publication. J. MORGAN JONES, M.D.

REPORT OF CASE.

Miss K. C. M., aged 21 years, was taken suddenly ill, Jan. 6, 1901, with lancinating pains at the base of the tongue, and with difficult deglutition. She grew rapidly worse until January 9, when she could swallow absolutely nothing; pain at the base of the tongue was much more severe, and she had some temperature and was slightly constipated. She was unable to assume a recumbent posture, on account of dyspnea, and was obliged to resort to oral breathing, to improve that condition. At this time they decided to see a physician, and called on a brother practitioner, at his office. From the history of the trouble, he diagnosed the case as tonsillitis, and prescribed accordingly. The patient continued to get worse, and sent for the physician to call at her home, January 10, but as he was unable to attend, I was asked to take charge. On seeing her for the first time, she was sitting in a chair, the body inclined forward, her mouth open, and with an anxious facial expression. On being asked why she sent for a physician I was told that she was subject to tonsillitis, and supposed she was undergoing a similar attack at that time, only much worse, and feared her throat was going to become entirely closed.

The throat was enveloped in strips of salt pork, covered by a flannel bandage. There was considerable submaxillary lymphatic involvement, which one could see as well as feel. However, the patient gave a tubercular history, and admitted the presence of glandular enlargement for several months. Inspection of the oral cavity and pharyngeal vault revealed absolutely no evidence of inflammation anywhere, and for a moment I was nonplussed. But, as the patient repeatedly touched herself about the inferior border of the thyroid cartilage, and insisted that movements of the tongue were very painful, and that she could still swallow nothing, I made a laryngoscopic examination, and found the epiglottis very much inflamed, of a uniform scarlet hue, also considerably enlarged. There was slight extension of the inflammation to the vocal cords, and also to the aryteno-epiglottic folds. Rectal temperature was 101.5., the tongue slightly coated, gray but moist. The pulse was 88, regular, and tension normal. Parenthetically, I was informed she had been treated for a valvular cardiac lesion, for a year; but it was not discoverable to me.

Treatment.—I prescribed calomel, gr. 1/10, every half hour for ten doses; it had to be dissolved in one-half dram of water, and then kept in the mouth, as the patient could not swallow, even to that extent. In addition, inhalations of turpentine vapor were ordered, to be inhaled through a cone every hour; also a cold spray of hydrogen dioxid and water, equal parts, to be used every hour. The strips of salt pork were discontinued, and hot water fomentations used, to be changed as soon as they would feel cool, during the daytime. Upon retiring, for I encouraged the reclining posture, a cold water pack was applied and left *in situ* till morning. Jan. 11, 1901, the bowels moved freely twice, showing characteristics of the calomel purgation. Hot water fomentations were discontinued, but otherwise treatment continued unchanged. By night, there was a diminution in the size of the lymphatics, the patient felt slight improvement, and was able to swallow about one-half an ounce of milk. Saturday, January 12, there was very little soreness remaining, and she could swallow liquids with very little discomfort. On the 13th her condition was entirely relieved, and, contrary to advice, she ate a hearty dinner, experiencing no deleterious effects, save that la grippe developed next day, from which recovery was prompt and uneventful.

Association News.

Committee on National Legislation.

The Committee on National Legislation of the AMERICAN MEDICAL ASSOCIATION hereby calls a meeting in annual conference at Washington, D. C., on Feb. 20 and 21, 1901, at 11 a.m., at the Arlington Hotel, to consider various medical matters now pending in the national Congress of the United States, and any other medical matters of local interest to societies.

Angina Epiglottidea Anterior.

Jersey City, N. J., Jan. 23, 1901.

To the Editor:—Having had a case of angina epiglottidea anterior, or acute epiglottitis, I read with interest the account of this malady, in The Journal of January 18, by Dr. Clement F. Theisen, Albany, N. Y. My one case may, however, throw more light on this peculiar ailment, and it is with this belief I offer it for publication. J. Morgan Jones, M.D.

REPORT OF CASE.

Miss K. C. M., aged 21 years, was taken suddenly ill, Jan. 6, 1901, with lancinating pains at the base of the tongue, and with difficult deglutition. She grew rapidly worse until January 9, when she could swallow absolutely nothing; pain at the base of the tongue was much more severe, and she had some temperature and was slightly constipated. She was unable to assume a recumbent posture, on account of dyspnea, and was obliged to resort to oral breathing, to improve that condition. At this time they decided to see a physician, and called on a brother practitioner, at his office. From the history of the trouble, he diagnosed the case as tonsillitis, and prescribed accordingly. The patient continued to get worse, and sent for the physician to call at her home, January 10, but as he was unable to attend, I was asked to take charge. On seeing her for the first time, she was sitting in a chair, the body inclined forward, her mouth open, and with an anxious facial expression. On being asked why she sent for a physician I was told that she was subject to tonsillitis, and supposed she was undergoing a similar attack at that time, only much worse, and feared her throat was going to become entirely closed.

The throat was enveloped in strips of salt pork, covered by a flannel bandage. There was considerable submaxillary lymphatic involvement, which one could see as well as feel. However, the patient gave a tubercular history, and admitted the presence of glandular enlargement for several months. Inspection of the oral cavity and pharyngeal vault revealed absolutely no evidence of inflammation anywhere, and for a moment I was nonplussed. But, as the patient repeatedly touched herself about the inferior border of the thyroid cartilage, and insisted that movements of the tongue were very painful, and that she could still swallow nothing, I made a laryngoscopic examination, and found the epiglottis very much inflamed, of a uniform scarlet hue, also considerably enlarged. There was slight extension of the inflammation to the vocal cords, and also to the aryteno-epiglottic folds. Rectal temperature was 101.5., the tongue slightly coated, gray but moist. The pulse was 88, regular, and tension normal. Parenthetically, I was informed she had been treated for a valvular cardiac lesion, for a year; but it was not discoverable to me.

Treatment.—I prescribed calomel, gr. 1/10, every half hour for ten doses; it had to be dissolved in one-half dram of water, and then kept in the mouth, as the patient could not swallow, even to that extent. In addition, inhalations of turpentine vapor were ordered, to be inhaled through a cone every hour; also a cold spray of hydrogen dioxid and water, equal parts, to be used every hour. The strips of salt pork were discontinued, and hot water fomentations used, to be changed as soon as they would feel cool, during the daytime. Upon retiring, for I encouraged the reclining posture, a cold water pack was applied and left *in situ* till morning. Jan. 11, 1901, the bowels moved freely twice, showing characteristics of the calomel purgation. Hot water fomentations were discontinued, but otherwise treatment continued unchanged. By night, there was a diminution in the size of the lymphatics, the patient felt slight improvement, and was able to swallow about one-half an ounce of milk. Saturday, January 12, there was very little soreness remaining, and she could swallow liquids with very little discomfort. On the 13th her condition was entirely relieved, and, contrary to advice, she ate a hearty dinner, experiencing no deleterious effects, save that la grippe developed next day, from which recovery was prompt and uneventful.

Association News.

Committee on National Legislation.

The Committee on National Legislation of the American Medical Association hereby calls a meeting in annual conference at Washington, D. C., on Feb. 20 and 21, 1901, at 11 a.m., at the Arlington Hotel, to consider various medical matters now pending in the national Congress of the United States, and any other medical matters of local interest to societies.

H. L. E. Johnson, M.D.
Chairman Committee on National Legislation.

Chairmen of Committees of the American Medical Association.

Dr. J. W. Chamberlin, Lowry Arcade, St. Paul, Minn., badges.

Dr. J. F. Fulton, Lowry Arcade, St. Paul, Minn., on arrangements.

Dr. C. Williams, 145 West 5th street, St. Paul, Minn., banquets.

Dr. C. A. Wheaton, Lowry Arcade, St. Paul, Minn., on finance.

Dr. H. L. Taylor, Lowry Arcade, St. Paul, Minn., general exhibits.

Dr. H. H. Kimball, Dayton Building, St. Paul, Minn., meeting places.

Dr. Burnside Foster, Lowry Arcade, St. Paul, Minn., entertainments.

Dr. Edw. Boeckmann, Lowry Arcade, St. Paul, Minn., pathological exhibits.

Dr. J. A. Quinn, corner 4th street and Wabasha, St. Paul, Minn., transportation.

Dr. Harry O'Brien, Endicott Arcade, St. Paul, Minn., pro-
grams and publications.

Dr. J. T. Rogers, Lowry Arcade, St. Paul, Minn., halls and meeting places.

Dr. E. J. Abbott, Endicott Arcade, St. Paul, Minn., bureau of information.

Dr. J. B. Brimhall, Seven Corners, St. Paul, Minn., registration.

Dr. Arthur Sweeney, Lowry Arcade, St. Paul, Minn., hotel arrangements.

New Members.

The following is a list of new members of the A. M. A. for January, 1901.

ALABAMA.

Brothers, Philip H., Zula.
Baker, D. H., Birmingham.
Due, Malvern N., Birmingham.
Pettus, Claude, Monrovia.
Hudson, W. H., LaFayette.
Sledge, Wm. H., Mobile.

CALIFORNIA.

Evans, Geo. H., San Francisco.
Wilbur, Ray L., San Francisco.
Tooley, L. P., Willows.
Ketcham, L. Y., San Diego.
Haynes, J. R., Los Angeles.

GEORGIA.

Lovvorn, R. M., Bowdon.
Roberson, G. W., Macon.
Barron, Robt. B., Macon.

ILLINOIS.

Stiver, R. J., Lena.
Knoppenberger, H., Macomb.
Schowengerdt, W. E., Champaign.
Dixon, Wm. A., Decatur.
Wells, Wm. H., Monmouth.
Merriman, H. P., Chicago.
Novak, F. J., Chicago.
Martin, Albert R., Chicago.
Wagner, Henry E., Chicago.
Beehler, L. L., Chicago.
Dombrowski, Paul, Peoria.
Corwin, A. M., Chicago.
McKinney, John G., Quincy.
Yolton, John L., Bloomington.
Fringer, G. W., Pana.
Fullenwider, J. A., Champaign.
Heisz, Emily J., Chicago.

NAME OMITTED FROM PUBLISHED LIST OF MEMBERS IN SEPTEMBER.

Gillespie, T. W., Losant, Ill.

INDIANA.

Howat, W. F., Hammond.
Moore, E. P., South Bend.
Oyler, Wm. A., Argos
Holland, P. C., Bloomington.

INDIAN TERRITORY.

Kennedy, Samuel G., Tulsa.

IOWA.

Rector, Albert E., Spirit Lake.
Allen, Manning L., Tama.
Wedel, J. R., Vincennes.
Boice, J. C., Washington.
Prentice, G. L., Searsboro.

KENTUCKY.

Smith, Joseph E., Bardstown.
Foster, Wm. E., Owenton.
Fugitt, Walter W., Burtonville.

LOUISIANA.

Girard, Percy M., Lafayette.
McGuire, Marion H., New Orleans.
Gaydon, Agrippa, Norwood.
Alison, Jacob S., Swartz.
Stephens, Jos. S., Natchitoches.
Blum, Henry N., New Orleans.

MASSACHUSETTS.

Weston, George D., Springfield.
Hill, Edgar D., Plymouth.
Dickson, Richard E., Granby.
Hood, Mary G., Newton Center.
McDonald, Wm. J., Boston.
Thorndike, Augustus, Boston.
Shisler, Wm. H., Boston.
Clement, Geo. C., Haverhill.

MARYLAND.

Hocking, G. H., Baltimore.
Grieves, C. J., Baltimore.
Johnson, Thos. B., Frederick.
Orrison, J. E., Baltimore.

MICHIGAN.

Baldwin, Fred'k A., Ann Arbor.
Greene, M. Clayton, Lowell.
Brehm, Theo., Negaunee.
Campbell, J. F., Lansing.
Cornell, D. B., Saginaw.
Otis, F. J., Battle Creek.
Schmalzriedt, Theo., Woodmere.

MINNESOTA.

Holte, H., Crookston.
Shimonek, A., St. Paul.
Archibald, F. N., Atwater.
Maloy, G. E., St. Cloud.
Lumley, W. A., Renville.
Shrader, E. E., Watertown.
McCarthy, Wm. J., Madelia.
Stuart, J. H., Minneapolis.
Lonsdale, J., Royalton.
Law, A. A., Minneapolis.
Curran, G. R., Worthington.
De La Barre, Wm., Minneapolis.
Grivelli, Carl T., Young America.
Wilson, Warren, Northfield.

Smith, Bryant, Milwaukee.

Book Notices.

Ringworm in the Light of Recent Research. By Malcolm Morris, Surgeon to the Skin Department, St. Mary's Hospital. Price, $2.00. London, Paris and Melbourne: Cassell & Co. 1898.

This appears in the form of an artistic cloth-bound monograph of 137 pages, illustrated by a colored frontispiece and twenty-two photomicrographs of stained specimens and cultures of the ringworm fungi. The reproductions are of a good order. The subject is introduced by a brief historical treatment and a rehearsal of the parasitic theory of the disease. Gruby is credited with the discovery of the Microsporon audouini in 1843, while in 1844 Malmsten discovered the trichophyton fungus. It is explained that through a confusion of terms the discovery fell into disrepute and was entirely forgotten until Sabouraud in 1892 established the parasitic nature of the disease and the plurality of its fungi. The doctrine of Sabouraud is clearly set forth, and his conclusions in the main adopted, the criticisms being offered that the French investigator divides the fungi into too many varieties, and is too positive concerning the clinical differences of the various types of infection. The results of other modern investigators are summarized, and the author offers the results of his own examination of 126 consecutive cases. The hairs of all cases were stained by a modified Gram method—original with the author—and many cultures were made on Sabouraud's maltose agar. The cultural results in the main corroborate those of the French writer. It is suggested, however, that the fine cultural differences of Sabouraud are not essential.

Treatment and prophylaxis receive detailed and satisfactory attention.

No criticism is to be offered on the clearness and easy style of the contributors.

Manual of Pathology, Including Bacteriology, the Technic of Post-mortems, and Methods of Pathologic Research. By W. M. Late Coplin, M.D., Professor of Pathology and Bacteriology, Jefferson Medical College, Philadelphia; Pathologist to Jefferson Medical College Hospital and to the Philadelphia (Blockley) Hospital; Bacteriologist to the Pennsylvania State Board of Health. Third Edition, revised and enlarged. 350 Illustrations and 7 Colored Plates. Octavo. Pp. 846. Price, $3.50 net. Philadelphia: P. Blakiston's Son & Co. 1900.

Including, as this book does, bacteriology, the technique of post-mortem examinations, methods of research in pathology, general and special pathology, it is quite self-evident that the 846 pages of which it consists can only give the most important facts of the subjects mentioned. We believe that the work is quite reliable as far as it goes. In some places the classification is somewhat peculiar, thus there is a separate chapter devoted to mucous membranes in the section on special pathology, and then we find that the different mucous membranes are considered again in connection with the organs of respiration and alimentary canal, etc. In the section on technic, there is a large number of illustrations which show the names of the manufacturers in large letters, so that this part of the book looks quite like an instrument catalogue. The type is large and clear; the paper is of a high grade, and many of the illustrations are quite satisfactory.

Terapia Delle Malattie Dell' Infanzia ad uso di medici e studenti del Dott. Prof. Cesare Cattaneo, Libero docente di Clinica Medica Pediatrica alla R. Università di Parma. Cloth. Pp. 507. Milan, Italy: Urico Hoepli. 1901.

This little volume on the diseases of children differs somewhat in its plan from the average of similar publications. It is a work of treatment almost exclusively, and in alphabetic arrangement. The author accepts as probable, and takes for granted, that the reader is well posted as to the symptoms of the diseases, so, after a few remarks on causation and prognosis, passes at once to the therapeutics of the disorder and its complications. The work contains a large number of prescriptions given according to the Italian Pharmacopeia, but readily transposable and intelligible for the most part to the American practitioner even though the text accompanying them is not. The volume seems to be, in its compass, and with its limitations above noted, a very satisfactory handling of its particular subject.

Diseases of the Heart, Blood-Vessels, Lymphatics, Blood, and Ductless Glands. A Wall Chart. Published by M. J. Breitenbach Co., New York.

This chart gives the chief points of each disorder under the heads of causation, general symptoms, physical signs by inspection, palpation, auscultation, depression, blood change, pulse characteristics, the complications and sequelæ also noted. So far as we are able to see, the chart is a reliable statement of the main diagnostic points of these diseases, and will be a very convenient office adjunct to a physician for occasional or daily reference.

Married.

Arthur E. Gillette, M.D., to Miss Mayme Jones, both of Cincinnati, Ohio, January 24.

Horace Hall, M.D., Tepasals, Mexico, to Miss Camilla Scott, of Dallas, Texas, January 24.

G. W. Launspach, M.D., Fulton, S. Dak., to Miss Mary Anderson, of Dubuque, Iowa, January 16.

Frank Gray Ketchum, M.D., New York City, to Miss Mary Myers, of Lonaconing, Md., January 24.

F. Cullen Welty, M.D., Cleveland, Ohio, to Miss Eleanor Wood, of San Francisco, Cal., February 7.

Willis Alonzo Bird, M.D., Theney, Texas, to Miss Sara Priscilla Burdeshaw, of Kinsey, Tenn., January 16.

James Hardy Pittman, M.D., Jacksonville, Fla., to Miss Myrtice Barnett Cason, of Marietta, Ga., January 24.

William Fulford Sappington, M.D., of the house staff of the Maryland University Hospital, to Miss Florence Valiant Robertson, of Baltimore, at Elmira, N. Y., January 24.

Deaths and Obituaries.

Martin Hagan, M.D., Starling Medical College, Columbus, Ohio, 1859, Los Angeles, Cal., died at his home in that place, January 23, from apoplexy, aged 68. After service in the Civil War he practiced in St. Paul, Minn., until 1881, when he was placed in charge of the asylum for the insane of the Hawaiian Islands. In 1884 he moved to Los Angeles, and three years later was made health officer. He did efficient work in the smallpox epidemic of 1887-88.

Henry J. Herrick, M.D., Rush Medical College, Chicago, 1861, died from uremia, after an illness of about one year, at his home in Cleveland, Ohio, January 28, aged 67. He was a member of The American Medical Association, for many years professor of state medicine and hygiene in the medical department of Western Reserve University, and surgeon-general of Ohio, during Governor Foraker's administration.

William H. Nevison, M.D., Western Reserve University, Cleveland, Ohio, 1887, and a member of its faculty, died at Lakeside Hospital, Cleveland, Ohio, January 27, from pulmonary tuberculosis. *He was 37 years old. At a meeting* of the faculty of the medical department of the university, January 30, resolutions laudatory of the deceased and expressing regrets and sympathy at his early death, were adopted.

Homer Octavius Jewett, M.D., New York University, 1843, died at his home in Cortland, N. Y., from pneumonia. He was one of the founders of the New York State Medical Association, before which he read many papers. He also early identified himself with The American Medical Association, and was in active practice until about a month before his death.

Charles W. Stevens, M.D., Harvard Medical School, 1870, died at his residence in Charlestown, Mass., January 25, from diphtheria, at the age of 65. He served as city physician and as surgeon on one of the steamship lines between Boston and Liverpool, and was a member of the Massachusetts Academy of Medicine.

Armstrong P. Houston, M.D., Jefferson Medical College, Philadelphia, 1854, of Clarksville, Ga., died in Atlanta, Ga., January 27, while on his way to Florida for his health, aged 69. He practiced at Clarksville for forty years and served during the Civil War as a surgeon on the Confederate side.

Henry L. Stickel, M.D., Jefferson Medical College, Philadelphia, 1873, died in Harrisburg, Pa., January 24, from tuberculosis, aged 48. He served as surgeon in the army and was consulting surgeon of the Harrisburg Hospital.

Isaac Ryall, M.D., *Trinity Medical College, Toronto, 1855,* medical health officer of Hamilton, Ont., died on January 20, from hemorrhage of the stomach. For twenty-six years he was Hamilton's health officer. He was also surgeon to the Thirteenth Regiment at the time of the fenian raid.

S. D. M. Byrd, M.D., Oglethorpe Medical College, Savannah, Ga., 1856, died suddenly at his home in Scranton, S. C., January 21. He served on the Confederate side in the Civil War, rising to the rank of lieutenant-colonel, and was also state representative and senator for several terms.

Frederick G. Bloom, M.D., died at his home in Martinsburg, Pa., January 23, aged 79. He was one of the oldest graduates of the University of Pennsylvania, and had practiced in Martinsburg for more than half a century.

Albert G. Priest, M.D., Jefferson Medical College, Philadelphia, 1852, died suddenly from apoplexy, January 24, at his home in Shelbyville, Mo., where he had practiced for nearly fifty years. His age was 72 years.

David V. Waite, M.D., Geneva Medical College, Geneva, N. Y., 1851, who had practiced medicine for more than forty years in and around Rockton, Ill., died at his home in that place, January 26, aged 76.

Dennis H. Reardon, M.D., Western Reserve, Cleveland, Ohio, 1883, of Elmira, N. Y., was found dead, January 27. An overdose of chloroform, which he was in the habit of inhaling, was the cause.

Wesley W. Barkwell, M.D., Detroit College of Medicine, 1889, who practiced in Chicago until tuberculosis forced him to go to San Jose, Cal., in 1898, died at Tucson, Ari., January 28, aged 38.

Oliver Newton Murdock, M.D., College of Physicians and Surgeons, Keokuk, Iowa, 1876, died January 29, at his home in Minneapolis, Minn., after a short illness from la grippe, aged 47.

Nathan H. Raynor, M.D., University of Pennsylvania, Philadelphia, 1879, died at his residence in Philadelphia, January 25, after an illness of two months, from Bright's disease, aged 45.

William W. Parker, Jr., M.D., University College of Medicine, Richmond, Va., 1899, died at the Virginia Hospital, Richmond, after an illness of four weeks, from typhoid fever, January 24.

Edson K. Smith, M.D., Dartmouth Medical College, Hanover, N. H., 1891, died at his home in Poultney, Vt., after an illness of two weeks, from typhoid fever, January 24, aged 46.

Frederick C. McCarthy, M.D., Harvard Medical School, 1899, of Malden, Mass., died from typhoid fever at the Mas*sachusetts General Hospital, Boston, January* 21, aged 28.

John D. Kremien, M.D., formerly a practicing physician of Baltimore, and a member of the Medical and Chirurgical Faculty of Maryland, died January 23, from typhoid fever.

Erskine E. Hamilton, M.D., College of Physicians and Surgeons, New York City, 1892, recently died from Bright's disease, at his home in Springfield, Mass., aged 34.

William Langdon Simpson, M.D., Medical School of Maine, Brunswick, 1879, died from the effects of a bullet-wound in the head, in New York City, January 26.

William Foster Harvey, M.D., Medical College of Ohio, for many years a practitioner in Hendricks County, Ind., died at his home in Indianapolis, January 27, aged 75.

John Thompson, M.D., Bellevue Hospital Medical College, 1871, died from pneumonia, after an illness of four days, at his home in Amherst, Va., January 23, aged 61.

John H. Miller, M.D., Castleton Medical College, Castleton, Vt., 1859, formerly a resident of New Bremen, N. Y., died at his home in Burbank, Cal., January 24, aged 66.

J. Ranlet Smith, M.D., Vermont Medical College, Woodstock, 1845, died at his residence in Gloucester, Mass., January 25, after an illness of several years, aged 79.

Walter W. Worley, M.D., St. Louis Medical College and Bellevue Hospital Medical College. died after a long illness, January 22, at his home in Ursa, Ill., aged 37.

Henry W. Bryan, M.D., University of Pennsylvania, 1895, died at his home in Wilmington, Del., from pneumonia after an illness of four days, January 27, aged 31.

William D. Craig, M.D., Rush Medical College, Chicago, 1850, who had practiced for forty years in Aledo, Ill., died at his home in that city, January 23, aged 71.

John H. O'Brien, M.D., New York University, 1887, died at his home in Pittsburg, Pa., January 28, after an illness of six weeks, from Bright's disease, aged 41.

Charles C. Allen, M.D., Missouri Medical College, St. Louis, 1850; Bellevue Hospital Medical College, 1872, died at his home in Chillicothe, Ill., January 23, aged 75.

Almon V. Thompson, M.D., Medical School of Maine, Brunswick, 1874, died from Bright's disease, January 25, at his home in Beaver Falls, Pa., aged 56.

J. Stuart Leech, M.D., Jefferson Medical College, Philadelphia, 1841, the oldest physician in Chester County, died January 23, at Downington, Pa., aged 87.

John F. McGrew, M.D., College of Physicians and Surgeons, Baltimore, Md., 1888, died from consumption at his home in Finleyville, Pa., January 27, aged 40.

Frank Wertz, M.D., University of Pennsylvania, 1866, died at his home in Longswamp Township, Berks County, Pa., January 18, from apoplexy, aged 64.

Grafton Marsh Bosley, M.D., University of Maryland, 1847, of Towson, Md., died at the Church Home and Infirmary, Baltimore, January 26, aged 75.

Frederick S. Nelson, M.D., University of the South, Sewanee, Tenn., 1900, died January 27 from tuberculosis, at Newmarket, N. J., aged 37.

John A. Keith, M.D., Medical College of the State of South Carolina, Charleston, S. C., 1881, died at his home in Lucknow, S. C., January 23.

Louis R. Warren, M.D., College of Physicians and Surgeons, New York City, 1880, died recently at his home, Orange Ridge, Braidentown, Fla.

Theodore D. C. Miller, M.D., Bellevue Hospital Medical College, New York, 1866, died at his home, New York City, January 29, aged 59.

Arthur W. Langley, M.D., Medical School of Maine, Brunswick, 1891, died suddenly at his home in Kennebunkport, Me., January 23, aged 35.

Edward James Marshall, M.D., University of Pennsylvania, Philadelphia, 1867, died at his home in Northbrook, January 28, aged 60.

Henry W. Holman, M.D., Jefferson Medical College, Philadelphia, 1855, at his home in Inez, Va., from pneumonia, January 23, aged 71.

James Seth, M.D., University of Maryland, 1865, died January 26, at his home near McDaniel, Md., where he had practiced for 35 years.

Andrew J. Norris, M.D., College of Physicians and Surgeons, Iowa, 1870, died at his home in Ten Mile, Mo., January 28, aged 56.

Guthrie Rider Winder, M.D., Long Island College Hospital, Brooklyn, 1898, of Brooklyn, N. Y., died January 25, aged 26.

Joseph E. M. Chamberlaine, M.D., University of Maryland, 1849, died at his residence in Easton, Md., January 30, aged 74.

Luther P. Hess, M.D., Medical College of Indiana, Indianapolis, 1881, died at his home in Oakland, Cal., January 30, aged 57.

Shadrach L. Ferree, M.D., Medical College of Indiana, Indianapolis, 1870, died at his home in Indianapolis, January 30, aged 71.

Paul Jencke, M.D., Missouri Medical College, 1878, died from pneumonia, January 29, at his home in Linn, Mo.

Stephen Chandler Griggs, M.D., New York University, 1849, of Brooklyn, New York, died February 1, aged 81.

Seneca M. Bain, M.D., Tulane University, New Orleans. La., 1861, died at his home in Gatesville, Texas, January 22.

Miscellany.

Neurasthenia Not a Prerogative of the Cultured Classes.—Petren of Lund writes to the *Deu. Ztft. f. Nervenheilkunde* that it is an error to assume that neurasthenia is less frequent among the lower classes, the peasants, of Europe than among the cultured. He doubts whether modern civilization is responsible for the increase in nervous degeneration.

Traumatic Etiology of Malignant Tumors.—A recent thesis reviews the material in the Goettingen clinic for nineteen years—a total of 1767 cases of malignant tumors—and notes that in 45 there was a possibility of traumatic origin. This possibility was very slight in 21, which leaves only 24 in which the trauma had actual etiologic significance. This is a very small proportion compared with those reported by others: Wolff, 68 in 462 cases, or 14.7 per cent.; Liebe 28 in 271, or 13.3 per cent.; Rapok, 109 in 553, or 19.7 per cent.; Lengnick, 24 in 579, or 4.1 per cent., while Kempf, the author of the thesis in question, reviewed in the *Cbl. f. Chir.*, found only 45 in 1767, or 2.5 per cent.

Operating by Light from Automobile.—A correspondent of the *Boston Medical and Surgical Journal* (January 26) reports a new use for the electric automobile. A laparotomy having been necessitated in the evening, at a private house, where only open burning lights were available, and etherization was therefore dangerous, he attached a couple of incandescent lamps to his motor battery by insulated wire, thus performing the operation with ease and safety. He offers this experience as a suggestion of a possible enhanced value of the electric automobile to physicians, not only as a magazine of light when needed, but also for cauteries, therapeutic applications of currents, etc., and a similar use of the automobile has been made by others (Caldwell: The Journal, February 2. p. 344.)

Differentiation of Cancer and Liver Abscess by the Blood.—Boinet states that when the leucocytes—especially the polynucleated—are six to ten times more numerous than normally, it is a strong supporting testimony of the presence of an abscess in the liver. The *Sem. Méd.*. of January 2 cites cases in which the assumption of an abscess of this kind from the condition of the blood was confirmed by operation. Hartmann also calls attention to the blood as a means of differentiating carcinoma of the stomach. In one case in which the clinical evidence of carcinoma was unquestioned the contradictory testimony of the blood was disregarded and the stomach found intact. The health of the patient has been good since. In another case an ulcer of the stomach was assumed, but the blood and the laparotomy showed the lesion to be a carcinoma.

Therapeutics.

Treatment of Hereditary Syphilis of Nose and Throat.

In addition to the constitutional treatment, Casselberry advises attention to the bowels, diet and general health. As a local application to the ulcers he recommends the following:

R.	Iodini			
	Acidi tannici			
	Potassii iodidi, āā	ʒi	4	
	Glycerini	℥ss	16	
	Aquæ, q. s. ad	℥i	32	

M. Sig.: Apply to the ulcers directly with a cotton swab.

Pyle recommends the following in local treatment of hereditary syphilis:

R.	Acidi borici	gr. v		33
	Pot. permanganatis	gr. i		06
	Aquæ destil	℥i	32	

M. Sig.: Apply locally.

Or,

R.	Acidi carbol	gr. i		06
	Sodii bicarb	gr. vi		36
	Acidi borici	gr. v		30
	Aquæ	℥i	32	

M. Sig.: Locally to nasal passages.

The child should be placed in the nurse's lap and the naso pharynx plugged by means of a temporary sponge, the head slightly raised and the nose washed out with a fine syringe, spray or douche, too much force not being used.

OZENA DEPENDENT ON HEREDITARY SYPHILIS.

R.	Arsenici iodidi	gr. iii		18
	Hydrarg. biniodidi	gr. v		30
	Potassii iodidi	ʒi	4	
	Aquæ destil	℥iv	128	

M. Sig.: Four drops three times a day, to be increased according to age.

Fetid Rhinitis.

G. M. Leffert, in *Med. News*, recommends the daily use of the anterior and posterior nasal syringe, the removal of hard crusts with the forceps and washing thoroughly with one of the following alkaline and antiseptic solutions until all offensive secretions have been removed:

R.	Sodii boratis	ʒi	4	
	Glycer. acidi carbol	ʒiss	6	
	Aquæ destil	Oi	500	

M. Sig.: To be used as an atomizer.

Either of the following prescriptions may be used in the same manner:

R.	Acidi salicylici	gr. x		66
	Sodii bicarb	ʒi	4	
	Aquæ destil	Oi	500	

Or,

R.	Sodii boratis	ʒi	4	
	Sol. potas. permangan.—1 per cent	ʒiss	6	
	Aquæ destil	Oi	500	

To overcome the dryness of the mucous membrane follow the cleansing with a spray of liquid albolene.

Euquinin in Acute Nasal Catarrh.

Merck's Archives recommends euquinin in the following combination in acute rhinitis:

AS A PILL.

R.	Euquinin	gr. xxx	2	
	Liq. potassii arsenitis	m. x		66
	Solutionis atropinæ—1 per cent	m. iv		25
	Ext. gentianæ	gr. xx	1	33
	Pulveris acaciæ, q. s.			

M. Ft. pilulæ No. xii. Sig.: Take one pill every three hours.

AS A TABLET.

℞.	Euquinin	gr. x		66
	Atropinæ sulphatis	gr. 1/30		002
	Morphinæ sulphatis	gr. ss		03
	Camphoræ	gr. x		66

M. Ft. tabellæ No. xx. Sig.: One every half hour for six doses, or until throat feels dry, then one every two or three hours.

Euquinin is slightly bitter and can be given in doses of one and a half times that of quinin sulphate, administered in powder, capsule, soup, milk or cocoa.

Local Treatment of Diphtheria.

Sheffield recommends the following combinations in treatment of diphtheria:

℞.	Papainæ—glycerin extract	ʒiv	16	
	Acidi carbol.			
	Pulv. camphoræ, āā	gr. viii		50
	Alcoholis, q. s. ad sol.			
	Glycerini, q. s. ad	℥ii	64	

M. Sig.: This is to be applied to the throat by means of a cotton swab every two hours until abatement of the symptoms, then less frequently.

Or.

℞.	Hydrogeni peroxidi	ʒiv	16	
	Sodii boratis	ʒii	8	
	Glycerini	℥ii	64	
	Aquæ rosæ, q. s. ad	℥iv	128	

M. Sig.: One tablespoonful to be instilled into the nose every two hours while the diphtheric membrane is present.

Treatment of Follicular Pharyngitis.

Kyle states that, in the early stages of clergyman's sore throat, where permanent structure change has not taken place, he is in the habit of administering drugs that are eliminated by the mucous membrane. Under such circumstances he recommends the following:

℞.	Phosphori	gr. 1/6		01
	Iodini	gr. ii		12
	Bromini	gr. ii		12
	Vini xerici	℥ii	64	

M. Sig.: One teaspoonful three times a day.

A local application of chromic acid in twenty per cent. solution to each follicle, touching only a few at one time, may be made being careful to dry the part afterward with a piece of dry absorbent cotton. He recommends as a local application to the entire surface the following:

℞.	Olei pini sylvestris			
	Olei eucalypti, āā	gtt. v		30
	Menthol	gr. iv		25
	Tinct. benzoini	℥i	32	

M. Sig.: Apply locally every other day to stimulate the mucous membrane and promote resolution.

Treatment of Tuberculosis.

Flich, in *Med. Record*, states that in his opinion drugs containing iodin are the best, and that they are best given by inunction. He further states that the essential oils, and especially peppermint and thyme, unfit the tissues as soil for the propagation of the bacilli. Mendel recommends the following combination in treatment of tuberculosis:

℞.	Olei thymi			
	Olei eucalypti			
	Olei cinnamomi, āā	gtt. lxxx	52	
	Iodoformi	gr. xv	1	
	Olei olivæ steril	℥iiiss	112	

M. Sig.: Introduce 45 minims into the trachea by means of a long-curved syringe.

Nocturnal Incontinence of Urine.

Stumpf, in *Jour. of Med. and Science*, recommends that the child lie in such a position that the head is lower than the hips, so that the urine will not flow into the urethra, and thus irritate and excite the urethral sphincter. He states that after such postural treatment for three weeks the usual position in bed may be resumed.

Guaiacol in Chronic Cystitis.

Gabriel Colin, in *Jour. de Méd. de Paris*, advises the following formula in chronic cystitis of tuberculous origin:

℞.	Guaiacol	ʒi	4	
	Ol. amygdalæ dulcis—sterilized	ʒiiss	80	

M. Sig.: Inject from a quarter to half a teaspoonful into the bladder once or twice a day.

Chronic Prostatitis.

Freudenberg, in the same journal, recommends the following suppository:

℞.	Ichthyol	gr. v to xii		33--72
	Olei theobromatis	gr. l	3	33

M. Ft. suppository. Sig.: One such suppository to be inserted twice a day, night and morning, after evacuation of the bowels. If a movement occurs in the middle of the day, a third suppository may be used after it.

Treatment of Varicose Veins.

Woodward, in the *Clinique*, states that obliteration of the vein should first be made and if eczema exists over the area of induration and edema he advises the parts to be washed in a solution of bichlorid and carbolic acid morning and evening, and the following ointment applied:

℞.	Olei picis	ʒss	2	
	Zinci oxidi	℥ii	64	

M. Sig.: Apply locally night and morning.

If an exudate and blebs appear the following is preferable:

℞.	Acidi tannici	gr. v		30
	Bismuthi subnitratis	ʒss	2	
	Lanolini	℥i	32	

M. Sig.: Apply locally.

Where radical measures are refused by the patient, or in old subjects, the recumbent posture and elastic bandages will improve the condition; in ulcerations dusting powders of boric acid, iodoform, bismuth subnitrate. A paste made of mild chlorid of mercury and sodium chlorid stimulates granulation tissue.

Infantile Colic.

Dr. P. F. Barbour, in *Pediatrics*, states that in colic of infants the use of warm enemata will generally remove the gas. The enema may contain a few drops of turpentine or half a teaspoonful of glycerin. Hot applications should be applied to the abdomen and the feet and hands kept warm. He also recommends small amounts of hot whisky and water with a drop of the essence of peppermint and a little sodium bicarbonate by the mouth. One of the following combinations is also recommended:

℞.	Spts. ammon. arom	m. vi		36
	Sodii bicarb	gr. xii		72
	Syr. rhei aromatici	ʒi	4	
	Aquæ cari	℥iss	48	

M. Sig. One teaspoonful as required.

Or,

R.	Tinct. asafetidæ	m. xv	1	
	Olei cajuputi	m. ii		12
	Mag. carbonatis	ʒss	2	
	Syr. acaciæ	℥ss	16	
	Aquæ anisi	℥iss	48	

M. Sig.: One teaspoonful as required.

Enterocolitis (Mucomembranous) in Adults.

℞.	Magnesiæ (calcined)			
	Sulphuris loti			
	Potassii bitartratis, āā	ʒv	20	

M. Sig.: One teaspoonful before each meal.

Enteritis of Nursing Infants.

R.	Tannigeni	gr. x		66
	Acidi lactici	gr. xxx	2	
	Syrupi simplicis	℥i	32	
	Aquæ destil., q. s. ad	℥iii	96	

M. Sig.: One teaspoonful before each nursing.

—*Clinica Moderna.*

Tannigen should be given in much larger doses in order to derive the proper benefit from it. It can be given in doses ranging from three to five grains to infants.

Treatment of Atonic Ulcers by Hot Irrigations.

Kindler, in the *Centralblatt f. Chir.*, has treated with good results chronic ulcers by irrigations of two liters of water, as hot as could be borne, flowing with a drop of six feet. These irrigations were repeated two or three times a day and followed by dry rubbing with powdered iodoform or bismuth subgallate. He noted that chronic leg ulcers, perforating ulcers of tabes, the slow and progressive erosions of tertiary syphilis and phagadenic chancroids were thus cured in a very short time.

Medicolegal.

Not Liable for Unhealthful Condition of Lockup.—The Supreme Court of Iowa holds, in the case of Lahner vs. the Incorporated Town of Williams, that a municipal corporation is not liable in damages for injury to a person's health caused by his incarceration over night, without food or water or suitable protection against the cold, in a filthy and unhealthful lockup, under an arrest without legal cause or excuse, the acts complained of having been done by officers of the corporation in an attempt to enforce its police regulations.

Making Mismanagement of Physician a Defense to Crime.—In the homicide case of the State of Iowa vs. Wood it appeared that certain injuries had been inflicted on the 11th of the month. Up to the 6th of the following month the victim of the injuries had improved in health. Then his physician temporarily left the state. Another was called on the 11th, and soon thereafter empyema set in, resulting in death on the 24th. The defendant insisted that the evidence tended to show that, but for mismanagement on the part of this second physician, or those caring for the injured man, he might have recovered: and that the jury should have been instructed, if they so found, that the defendant could not be convicted of manslaughter. But not so thinks the Supreme Court of Iowa. In affirming a judgment of conviction, it holds that to warrant escape for the killing, the subsequent mismanagement or neglect must have been the sole cause of death, and that the jury was rightly instructed that, if the injuries inflicted by the defendant directly contributed to produce empyema, causing death, he was guilty of taking the life of the deceased, while if these did not so contribute, he could not be convicted of murder or manslaughter. No principle, it declares, is better settled than that he who, by his wrongful act, accelerates or hastens death, or contributes to its cause, is guilty of homicide; and whether this be murder of manslaughter necessarily depends on the intent or motive by which the person making it was actuated.

Charitable Hospital Owned by Individual is Taxable.—The state constitution of North Dakota provides that "the legislative assembly shall, by a general law, exempt from taxation property used exclusively for school, religious, cemetery, or charitable purposes." The legislature, in describing the property exempt from taxation, enumerated: "All buildings belonging to institutions of purely public charity, including public hospitals, together with the land actually occupied by such institutions, not leased or otherwise used with a view to profit," etc. Now, the constitutional provision, the Supreme Court of North Dakota holds, Engstad vs. Grand Forks County, does not of its own force operate to exempt any property from taxation, is not self-executing; and, under the statute, real estate which is used exclusively for purposes of purely public charity, but which is not owned by an "institution," is not exempt from taxation. Hence, it holds that there is no law in the state which exempts from taxation a hospital, and the land upon which it is erected, when the same is conducted solely by one individual, who owns the same, and who operates it for public charity exclusively. In fact, it declares that real estate which belongs to but one individual, a natural person, can not, under any circumstances, be entitled to exemption from taxation under the statute. Nor does it consider the statute repugnant to the constitution because it is narrower in its terms, or because it limits the exemption of real estate used for charitable purposes to such real estates as is devoted to purely public charitable uses, and then only to such as belongs to an "institution."

Insanity Produced by Epilepsy.—In the murder case of State vs. Wright, where one of the special defenses was insanity produced by epilepsy, the Supreme Court of Iowa not only says that alienists universally recognize epilepsy as one of the most frequent causes of mental disturbance, but that the possible effect of epilepsy on the general mental condition is within the knowledge of all courts who have come in contact with the disease in the trial of cases involving mental unsoundness. Continuing, it states that, in determining the mental condition of a person at a given time, it becomes of the utmost importance to know his mental condition before that time, and to know also the effect of previous attacks of the disease, and whether or not they have left traces of an alteration of the intellectual functions. And, indeed, it declares, it takes it to be the rule that, in all cases involving the question of mental capacity, it is competent to go into the minutest details of the personal history of the one who is claimed to be mentally afflicted. Likewise, it deems it proper to show his physical and mental condition after the transaction in question. It also holds that, the defendant having shown by a certain physician that he had treated a sister of defendant for epilepsy, it was error not to allow him to show when. Moreover, one of the questions for the jury to determine being whether the defendant was drunk or in a fit of epilepsy when the fatal shot was fired, the court holds that the testimony of a witness offered to show the defendant's appearance, color of his face, etc., when drinking, and within a short time thereafter, was improperly refused. It holds that if the defendant was at the time temporarily insane, and his mental condition was caused by epilepsy, and if the attack may have been produced by drug in the liquor given him, it could not be said that he would be responsible for his act, though there may have been intoxication. But it does not consider the victim's dying declaration, that he did not think the defendant intended to shoot him, but thought that he was crazy, admissible in evidence, there being nothing in the evidence to show that this was his deliberate opinion, based on any facts which he had recited, the statement being but an opinion to which he could not have testified without giving to the jury the facts upon which he based his opinion.

United States Supreme Court on Cigarettes.—The Supreme Court of the United States holds constitutional, in the case of Austin vs. the State of Tennessee, the act of that state making it a misdemeanor punishable by a fine of not less than $50 for any person, firm, or corporation to sell, offer to sell, or to bring into the state for the purpose of selling, giving away, or otherwise disposing of, any cigarettes, cigarette paper, or substitute for the same. It first, however, insists that whatever product has from time immemorial been recognized by custom or law as a fit subject for barter or sale, particularly if its manufacture has been made the subject of Federal regulation and taxation, must be recognized as a legitimate article of commerce, although it may to a certain extent be within the police power of the states, and that of this class of cases is tobacco. It admits that the effects of tobacco may be injurious to some, but thinks that its extensive use over practically the entire globe is a remarkable tribute to its popularity and value. Anyhow, it is clearly of the opinion that tobacco can not be classed with diseased cattle or meats, decayed fruit, or other articles, the use of which is a menace to the health of the entire community. Cigarettes, it goes on to say, are but one of the numerous manufactures of tobacco, and it can not take judicial notice of the fact that it is more noxious in this form than in any other. Again, it says that they do not seem until recently to have attracted the attention of the public as more injurious than other forms of tobacco; nor, it says, is it prepared to take judicial notice of any special injury resulting from their use or to indorse the opinion of the Supreme Court of Tennessee that "they are inherently bad and bad only." At the same time, it declares that it should be shutting its eyes to what is constantly passing before them were it to affect an ignorance of the fact that a belief in their deleterious effects, particularly upon young people, has become very general, and that communications are constantly finding their way into the public press denouncing their use as fraught with great danger to the youth of both sexes. And, without undertaking to affirm or deny their evil effects, it thinks it within the province of the legislature to say how far they may be sold, or to prohibit their sale entirely, after they have been taken from the original packages or have left the hands of the importer, provided no discrimination be used as against such as are imported from other states, and that there be no reason to doubt that the act in question is designed for the protection of the public health. Moreover, it holds that a paper package of 3 inches in length and 1½ inches in width, containing ten cigarettes, is not an original package protected by the Constitution of the United States against any interference by the states while in the hands of the importer. Nor, it says, in the course of its opinion, can it deny to the legislature the power to impose restrictions upon the sale of noxious or poisonous drugs, such as opium and other similar articles, extremely valuable as medicines, but baneful to the habitual user.

Permanency in Practice as Evidence of Qualification.—The Supreme Court of Iowa holds, in the case of State vs. Blair, that the nature and extent of the qualifications required of practitioners of medicine are primarily for the determination of the legislature. No objection can be urged because of their severity, if appropriate to the profession, and attainable by reasonable study and application. They deprive no one of the right to practice medicine so long as all that is exacted is that every one who assumes to do so shall be possessed of the requisite knowledge and skill, and that this be evidenced by a certificate of the board designated by the state to ascertain his fitness. Nor does it consider unconstitutional the provision of the Iowa Code making one of the ways in which qualification might be evidenced prior to Jan. 1, 1899, that the physician had "been in practice in this state for five consecutive years, three of which time shall have been in one locality." It says that the statute recognizes that actual experience in the practice of medicine tends to render the physician capable. Success therein denotes the possession of learning and skill. Continuing in the profession several years in a particular locality indicates a degree of merit not likely to be found in a person moving from place to place. Indeed, it declares, it is a matter of general observation that the itinerant doctor, roving about, without remaining in one locality longer than a few days or weeks, is usually wanting in honesty, and too frequently but a charlatan or quack. Besides, such a professional residence affords the opportunity of becoming known by neighbors, and, if lacking in capacity or character, obstacles may be interposed to the issuance of a certificate; for it must not be overlooked that, notwithstanding continuous practice in one place, a certificate may be denied, owing to incompetency or immorality. In practical operation, the law admits those to practice who have followed the profession at one place long enough to acquire knowledge through experience in the profession, and to become known, unless want of capacity or good character affirmatively appears. Others must be examined or present diplomas. It makes a distinction recognized in all the affairs of life. And if, within the ordinary experience of men, and as a matter of common observation, physicians of learning, skill, and character are generally permanently located, and seldom change the place where their profession is followed, as appears to be true, the court says it can discover no tenable reason why this circumstance might not be treated by the legislature as evidence of qualification under the statute. In short, it thinks the distinction of the Iowa Code in this regard neither arbitrary nor unreasonable, but in harmony with common knowledge of differences which ordinarily exist between persons following the medical profession who have a permanent locus in quo, and those who do not. It adds that it is not unmindful that the Supreme Court of New Hampshire, in construing a somewhat similar statute, has held to the contrary, appearing to have grounded its conclusion on the erroneous assumption that permanency in the practice in a locality furnishes no evidence of qualification. But this, it says it has undertaken here to demonstrate, is not warranted.

Guaiacol in Chronic Cystitis.

Gabriel Colin, in *Jour. de Méd. de Paris*, advises the following formula in chronic cystitis of tuberculous origin:

℞.	Guaiacol	ʒi	4	
	Ol. amygdalæ dulcis—sterilized	ʒiiss	80	

M. Sig.: Inject from a quarter to half a teaspoonful into the bladder once or twice a day.

Chronic Prostatitis.

Freudenberg, in the same journal, recommends the following suppository:

℞.	Ichthyol	gr. v to xii		33--72
	Olei theobromatis	gr. l	3	33

M. Ft. suppository. Sig.: One such suppository to be inserted twice a day, night and morning, after evacuation of the bowels. If a movement occurs in the middle of the day, a third suppository may be used after it.

Treatment of Varicose Veins.

Woodward, in the *Clinique*, states that obliteration of the vein should first be made and if eczema exists over the area of induration and edema he advises the parts to be washed in a solution of bichlorid and carbolic acid morning and evening, and the following ointment applied:

℞.	Olei picis	ʒss	2	
	Zinci oxidi	℥ii	64	

M. Sig.: Apply locally night and morning.

If an exudate and blebs appear the following is preferable:

℞.	Acidi tannici	gr. v		30
	Bismuthi subnitratis	ʒss	2	
	Lanolini	℥i	32	

M. Sig.: Apply locally.

Where radical measures are refused by the patient, or in old subjects, the recumbent posture and elastic bandages will improve the condition; in ulcerations dusting powders of boric acid, iodoform, bismuth subnitrate. A paste made of mild chlorid of mercury and sodium chlorid stimulates granulation tissue.

Not Liable for Unhealthful Condition of Lockup.—The Supreme Court of Iowa holds, in the case of Lahner vs. the Incorporated Town of Williams, that a municipal corporation is not liable in damages for injury to a person's health caused by his incarceration over night, without food or water or suitable protection against the cold, in a filthy and unhealthful lockup, under an arrest without legal cause or excuse, the acts complained of having been done by officers of the corporation in an attempt to enforce its police regulations.

Making Mismanagement of Physician a Defense to Crime.—In the homicide case of the State of Iowa vs. Wood it appeared that certain injuries had been inflicted on the 11th of the month. Up to the 6th of the following month the victim of the injuries had improved in health. Then his physician temporarily left the state. Another was called on the 11th, and soon thereafter empyema set in, resulting in death on the 24th. The defendant insisted that the evidence tended to show that, *but for mismanagement on the part of this second physician, or* those caring for the injured man, he might have recovered: and that the jury should have been instructed, if they so found, *that the defendant could not be convicted of manslaughter.* But not so thinks the Supreme Court of Iowa. In affirming a judgment of conviction, it holds that to warrant escape for the killing, the subsequent mismanagement or neglect must have been the sole cause of death, and that the jury was rightly instructed that, if the injuries inflicted by the defendant directly contributed to produce empyema, causing death, he was guilty of taking the life of the deceased, while if these did not so contribute, he could not be convicted of murder or manslaughter. No principle, it declares, is better settled than that he who, by his wrongful act, accelerates or hastens death, or contributes to its cause, is guilty of homicide; and whether this be murder of manslaughter necessarily depends on the intent or motive by which the person making it was actuated.

Charitable Hospital Owned by Individual is Taxable.—The state constitution of North Dakota provides that "the legislative assembly shall, by a general law, exempt from taxation property used exclusively for school, religious, cemetery, or charitable purposes." The legislature, in describing the property exempt from taxation, enumerated: "All buildings belonging to institutions of purely public charity, including public hospitals, together with the land actually occupied by such institutions, not leased or otherwise used with a view to profit." etc. Now, the constitutional provision, the Supreme Court of North Dakota holds, Engstad vs. Grand Forks County, does not of its own force operate to exempt any property from taxation, is not self-executing; and, under the statute, real estate which is used exclusively for purposes of purely public charity, but which is not owned by an "institution," is not *exempt from* taxation. Hence, it holds that there is no law in the state which exempts from taxation a hospital, and the land upon which it is *erected, when the same is conducted* solely by one individual, who owns the same, and who operates it for public charity exclusively. In fact, it declares that real estate which belongs to but one individual, a natural person, can not, under any circumstances, be entitled to exemption from taxation under the statute. Nor does it consider the statute repugnant to the constitution because it is narrower in its terms, or becvause it limits the exemption of real estate used for charitable purposes to such real estates as is devoted to purely public charitable uses, and then only to such as belongs to an "institution."

Insanity Produced by Epilepsy.—In the murder case of State vs. Wright, where one of the special defenses was insanity produced by epilepsy, the Supreme Court of Iowa not only says that alienists universally recognize epilepsy as one of the most frequent causes of mental disturbance, but that the possible effect of epilepsy on the general mental condition is within the knowledge of all courts who have come in contact with the disease in the trial of cases involving mental unsoundness. Continuing, it states that, in determining the mental condition of a person at a given time, it becomes of the utmost importance to know his mental condition before that time, and to know also the effect of previous attacks of the disease, and whether or not they have left traces of an alteration of the intellectual functions. And, indeed, it declares, it takes it to be the rule that, in all cases involving the question of mental capacity, it is competent to go into the minutest details of the personal history of the one who is claimed to be mentally afflicted. Likewise, it deems it proper to show his physical and mental condition after the transaction in question. It also holds that, the defendant having shown by a certain physician that he had treated a sister of defendant for epilepsy, it was error not to allow him to show when. Moreover, one of the questions for the jury to determine being whether the defendant was drunk or in a fit of epilepsy when the fatal shot was fired, the court holds that the testimony of a witness offered to show the defendant's appearance, color of his face, etc., when drinking, and within a short time thereafter, was improperly refused. It holds that if the defendant was at the time temporarily insane, and his mental condition was caused by epilepsy, and if the attack may have been produced by drug in the liquor given him, it could not be said that he would be responsible for his act, though there may have been intoxication. But it does not consider the victim's dying declaration, that he did not think the defendant intended to shoot him, but thought that he was crazy, admissible in evidence, there being nothing in the evidence to show that this was his deliberate opinion, based on any facts which he had recited, the statement being but an opinion to which he could not have testified without giving to the jury the facts upon which he based his opinion.

United States Supreme Court on Cigarettes.—The Supreme Court of the United States holds constitutional, in the case of Austin vs. the State of Tennessee, the act of that state making it a misdemeanor punishable by a fine of not less than $50 for any person, firm, or corporation to sell, offer to sell, or to bring into the state for the purpose of selling, giving away, or otherwise disposing of, any cigarettes, cigarette paper, or substitute for the same. It first, however, insists that whatever product has from time immemorial been recognized by custom or law as a fit subject for barter or sale, particularly if its manufacture has been made the subject of Federal regulation and taxation, must be recognized as a legitimate article of commerce, although it may to a certain extent be within the police power of the states, and that of this class of cases is tobacco. It admits that the effects of tobacco may be injurious to some, but thinks that its extensive use over practically the entire globe is a remarkable tribute to its popularity and value. Anyhow, it is clearly of the opinion that tobacco can not be classed with diseased cattle or meats, decayed fruit, or other articles, the use of which is a menace to the health of the entire community. Cigarettes, it goes on to say, are but one of the numerous manufactures of tobacco, and it can not take judicial notice of the fact that it is more noxious in this form than in any other. Again, it says that they do not seem until recently to have attracted the attention of the public as more injurious than other forms of tobacco; nor, it says, is it prepared to take judicial notice of any special injury resulting from their use or to indorse the opinion of the Supreme Court of Tennessee that "they are inherently bad and bad only." At the same time, it declares that it should be shutting its eyes to what is constantly passing before them were it to affect an ignorance of the fact that a belief in their deleterious effects, particularly upon young people, has become very general, and that communications are constantly finding their way into the public press denouncing their use as fraught with great danger to the youth of both sexes. And, without undertaking to affirm or deny their evil effects, it thinks it within the province of the legislature to say how far they may be sold, or to prohibit their sale entirely, after they have been taken from the original packages or have left the hands of the importer, provided no discrimination be used as against such as are imported from other states, and that there be no reason to doubt that the act in question is designed for the protection of the public health. Moreover, it holds that a paper package of 3 inches in length and 1½ inches in width, containing ten cigarettes, is not an original package protected by the Constitution of the United States against any interference by the states while in the hands of the importer. Nor, it says, in the course of its opinion, can it deny to the legislature the power to impose restrictions upon the sale of noxious or poisonous drugs, such as opium and other similar articles, extremely valuable as medicines, but baneful to the habitual user.

Permanency in Practice as Evidence of Qualification.—The Supreme Court of Iowa holds, in the case of State vs. Blair, that the nature and extent of the qualifications required of practitioners of medicine are primarily for the determination of the legislature. No objection can be urged because of their severity, if appropriate to the profession, and attainable by reasonable study and application. They deprive no one of the right to practice medicine so long as all that is exacted is that every one who assumes to do so shall be possessed of the requisite knowledge and skill, and that this be evidenced by a certificate of the board designated by the state to ascertain his fitness. Nor does it consider unconstitutional the provision of the Iowa Code making one of the ways in which qualification might be evidenced prior to Jan. 1, 1899, that the physician had "been in practice in this state for five consecutive years, three of which time shall have been in one locality." It says that the statute recognizes that actual experience in the practice of medicine tends to render the physician capable. Success therein denotes the possession of learning and skill. Continuing in the profession several years in a particular locality indicates a degree of merit not likely to be found in a person moving from place to place. Indeed, it declares, it is a matter of general observation that the itinerant doctor, roving about, without remaining in one locality longer than a few days or weeks, is usually wanting in honesty, and too frequently but a charlatan or quack. Besides, such a professional residence affords the opportunity of becoming known by neighbors, and, if lacking in capacity or character, obstacles may be interposed to the issuance of a certificate; for it must not be overlooked that, notwithstanding continuous practice in one place, a certificate may be denied, owing to incompetency or immorality. In practical operation, the law admits those to practice who have followed the profession at one place long enough to acquire knowledge through experience in the profession, and to become known, unless want of capacity or good character affirmatively appears. Others must be examined or present diplomas. It makes a distinction recognized in all the affairs of life. And if, within the ordinary experience of men, and as a matter of common observation, physicians of learning, skill, and character are generally permanently located, and seldom change the place where their profession is followed, as appears to be true, the court says it can discover no tenable reason why this circumstance might not be treated by the legislature as evidence of qualification under the statute. In short, it thinks the distinction of the Iowa Code in this regard neither arbitrary nor unreasonable, but in harmony with common knowledge of differences which ordinarily exist between persons following the medical profession who have a permanent locus in quo, and those who do not. It adds that it is not unmindful that the Supreme Court of New Hampshire, in construing a somewhat similar statute, has held to the contrary, appearing to have grounded its conclusion on the erroneous assumption that permanency in the practice in a locality furnishes no evidence of qualification. But this, it says it has undertaken here to demonstrate, is not warranted.

Societies.

COMING MEETINGS.

Tri-State Medical Association of the Carolinas and Virginia, Richmond, Va., Feb. 26, 1901.

Medical Society of the Missouri Valley, Omaha, Neb., March 21, 1901.

Hillsboro County (Fla.) Medical Society.—Dr. Louis A. Bize, Tampa, has been elected president of this Society; Dr. George H. Alltree, Port Tampa City, vice-president, and Dr. John S. Helms, Palmetto, secretary and treasurer.

Brashear Medical Society.—At the annual meeting of this Society, held in Bardstown (Ky.), Dr. Aloysius G. Blincoe was elected president; Dr. William W. Ray, Springfield, vice-president, and Dr. Wiley Rogers, Taylorsville, secretary and treasurer.

St. Joseph County (Ind.) Medical Society.—At the meeting of this Society, in South Bend, January 28, Dr. Fred P. Eastman, was elected president; Dr. George W. Van Benschoten, vice-president; Dr. Harry F. Mitchell, secretary, and Dr. Charles M. Butterworth, treasurer, all of South Bend.

King County (Wash.) Medical Society.—The twelfth annual meeting and banquet of this Society was held at Seattle, January 21. The following officers were elected: Dr. Caspar W. Sharples, president; Dr. John B. Loughary, vice-president; Dr. George H. Randell, secretary, and Dr. Frank M. Carroll, treasurer, all of Seattle.

Newport (R. I.) Medical Society.—The Society held its annual meeting January 18, and Dr. Henry Ecroyd was elected president; Dr. William S. Sherman, vice-president; Dr. Mary E. Baldwin, secretary; Dr. Douglas P. A. Jacoby, treasurer; Dr. Thomas A. Kenefick, curator; Dr. Charles W. Stewart, bacteriologist, and Dr. F. Jerome Davis, librarian.

Utah County (Utah) Medical Society.—At the meeting of this Society, January 10, a committee of three was appointed to co-operate with the medical societies of Salt Lake and Weber counties in presenting the proper and legitimate information to members of the legislature concerning a law governing vaccination and the powers of the boards of health.

Savannah (Ga.) Medical Society.—At the annual meeting of this Society, January 10, the following officers were elected: Dr. John W. Daniel, president; Dr. Ralston Lattimore, vice-president; Dr. Ralph M. Thomson, recording secretary; Dr. J. Lawton Hiers, corresponding secretary; Dr. J. L. Farmer, treasurer, and Dr. William E. Fitch, librarian.

Fox River Valley Medical Society.—The annual meeting of this Society was held in Green Bay, Wis., January 2. The following officers were elected: Dr. Abbott W. Slaughter, Green Bay, president; Dr. Alphonse M. Kersten, De Pere and Charles D. Boyd, Kaukauna, vice-presidents; Dr. James S. Reeve, Appleton, secretary and treasurer, and Dr. Herbert B. Tanner, Kaukauna, censor.

Blair County (Pa.) Medical Society.—This Society met for its annual dinner at Altoona, January 24, and elected the following officers: Dr. Samuel P. Glover, president; Drs. Orr H. Shaffer and Robert J. Hillis, vice-presidents; Dr. J. Wesley Rowe, recording secretary; Dr. Mary Irwin Thompson, corresponding secretary and reporter, and Dr. William S. Ross, treasurer, all of Altoona.

Associated Physicians of Long Island (N. Y.)—The third annual meeting of this Association was held in Brooklyn, January 26. The following officers were elected: Dr. William B. Gibson, Huntington, president; Drs. Calvin F. Barber, Brooklyn, James S. Cooley, Glen Cove, and William H. Ross, Brentwood, vice-presidents; Dr. James C. Hancock, Brooklyn, secretary, and Dr. John P. Heyen, Northport, treasurer.

Jackson County (Mich.) Medical Society.—This Society completed its organization at Jackson, January 24, by adopting a constitution and by-laws in conformity with the "Code of Ethics of The American Medical Association," and electing the following officers: Dr. Albert E. Bulson, president; Dr. Martha C. Strong, vice-president; Dr. A. H. Wilton, secretary, and Dr. Frederick W. Rogers, treasurer, all of Jackson.

Denver and Arapahoe Medical Society.—At the annual meeting held in Denver, Colo., January 8, the following officers were elected: Dr. Horace G. Wetherill, president; Henry Sewall, vice-president; Dr. Walter Holden, secretary; Dr. George H. Stover, financial secretary; Dr. Edwin J. Rothwell, treasurer, and Drs. Edgar P. Hershey, Walter A. Jayne, Edward Jackson, Josiah N. Hall, and Leonard Freeman, board of censors, all of Denver.

Southwestern Medical Association of Texas, New Mexico, Arizona and Mexico.—This Association met at El Paso, Texas, January 23, for organization, and elected Dr. Charles T. Race, El Paso, Texas, president; Drs. Samuel D. Swope, Deming, N. M., T. H. Swayne, Chihuahua, Mexico, and Hiram W. Fenner, Tucson, Ariz., vice-presidents; Dr. John J. Gilbride, El Paso, Texas, secretary, and Dr. Stephen T. Turner, El Paso, Texas, treasurer.

Rensselaer County Medical Association.—The members of the Second District Branch of the New York State Medical Association, 43 in number, met in Troy, January 10, and organized the Rensselaer County Medical Association, adop by-laws and elected the following officers: Dr. Charles S. Al Rensselaer, president; Dr. Matthew B. Hutton, of Valley F. vice-president, and Dr. Frederick F. A. Smith, Troy, se and treasurer.

Orleans Parish (La.) Medical Society.—At the of this Society, held January 26, Dr. E. Denegre Martin, Orleans, read a paper on spinal anesthesia, in which he vocated the theory that disturbance of the cerebrospinal causes the unpleasant after-effects of this mode of anesth and suggested the use of small quantities of more conc solutions—4 minims of a 5 per cent. solution—as likely cause the minimum of such disturbance.

Medical Society of City Hospital Alumni, St. (Mo.).—At the annual meeting of this Society, held De 20, the following officers were elected for the ensuing Norvelle Wallace Sharpe, president; Dr. Francis L. vice-president; Dr. John Green, Jr., secretary, and Dr. W. Soper, treasurer. At a special meeting, held Ja Mr. Charles F. Longfellow, superintendent of public exhibited the plans for the buildings of the new city

Westchester County (N. Y.) Medical Associ members of the Fifth District Branch of the New Medical Association, residing in Westchester Co organization at Portchester, January 22. The called to order by Dr. Frederick Holme Wiggin, City, who explained the plan of organization of, and attention to the by-laws of, the state association organization and government of the county associ some remarks on the same subject, by Dr. John A. W York City, president of the state association, and by Syms, president of the New York County Associatio ward F. Brush, Mount Vernon, was elected tem man. The following officers were then elected for year: Dr. Norton J. Sands, Portchester, presiden Lindsay Porteous, Yonkers, vice-president, and Dr. D MacPhail, Purdy Station, secretary and treasurer. F. Brush, Mount Vernon, was elected Fellow of the sociation as delegate to The American Medical As and Dr. H. Eugene Smith, Mount Vernon, alternate fe delegate.

PHILADELPHIA ACADEMY OF SURGERY.

Meeting held January 7.

Wounds of Venous Sinuses of the Brain.

Dr. Henry R. Wharton delivered the annual address, on thi subject, based on examinations of 70 cases; his personal experiences had been limited to 5 cases.

He cited the case of a boy 12 years old, who had been struck on the occipital bone, a depressed fracture resulting without any marked immediate symptoms, though they appeared the following day, justifying an operation, which revealed that the sinus in this region had been injured, as profuse hemorrhage occurred. Death subsequently followed.

In a second patient, 22 years of age, who had sustained a depressed fracture of the occipital bone, this was elevated, terminating in recovery.

Another case was caused by a compound depressed fracture of the right parietal bone, and at the operation very profuse hemorrhage occurred; recovery followed.

A fourth patient had sustained a fall, striking on the head, but without any immediate symptoms, as he was afterward able to get up and walk into the house. Next day symptoms of compression appeared and he became partially paralyzed on the left side. On the right parietal bone was found a hematoma, and at the time it was not believed that a fracture of the bone had occurred. An operation was done, the hemorrhage controlled by gauze packing, and the patient recovered.

A male of 18 years, who had been struck on the head by a bucket, afforded the fifth case. He sustained a depressed fracture of the right parietal bone, and on removing the fragments of bone there was severe hemorrhage, controlled by gauze packing; recovery followed.

Summarizing the results obtained in the treatment, as shown by the literature on the subject, it might be said that wounds of the venous sinuses of the brain are of infrequent occurrence on account of the protection afforded. In the 70 cases recorded the superior longitudinal sinus was most frequently injured, the lateral next, then the straight, and lastly the cavernous sinus. Of the 70 recovery occurred in 25 per cent. In some instances hemorrhage resulting from the injury of these sinuses was beneficial, as pressure symptoms might be thus prevented. Wounds of these sinuses generally result from direct violence, as gunshot wounds, injuries during childbirth, etc. Some of the older writers did not regard the prognosis as dangerous. Intracranial hemorrhage was present in 26 per cent. of the above 70 cases. If hemorrhage does not occur it may give rise to a blood clot, causing compression. Air embolism was the cause of death following an operation in two instances. A thrombus may occur at the site of injury.

The symptoms of wounds in these sinuses are not always prominent. Those present were generally found to be due to pressure or were symptoms resembling those of apoplexy. If the pia be torn the blood will accumulate under the dura mater. Unconsciousness is not generally present.

As to the diagnosis, sometimes the character of the blood may determine it, especially when attended by injury in the region of one of the sinuses and when attended by symptoms of compression.

The treatment varies. In depressed fractures trephining should be done and the bone removed. To control hemorrhage different methods have been tried. The best is by gauze packing. Others have used the lateral suture method, some the ligature and Dr. W. J. Taylor once applied hemostatic forceps, controlling the hemorrhage. The gauze may contain iodoform or simply be sterilized. The strips should be about two inches in width and should remain in position from three to six days. The very greatest care should be used to prevent sepsis.

Dr. O. H. Allis stated that the diagnosis is uncertain. In some cases he had seen prominent symptoms had not been present. In one of severe injury of the head he had at the autopsy noticed thousands of minute hemorrhages. In injuries of the head he considers it best to shave the entire head so the parts can be better examined.

Dr. W. G. Porter reported seeing one case of wound of the longitudinal sinus resulting from a puncture of a hay-rake, and had been astonished at the amount of gauze that could be inserted without causing pressure symptoms in sinus injuries.

Dr. R. H. Harte had been convinced that these wounds were rare, but in these he would not include such injuries as a severe crush of the skull, as in railroad injuries. In 20 cases of fracture of the skull, which he had seen within the past three months, there had been no wound of the sinuses, and of 114 of fracture of bones of the skull there had been but 1, and that a pin-point puncture. As to suturing large veins, he believes it often saves life, and in one instance he sutured a wound of the jugular vein with success.

Dr. W. L. Rodman had been surprised at the infrequency of wounds of the sinuses of the brain, since fractures in this region are so common. He had only seen 2 such cases. He believes that pyemia is a frequent cause of death in these injuries, and urged early operation. For controlling hemorrhage he considered gauze packing the best, but he had in one instance used the lateral ligature.

Dr. Thomas R. Neilson had seen 3 cases of injuries of the venous sinuses of the brain, 2 of the lateral and 1 of the inferior longitudinal sinus. He had used the gauze packing.

Dr. W. J. Taylor had seen two of the patients reported by Dr. Wharton. In one, when one of the small spicules of bone was removed there was a sudden gush of blood. He believes that a sudden loss of blood from the brain is a more serious matter than the same amount of blood from some other portion of the body.

Dr. R. G. Leconte did not understand why hemorrhage from the vein in this region should be so fatal. If it were arterial blood, then it might be a different matter.

Dr. G. G. Davis thought that probably injuries of the sinuses of the brain occur more frequently than one might think, as reported by the previous speakers. As to hemorrhage in head injuries, it might easily occur from the middle meningeal artery. In other cases it might be from the pia mater, giving rise to subdural hemorrhage, and either might cause pressure symptoms. In one instance he had treated what he believed to be a wound of the cavernous sinus resulting from a fall, the patient striking on the frontal bone. The wound was packed with gauze and the man recovered.

Dr. de Forest Willard had seen 3 cases of wounds of the venous sinuses of the brain, 2 of which were injuries of the superior longitudinal, and 1 of the lateral sinus. He is inclined to the belief that hemorrhage from the brain is not such a very serious matter.

PHILADELPHIA PATHOLOGICAL SOCIETY.

Meeting held January 10.

President, Dr. F. A. Packard, in the chair.

Dr. Joseph McFarland presented a specimen of "Epithelioma of the Mouth and Skin of a White Catfish," also a "Case of Thrombosis of all Four Chambers of the Heart."

Hourglass Contraction of Stomach.

Dr. Ida Richardson and J. D. Steele exhibited an hourglass contraction of the stomach.

Dr. Joseph McFarland stated that he had seen two cases of this condition, usually considered to be of congenital origin.

Dr. F. A. Packard had also seen a similar case to that presented, also undoubtedly of congenital origin.

Dr. David Riesman thought that, as the stomach is simply a tube formed from the hypoblastic tissue, an examination of the tissues might tell whether it had the characteristics of the bowel, or whether the glandular structures of the normal stomach were present.

Dr. Steele said that most writers are of the opinion that such conditions arise from a scar causing contraction.

Nerve-Fibers in the Pia and Cord Regeneration.

Drs. F. X. Dercum and William G. Spiller read a paper on this subject. Dr. Spiller said that the existence of medullated nerve-fibers in the spinal cord is a very rare condition. In the instance reported they had been found in the pia. There had been no degeneration in the posterior roots, and the columns of Goll had been only slightly degenerated. From the existence of many nuclei along the outer layers the sheath of Schwann might also have been present. In this case there had been no evidences of restoration of function in the spinal cord.

Dr. D. J. McCarthy stated that in a case of adiposa dolorosa examined there had been no regeneration in the cord.

Aspergillus in Urine.

Dr. L. Napoleon, Boston, read a paper entitled "Cultivation of the Aspergillus in Urine." At the Philadelphia Hospital he had frequently met with this micro-organism, and had cultivated it on diabetic urine. Aspergillus grown on urine had never produced an alkaline reaction, but on sterile acid diabetic urine it had become alkaline on the sixth day.

Diagnosis of Rabies.

Drs. M. P. Ravenel and D. J. McCarthy read a paper entitled "The Rapid Diagnosis of Rabies," a continuation of the communication presented last June. Formerly, in making a diagnosis of this condition, from two to four weeks were required. His method of preparing the specimens is to fix the tissues in 10 per cent. formalin, and afterward harden them in absolute alcohol for twelve hours, then carrying them through chloroform, imbedded in paraffin and stained with Weigert's methylene blue, or with eosin and hematoxylin. He has examined 28 cases of rabies occurring in dogs, horses and other lower animals, and in 19 out of 21 he has been able to find the rabid tubercle as well as the chromatolysis heretofore described.

At the Philadelphia Hospital he had frequently met with this micro-organism, and had cultivated it on diabetic urine. Aspergillus grown on urine had never produced an alkaline reaction, but on sterile acid diabetic urine it had become alkaline on the sixth day.

Diagnosis of Rabies.

Drs. M. P. Ravenel and D. J. McCarthy read a paper entitled "The Rapid Diagnosis of Rabies," a continuation of the communication presented last June. Formerly, in making a diagnosis of this condition, from two to four weeks were required. His method of preparing the specimens is to fix the tissues in 10 per cent. formalin, and afterward harden them in absolute alcohol for twelve hours, then carrying them through chloroform, imbedded in paraffin and stained with Weigert's methylene blue, or with eosin and hematoxylin. He has examined 28 cases of rabies occurring in dogs, horses and other lower animals, and in 19 out of 21 he has been able to find the rabid tubercle as well as the chromatolysis heretofore described.

The speaker detailed a case of a girl 8 years of age, who had been bitten on the ear by a dog supposed to be mad, six weeks previous to the onset of the symptoms. The wound had been cauterized by nitrate of silver and had healed promptly. On the appearance of the first manifestations the child complained of distress when her face was cleansed with a dampened towel. On attempting to swallow water, spasm of the muscles of the throat occurred. Later, fever developed, as did convulsive seizures, some of which were followed by periods of unconsciousness, and finally death. At the autopsy minute hemorrhages of the brain were found, and some of the material inoculated into rabbits and carried through four generations produced the disease. Cultures were repeatedly made but always remained sterile, proving that the micro-organism of this disease is different from that of any other type.

Dr. F. Krauss detailed the clinical history of this case. The child had never been informed that the bite of the dog had anything to do with her disease. The spasm of her throat was most intense, and the temperature ranged from 100 to 103. The condition conformed in all its symptoms to those detailed by Osler.

Bronchial Cyst.

Dr. W. M. L. Coplin reported a case of this condition in a patient of 36 years. It was operated on by Dr. W. W. Keen. Beginning three years ago, within eight months it had grown as large as an almond, and subsequently becoming painful the operation was decided on. The cyst was lined by epithelium resembling that of the pharyngeal mucosa and tonsils.

Infarcts from Enterocolitis.

Dr. William Pepper presented specimens of the liver, kidneys and spleen from a case of enterocolitis occurring in a child of three months of age. The liver showed a marked degree of fatty degeneration, and the kidneys exhibited a large number of hemorrhagic infarcts.

DENVER AND ARAPAHOE MEDICAL SOCIETY.

Regular Meeting held January 22.

Aneurysm of Innominate and Aorta. Insertion of Silver Wire. Recovery.

Dr. Leonard Freeman exhibited a patient who suffered from aneurysm of the innominate artery with involvement of the arch of the aorta. When the patient came under Dr. Freeman's observation, the right clavicle was dislocated from pressure of the aneurysm, the sternum was eroded, there was dyspnea due to pressure on the trachea, eye symptoms were present and aphonia. The administration of potassium iodid and the injection of gelatin were tried without effect. The aneurysm increased in size and all the symptoms became aggravated. In August, 1900, five feet of silver wire was introduced on an insulated needle, the negative pole of battery attached and 75 milliamperes of electricity used for half an hour. The needle was then removed. The improvement was slow, but steady. Only a slight heaving remains and the tumor is imperceptible. All the symptoms improved correspondingly. The voice returned; no dyspnea. Dr. Freeman reported a similar case in a man of 50 years of age. There was profuse hemorrhage on introducing the needle, which was checked as soon as the electric current was turned on.

Dr. John S. Miller in discussing the subject said that therapeutics has contributed very little to the cure of aneurysm, and we still look to surgery for its relief. Several years ago he ligated the common carotid and subclavian arteries for aneurysm of the innominate artery involving the arch of the aorta. The patient improved considerably, but died sixty days later, from rupture of the sac. The needle should be short, to facilitate the easy and prompt introduction of the wire. It should be directed away from the heart, so that the wire or its kinks may not enter the semilunar valves. If fifteen to twenty feet of wire can be introduced, it is all the better. He suggested that while the current is on the common carotid artery be compressed with a view to preventing the migration of any coagulum that might possibly become detached from the wire during its introduction.

Symposium on Recent Epidemic of Influenza.

Dr. W. C. Mitchell, in speaking of the bacteriology of influenza, dwelt on the importance of making bacteriologic examinations by which the advent of an epidemic may be predicted with certainty and the proper prophylactic measures adopted. He remarked that the bacteriologists of the Chicago Board of Health predicted an epidemic of influenza as early as November last, and then mentioned the tenacity with which the bacteria of Pfeiffer hold to the patient. He found the bacteria in 1898 in a patient who had influenza in 1895.

Dr. W. N. Beyzs, in speaking of the pathology of influenza, dwelt on the fact that in sporadic cases the mortality is greater than in epidemic cases.

Dr. G. E. Tyler believes in the contagiousness of the disease. The first case occurring in a family should be isolated, and the discharges disinfected. Sudden chilling and public assemblies should be avoided during epidemic.

Dr. C. B. Van Zant had observed, during the recent epidemic, cases simulating appendicitis and peritonitis. In one the rectum was involved and he noticed swelling of the lymphatic glands, while in another there was dysphagia out of proportion to slight involvement of the pharynx.

Dr. A. Zederbaum considered the recent epidemic as mild compared with that of 1889. He had observed a tendency to ear complications, and two cases in the same family were complicated with mastoiditis, and in one both mastoids had to be drained. His youngest patient was 9 months old, and the oldest 78 years.

Dr. C. D. Spivak had noticed a peculiar yellowish hue of the sclera in almost all of his patients, and in one the jaundice was universal. He mentioned the extraordinary loss of weight in all cases, and reported a case which during convalescence developed grave gastrointestinal sequelæ.

Dr. H. B. Whitney had administered 10 grains of quinin daily to all his patients. For the headache he gave phenacetin and caffein every hour, and codein for the pain; also strychnin freely. He has had but two complications in over one hundred treated.

Dr. William H. Bergtold said he had never used quinin. He considers the administration of a coal-tar preparation with salicylic acid almost specific, and prescribes phenacetin with salophen. The dose of salophen should be from 25 to 45 grains. He believes we will have, in the near future, an antitoxin serum for influenza. In the infectious types of influenza he uses Credé's ointment.

Dr. J. W. Hall dwelt on the uncertainty of prognosis in influenza complicated with pneumonia.

Dr. J. T. Eskridge divided the nervous symptoms into those occurring at the onset of the disease, accompanying it, and the sequelæ. He considers the nervous phenomena as a disease, not symptom. In one patient the disease was ushered in with delirium and death followed the next day. In another, optic neuritis developed early. Neurasthenia is a frequent sequela.

Dr. B. Oettinger reported a case of influenza complicated by abscess in the antrum.

Dr. R. Levy corroborated the statement of Dr. Zederbaum with reference to the prevailing complication of ear troubles.

Dr. M. Black had several cases of middle ear complication and advises early puncture of the drum. He used leeching with considerable advantage.

Dr. T. J. Gallagher decried the use of the nasal douches which give directions to hold the head backward and to close one nostril, for the use of this douche has caused many middle-ear inflammations.

DETROIT MEDICAL SOCIETY.

Meeting held Jan. 16.

Surgery of Purulent Otitis Media.

Dr. Emil Amberg gave a short sketch on this topic, with a demonstration of prepared specimens. He said that a paracentesis, as such, is practically harmless, and that danger accompanies only a delay. The curative value of the incision and the prophylactic were considered. An early paracentesis is especially indicated in otitis after influenza. The necessity of timely removal of a polypus is obvious. Diseased ossicles should be removed in order to get rid of a focus of infection, and also to make the epitympanic space more accessible to treatment. He pointed out that we frequently find general practitioners, and quite a number of oculists, speaking with a feeling composed of fear, impatience and disgust of the treatment of diseases of the ear. The teaching on ear diseases in general seems not to be carried out with the necessary thoroughness, and it is to be regretted that the combination, oculist and aurist, is still upheld in many parts of the country. We should prefer to be without the expression, "the personal equation of the surgeon." This term is intended to excuse the non-interference in cases requiring interference, if the physician is unable to take a hand. Nothing is more dangerous than an excuse based on hypothetic and unscientific reasons under so plain and simple circumstances. He described the various operations and showed a large number of prepared specimens illustrating the anatomy of the ear, the mastoid and the radical operation.

Non-Operative Treatment of Ear.

DR. EUGENE V. RIKER also read a paper, saying: One of the first things demanded of the physician by a person suffering from acute inflammation of the middle ear is relief from pain. If seen at the commencement, the patient should be put to bed, a saline cathartic administered, and dry heat applied. Avoid all kinds of oils, aqueous solutions and moist heat. Some recommend solutions of cocain, atrophin, and morphin, alone or in combination, but I cannot see how they can be absorbed when the drum is intact, for I have never been able to render a non-perforated drum insensible, even when there was marked inflammation present, by the use of the strongest solution of cocain. If the alkaloids are not absorbed the relief, if any, is due to the heat, which is far better supplied dry, for when water is poured into the ear and allowed to run out immediately, some is sure to remain in a depression in front of the drum and thus act as a poultice, which would favor the breaking down of tissue in rupture of the drum. Opium, in my mind, should seldom be used, for it is not possible at the outset to tell the nature of the infection, and in case of mastoid involvement it might mask the symptoms until it was too late for successful operative interference.

Current Medical Literature.

AMERICAN.

1. **Mammary Tumors.**—The special point of Shrady's paper is the importance of the early diagnosis of malignant diseases of the breast. All cases of breast tumors should be suspected. No growths in this region can be trusted. Fully 90 per cent. of breast tumors in older women are malignant, and the remaining 10 per cent. very objectionable. The safe side, then, is the removal of all growths, whether in the young or in the old.

2. See abstract in THE JOURNAL of February 2, p. 343.

3. **Gout.**—Haig details his well-known theories as to the causation of gout. He thinks it is due to poisoning by flesh, tea, etc., or some substances which introduce uric acid into the body in large quantities, where it may remain and also prevent the excretion of the naturally formed uric acid. In this saturated condition the fibrous tssues may be irritated, producing gout or rheumatism; the capillaries may be disturbed, causing a group of circulation diseases, uric acid headache, epilepsy, insanity, anemia, Bright's disease, etc. All the diseases produced by uric acid fall into these two groups, the local and circulation groups, of which the latter is far more extensive. The indications for treatment are to cut off the poisons so that the introduction shall cease, and to provide for elimination. He thinks that altering the diet alone sometimes produces improvement, but the main point is to get substances which increase the solubility of uric acid in the blood. The action of the salicylates in the circulation are given, cases pointed out and the dietetic rules which should tend to improvement of the conditions.

4. **Nasal Polypi.**—Wright argues that the so-called nasal polypi are not myxomatous, as so commonly held, but simply edematous infiltrations, and that the recognition of this fact is a necessary preliminary to understanding the non-nasal morbid processes.

6. **Surgery of the Stomach.**—Bouffleur's paper is a review of the conditions of the stomach requiring operation and the measures that have been devised for their relief.

7. **Ligature of the Innominate.**—Delaup reports another case of ligature of the innominate artery for high innominate, carotid and subclavian aneurysm, followed by simultaneous double ligature of the common carotid and vertebral arteries at a subsequent operation. Death occurred after the second operation, from exhaustion, twenty-one days after the first. The

author reviews the literature and gives a tabulated list of cases. Of the four successful ones, only one approached being a complete cure, and the patient died from hemorrhage from aneurysm ten years after the operation. He thinks that in the future, with modern aseptic methods, a better record will be made, as the operation is justifiable and advisable under certain circumstances.

8. See abstract on p 402.

9. **Gonorrhea.**—Cabot's plan of treating gonorrhea with argonin is to begin within twelve or thirty-six hours after the first signs of anterior urethritis with no old deep trouble. He first takes a specimen of the discharge for microscopic examination, then the patient passes urine, after which the urethra is washed out with hot water. Then twice a day a 10 per cent. solution of argonin, freshly made, is introduced by Ultzman's deep injection syringe, or better still, by a rubber bulb holding about 6 drams. The bulb should have a rubber tip about two inches long, and be such as are sold under the name of ulcer syringes. The solution is introduced hot, and kept in the front urethra by pressing the lips of the meatus together as the point of the bulb is withdrawn. Then an application of 10 per cent. argonin solution is made with an applicator tightly wrapped with absorbent cotton introduced into the urethra, while the solution previously introduced is allowed to gradually flow out. The cotton swab should be gently applied to all parts of the anterior urethra for two to three inches, and then withdrawn. The solution remaining in the urethra is then allowed to escape and the operation repeated, not using the applicator if the patient suffers much from it. In some cases gentle kneading of the urethra while the solution is in place is advantageous. Everything must be done gently and slowly, and the solution be kept in for five or ten minutes. Cabot disapproves of the use of cocain, as it interferes with the patient's testimony as to his sensations, thus gauging the conditions. The first two or three treatments will usually show how the case is going to turn out. If all is going well, the disease remains stationary for two or three days and then gradually subsides. Internally, citrate of potash may be given to render the urine bland. The patient is directed to soak the penis in hot water three times daily, and the general condition of his health, the use of alcoholics, etc., restricted, and he should be kept as quiet as possible. If the progress is favorable, the strength of the solution is gradually increased up to as much as 30 per cent., and after several days, if he is still doing well, an astringent injection of lead acetate, tannic acid, zinc sulphate, copper sulphate—of each 2 grains, in tablets—in from four to eight ounces of water, is to be used by the patient after each urination. The argonin treatment is additional and must be given by the physicians. He says, in conclusion, that this method of treating incipient gonorrhea is safe, and all his cases have been satisfactory so far as traced, and have shown permanent results, there being no return later from deep lesions. The solution must be freshly prepared each time, and must be used hot, at a temperature of 110 to 120. There is no use in attempting to make a rapid cure this way unless the patient is prepared to implicitly follow the physician's directions in all particulars.

10. **Shortening After Coxitis.**—Taylor has studied the shortening occurring after hip-joint disease, and reaches, rather against his pre-conceptions, the following conclusions: 1. Considerable retardation of growth both in length and thickness of the limbs is the rule after coxitis and other affections causing long periods of lameness or disability in childhood. 2. The amount of retardation appears to bear a distinct relation to the amount and duration of retardation or disability. 3. This inhibitory effect of restraint should be considered in selecting the treatment. Other things being equal, locomotion is desirable and restraint for long periods harmful, though it may be necessary as the least of two evils.

11. See abstracts on pp. 401, 402.

12. **Gastro-Enterostomy by the Elastic Ligature.**—This method is by the application of the elastic ligature binding the viscera together and ultimately cutting its way through. The special technique, as given by McGraw, is as follows: 1. The ligature should not be a rubber thread or flat band which lacks the necessary strength to cut a way with certainty through the thick walls of the stomach. The surgeon must use a hard, firm rubber cord at least 2 millimeters in diameter. 2. It must include in one loop all the tissue that it is desirable to sever. The formation of several small connected loops is an error. The larger the amount of tissue included in the loop, the more securely and more certainly will the ligature perform its work. The cord must be drawn as firmly as possible, and be fastened by a silk thread tied around the ends. He has himself first knotted the rubber cord and then fastened it with silk. This first procedure may not be necessary. 3. Before inserting the rubber ligature the viscera should be joined together by a row of Lembert sutures for a distance of six or seven centimeters, and when the ligature has been tied a similar row in front should complete the procedure. The author thinks that if the method should ever fail it would be from its too rapid action. He believes that this method is unequaled in the rapidity of its action, its efficiency and its safety, and reports a few cases in which he performed gastro-enterostomy for carcinoma of the pylorus by this method, and one case in which it was performed for the production of a fistula between the gall-bladder and the small intestine. He does not think that it is best for this latter purpose, owing to the thinness of the gall-bladder walls, but for gastro-enterostomy it is the best adapted operation. The matter was made the subject of his address as chairman of the Section on Surgery and Anatomy, before the American Medical Association in 1891, and published in The Journal of May 16, that year.

13. **Infant Feeding.**—Rotch concludes from experiments made by Drs. White and Ladd, under his supervision, that the addition of cereals to cow's milk for young infants is unnecessary, because better results can be obtained by other methods, and it is irrational since it differs from Nature's methods. In a certain proportion of cases where the cream is mixed with milk, water and lime-water, the emulsion at times appears partly disturbed, and this condition has been held by some to counterindicate the general principle of the percentage feeding. This subject has also been investigated and he does not find that the disturbance of emulsion does any special harm. As regards the management of proteids in infant food, he says that an object to be kept in view in regulating the lactation of the first twelve months of life is, in the early months, to start with a low percentage of proteids and to make the composition of this low proteid in the proportion of two-thirds whey and one-third caseinogen. As the infant grows older we should not only increase the proteids so that in the latter part of the year it can take the high total proteids of undiluted cow's milk, but also that the proportion of whey proteid to caseinogen should, as the total proteid becomes higher, be gradually changed from two-thirds whey to the one-sixth contained in the total proteid of cow's milk. He gives a table of prescriptions that it is possible to follow in the milk laboratory, and he believes that it is perfectly possible with the good milk supply, such as comes from the laboratory farm, to prescribe a percentage mixture which will retain its emulsion except under extraordinary circumstances of transit and heat. It need not be Pasteurized excepting for long distances in hot weather, and will not need to have cereals added for their mechanical action. He thinks that a centrifugal cream no more disturbs an emulsion than a gravity cream, and therefore is preferable as about one-half a day fresher.

14. **Bacteremia and Indications for Hysterectomy.**—Boldt objects to the ordinary terms septicemia and pyemia, and after discussing the definitions given by various authorities, suggests the following: Septicemia—or acute bacteremia—is a blood disease caused by parasitic micro-organisms invading the circulatory system or some primary seat of infection. Usually the infection multiplies so rapidly in the blood as to usually carry the patient off in about five days. The germ is usually staphylococcus pyogenes, but other forms may also occur. Pyemia—chronic bacteremia—is an infection of the system by streptococcus pyogenes, alone or with other pathogenic germ

beginning from an infected thrombus. They are not diffused into the system in one large quantity, nor do they possess the same extreme virulence as in the acute type from a clinical point of view. The production of the abscesses found in the condition called pyemia, on which depends the pathologic differences between the acute and chronic, is due to the organism finding a resting place outside the circulation and there giving rise to abscess. He would therefore call septicemia, acute bacteremia; and pyemia, chronic bacteremia. In the second part of his paper he discusses the indications for hysterectomy, and sums them up as follows: If, after a full-term delivery or an abortion, there are no conception products in the uterus, and the patient has fever with exacerbations, chills, and a small and frequent pulse—120 to 140 or more—if careful observation should show that the infection comes *from the uterus alone*, that organ being enlarged, and relaxed in its consistency, if there is no evidence of peritonitis, the parametria being free, if streptococci are found in the uterus, and, especially, if the blood shows the presence of pathogenic germs, as in Prochownick's patients; if there are decomposition products in the uterus, as in the instances reported by Schultze, Sippel, Prochownick, Stahl, and others, which can not be removed satisfactorily *per vaginam;* if, on doing a Cesarean section, the uterus is found septic, then an abdominal hysterectomy is indicated. Abdominal section with drainage is indicated in diffuse septic peritonitis when there is no evidence of an exudate in the pelvis. The annexa are to be left undisturbed unless there is some positive indication to do otherwise.

15. **Blood Poisoning.**—Harvey calls attention to the effect of arsenic in large doses, and the difference when given in small quantities, the susceptibility of some persons to mercury, bromids, iodids, and the dangers from the prolonged use of full doses of strychnin or quinin.

16.—See abstract in The Journal of February 2, p. 343.

18. **Babinski Reflex.**—According to Prince, there appear to be two reflexes comprised under this head, one spinal and the other cerebral, the latter being an extension movement which he considers automatic, as in dodging the head before an expected blow. They may be inhibited largely through the will, though not always. With proper precautions to inhibit cerebral reflexes, extension of the great toe never occurs in health. Extension of some of the other toes may occur, but in some of these cases, at least, it is also a cerebral reflex. The significance, then, of the Babinski phenomenon consists in extension of the great toe, and he thinks the best term for it would be "the great toe phenomenon," (like knee-jerk, etc.) It does not follow, however, that extension of other toes may not be of pathologic importance. He has observed them in certain cases, such as meningeal hemorrhage, and in some obscure ones of cerebral disease. He thinks this recognition of the cerebral element is of practical importance in interpreting the pathologic signification of extension.

20. **Vesical Implantation.**—The case reported by Reynolds is explained in detail. He thinks that the Dudley operation entirely obliterates the danger of slipping away of the ureter from the bladder, and the presence of forceps must at the same time direct the stream of urine into the bladder; in this case it produced no discomfort. The result was remarkably successful. Aside from the high position of the new urethral opening it could hardly be distinguished from the corresponding one on the unoperated side.

21. **Pregnancy After Ovariotomy.**—The case reported by Morris seems to have been one of complete removal of the ovaries and tubes, and yet pregnancy followed. It is suggested that there must have been a supernumerary ovary in this case, and possibly another ostium between the uterus and the ligature of the tubes.

22. **Lakewood (N. J.) as a Winter Resort.**—Schauffler finds that the advantages of Lakewood are due to two factors: 1. The comparative mildness of the temperature and its phenomenal dryness. He thinks it specially beneficial for asthma, bronchitis, laryngitis, and also in the first stages of tuberculosis. It is also a good locality for convalescents from acute diseases. The soil, location, etc., are, he thinks, particularly good for a northern climate. The average humidity is low and there is no appreciable moisture in the air for any considerable portion of the time.

23. **Climatic Treatment of Bright's Disease.**—The authors find the highest mortality from Bright's disease is in the middle Atlantic Coast region, the next the North Atlantic, next the northeastern hills and plateaus, the South Atlantic Coast region, and, lastly and least, in the Southern Central region. A part of this prevalence in some of these regions is due to other than climatic conditions, urban concentration, etc. The most unfavorable states to those suffering from renal diseases are New Jersey, New York, Massachusetts, New Hampshire and Vermont, and those most favorable are Tennessee, Georgia, Nebraska, North Carolina, Arkansas, Texas, and certain parts of southern California.

24. **Syphilis at Hot Springs.**—Jelks finds the climatic and social conditions of Hot Springs, especially advantageous to cases of this disease. The advantages are regulation of diet and living, such as favor treatment, the unequalled bathing facilities, drinking of hot water favoring elimination, while the drug treatment may be carried to a much greater extent than in other sections.

25. **Florida.**—After describing the climate, geography, etc., of Florida, Crook gives the following as the classes of cases best suited to be sent to that region: 1. Cases of recurring bronchitis or winter cough. 2. A large and important class of cases, hereditary or otherwise, in which there is reason to fear the development of tuberculosis, though there may be no signs of the disease. 3. The majority of cases of early phthisis prior to cavitation. Patients showing great debility or severe anemia should not be sent to a southern climate, nor those in whom acute manifestations are present. As in other localities, cases where the symptoms are prominent are not welcome everywhere, but he knows of no case where comfortable quarters could not be obtained. 4. Cases of so-called fibrous phthisis or chronic interstitial pneumonia are always benefited. 5. A large class of invalids, rheumatics, victims of subacute or chronic gout, asthmatics, intractable cases of chronic rhinitis, pharyngitis, laryngitis, lumbago, general debility, etc., are usually improved by a season in Florida.

26. **Climatology of Neurasthenia.**—Two extremes should be avoided by neurasthenics, a low, windy, treeless climate, and a high altitude, above 2,000 feet, with quiet atmosphere and low atmospheric pressure. As an illustration of the former condition he mentions Portland, Ore.; of the latter, the higher parts of southern California and New Mexico. Aside from idiosyncrasy, he says the ideal condition consists in sea air in a well-wooded country far enough from the coast to avoid its fogs; a sea voyage is an excellent preliminary to other measures. An altitude of over 2,000 feet, a very stimulating climate, districts visited by high winds and frequent fogs, cloudy saturated atmosphere, with slight movements of the air-currents, a low warm sea-level country, etc., should be avoided.

27.—See abstract in The Journal, xxxv, p. 1171.

28. **Heart Disease in Children.**—Friedlander first notices the relations of the heart to the chest wall in children as compared with adults, and the position of the apex; the area of absolute dulness is somewhat larger. In this paper he follows much the same general line of reasoning as given in Poynter's article abstracted in last week's Journal, p. 351, describing the symptoms of endocarditis, pericarditis, and myocarditis as they occur in infants and children.

29. **Resinol Dermatitis.**—Reynolds defends resinol against the attack made on it by Heidingsfeld's paper, in The Journal of January 12, p. 137. He thinks that it is a valuable remedy, and if anything is to be called a specific it is, not only in the surgical use, but in a far more important group of diseases, those of the gastro-intestinal tract, particularly typhoid fever.

35. **Spinal Curvature.**—This paper consists in an analysis of 500 cases, mostly hospital patients, and the great majority

of them females. The chief causes seem to have been heredity, rachitis, general weakness, bad posture and habits. The most common form was right dorsal and left lumbar convex, over 50 per cent. of the total being of this type. The patients were treated by attention to the general condition, the use of hypophosphites, cod-liver oil, bland iron preparations, straightening of the spinal column by manual pressure, mechanical pressure and various splints such as Barwell's orthopedic apparatus and Volkman's sloping seat, keeping up the improved position by means of a special apparatus devised by the late E. T. Chance, which consists of a metallic splint between the shoulders, having attached to it two straps which pass through the axillæ, bracing back the shoulders, joined to a perpendicular slotted rod which passes downward to a crescent-shaped metal band—pelvic girdle—joined in front by a strap and situated on a level of the crest of the ilium and great trochanter; over the convexity of each curve a plate is accurately adjusted by means of short metal arms which connect the plates to the perpendicular rod. A broad abdominal belt completes the splint. All parts touching the skin are padded and the adjustment is made by wrenches and keys. The splint must be fitted perfectly at the first adjustment, and be altered as improvement progresses, so as to keep up a better position. The patient should be directed to "keep away from the plates," as every time this is done and better position is gained she can not resume the more faulty position. In addition special exercise for weakened muscles—massage, galvanization, etc.—is employed.

38. **Nephritis in Children.**—While drug nephritides are not uncommon in children, the specially important types of the disease are those which follow or accompany acute infectious disorders, scarlet fever, diphtheria, etc. The most dangerous types, of the trouble of this sort, which Gradwohl has seen, are those which occur in scarlet fever where the symptoms of the disease itself are almost *nil*. He calls attention to the necessity of making urine analysis of children's urine passed in the whole twenty-four hours, and calls attention to the fact that the amount of albumin present has nothing to do proportionately with the amount of edema. Hemorrhagic nephritis complicating scarlatina has a better prognosis than those acute types accompanied with pale urine and not much albumin—glomerulonephritis acuta. In diphtheria this complication is even more common than in scarlatina, but we seldom see hemorrhagic nephritis with this disease or edema or uremia. It is rare after measles, sometimes occurs with a hacking cough or nephritis, and may occur after gastro-intestinal disorders and eczema. There is also a nephritis of anemic children in which it is well to examine the urine. The peculiar form is the type that comes and goes, disappearing when the child goes to bed and returning when it gets up and goes about again. Although it is rare that chronic nephritis is seen in children, it occasionally follows the scarlatinal type.

40.—See abstract in THE JOURNAL, xxxv, p. 1050.

45. **Cutaneous Epitheliomas.**—Pusey reports cases of cutaneous epithelioma treated by caustics, with good success in all eleven. He calls attention to the fact that epithelioma of the skin, especially the superficial type, is often slow in progress and has little tendency to metastasis. The cases usually come to the dermatologist in the early stages, hence the favorable results. His method was to first curette and then use a caustic, pyrogallic acid; in all cases working under cocain. He thinks, however, that pyrogallic acid is less safe than a caustic, which more surely destroys diseased tissue. He has lately used the saturated solution of chlorid of zinc with most satisfactory results. This method of curetting and the use of caustics acts better than the knife, as it is not necessary to cut out into the healthy tissue. The cosmetic effect is also better.

47.—See abstract in THE JOURNAL, xxxiv, p. 51.

48. **Malaria.**—Well's article is a brief but thorough statement of the present state of our knowledge in regard to malaria.

49. **Pernicious Malaria.**—The casual factors, the estivo-autumnal parasite, the pathogenesis of pernicious symptoms, the secondary elements in the determination of perniciousness, the symptomatology in detail, the diagnosis and differentiation of the pernicious type of malarial fever are described by Edwards. He recognizes the occurrence of occasional rare instances of the pernicious type from the ordinary tertian parasite, though in most cases it is due to the estivo-autumnal species; it forms, however, only a small proportion of the cases thus caused.

50. **Crescent Form of Malarial Parasite.**—Preble has formerly expressed the opinion that the crescent form of malaria did not occur in Chicago, but has since learned of a few cases. He describes the crescent parasite and mentions their diagnostic significance. They are not always readily found, and sometimes repeated examinations are required. In a few cases he has been able to find them after a small dose of quinin, when the blood had been repeatedly examined before without their detection. As long as they are found the patient is in danger to others and should be carefully protected against mosquitoes for fear of contagion.

51. **Treatment of Malaria.**—The first point insisted on by Favill is a positive diagnosis before any treatment is attempted. The fact that other diseases recover under quinin, besides malaria, adds another possibility of misinterpretation. Assuming that we have made a correct diagnosis to determine the type, the treatment is comparatively simple with the ordinary forms; with the estivo-autumnal fevers, however, we have many difficulties. They are very baffling and irregular in their course, but there is no doubt that quinin is also a direct antagonist to these as to other types. What we are to do with these cases that do not yield, is difficult to say. The authorities state that 15 to 30 gr. a day is sufficient for any case of malaria, but we know that there are many where it is not effective and others where it would be too much, and the question arises whether or not we should be heroic in the use of the remedy. Some practitioners say that enormous doses of quinin are not absorbed. If we could be sure of this there would be some comfort. There is some reason to suppose that large quantities are absorbed, but yet ineffective. Favill believes that the hypodermic administration of the drug is possible, though there are objections to it. The danger of local necrosis is great, and he thinks that after all there may be some associated or consequent toxemia in these resistant cases that quinin does not touch. We can not tell, however, whether we are dealing with a continuous infection or the indirect results of infection. Our therapeutists blunder along and we give quinin because we have nothing else to do. What are the terminal aspects of malarial infection? For the most part the lesions are in the nervous system, but when there is a deterioration of blood its rejuvenation becomes an important question in the cases after infection has once been subdued. As regards the administration of quinin, he thinks that much will depend on the characteristics of the case. The question can not be decided off hand. The drug must be administered according to the necessities and possibilities of the case. The point is to get quinin into the blood in sufficient quantities, and this leads to the statement that there is no such a thing as a regular dose of quinin; a dose is that which will produce the desired effect.

52. **Medullary Anesthesia.**—According to Weber, our aim at the present time is to define the scope and limitations of medullary anesthesia. We can use the method in all gynecologic and obstetric operations, all genito-urinary and intra-abdominal and groin operations, such as hernia, bubos, etc.; all operations of scraping, manipulation, etc., of the abdominal wall, and operations on the lower extremities. He advises against its use in children, partly because of the mental effect of the method and because they take anesthesia so easily. In old age, however, it would be of great value, as aged people, as a rule, bear general anesthesia badly. Men bear the method better than women. The psychologic effect is less. In emergency or accident surgery it is of great value, also in military

or country practice. Operations can be done in the office under this method such as operations for bubo, varicocele, etc. For surgical practice amongst the poor it is valuable, and the non-necessity of a skilled assistant makes it an important gain. Patients suffering from emphysema, chronic bronchitis, pulmonary tuberculosis, fat people, old people, alcoholics, those suffering from chronic nephritis, atheromatous arteries, myocarditis are dangerous risks for chloroform or ether and medullary anesthesia will here come most into play. As regards its dangers, he says we will have no deaths if we do not overdose. The direct toxic effects are mentioned as slight. The other possible cause for death is sepsis, and this can be guarded against. There are some disagreeable effects connected with it, such as vomiting, headache, etc., but they are not dangerous.

60.—See abstract on p. 401.

61. **Specific Lesions of Rabies.**—Spiller holds that the so-called specific lesions of rabies are of diagnostic value, but are not absolutely confined to this disease. From his own experience he thinks that many of these lesions are simply due to irritation or intoxication and it is not necessarily rabid.

62. **Experimental Pancreatitis.**—Flexner, in a previous study, found that the secretion of the pancreas may enter the peritoneal cavity without setting up diffuse inflammation, a conclusion previously arrived at by Senn, and in a certain number of instances the free, sterile pancreas or pancreatic secretion may cause local fat-necrosis. The element of infection plays an insignificant if not altogether unessential part. In the peritoneal fat-necrosis the fat-splitting ferment is demonstrable at certain stages of the peritoneal process. It is present in the greatest amount in the early stages, and may disappear later. Although it can not be confirmed that steapsin is the direct cause of necrosis of the tissue, this is rendered highly probable by its constant occurrence in disease areas, its absence from the healthy fat, and the nature of the pathologic changes. The escape of the pancreatic secretion into the peri- and para-pancreatic tissues is the origin of the necrosis, and this escape is facilitated not only by lesions of the pancreas itself but also by obstruction of its circulation. This may be brought about by injuries of the pancreas, and ligation of the ducts, as well as by the production of passive congestion. He has since made, and here reports, a series of experiments by injections of acids, alkalies, bacilli, etc., into the pancreas of dogs with chemical and microscopic examinations. The results reached are that hemorrhage per se is common in all forms of the pancreatitis, but when excessive, dominates the process. It is usually more pronounced than the inflammatory lesions, and the two conditions may be separate and distinct in the same organism or different parts of the organism. The necrosis is due to perversion of pancreatic secretion, and the direct result of the action of the fat-splitting ferment. The hemorrhage does not commonly occur independently of inflammation, and one of the lesions is disintegration of pancreatic tissue. If we recall the tendency of the pancreatic secretion to act with the pancreas, it follows that these injured foci might better become the starting-point of another form of degeneration leading to necrosis of the glands and reactive inflammation; that this dead tissue might also form a favorable point of location and multiplication of micro-organisms whose presence would still further complicate the condition.

63. **Kalagua.**—Kalagua is a Japanese plant transplanted to South America, which has been reported a specific for tuberculosis, and reports have been made by Stubbert and others and certain claims as to its influence recorded. Bergey reports the results of experiments made on guinea-pigs and rabbits, in tabulated form, some of the animals being inoculated with tubercle bacilli, and others not. In none of the experiments was there any positive evidence of a beneficial specific influence of kalagua. If it is really, as claimed, a specific for the disease, it is most probable that some evidence of its action would be apparent in these experiments, but no effect traceable to the drug was observed.

64.—See abstract in The Journal, xxxv, p. 1105.

77.—See abstract in The Journal, xxxiv, p. 1335.

78. **Eye-Strain and Digestive Disorders.**—Benedict's views in regard to the relation of eye-strain to digestive disturbances are rather conservative. He points out that statistics as to the frequency of this relation are not practicable, and that the correction of digestive disorders by glasses is sometimes ineffective, though there is no doubt but that eye-strain in certain conditions may react in pneumogastric reflexes. True pneumogastric reflexes, nausea, etc., are not caused by any sensory disturbance other than those of sight and equilibrium, excepting either change of temperature or psychic translation. He tries to explain the psychic processes by which nausea is thus excited tentatively, the stomach by virtue of its contents and the liver by virtue of its own inertia—and the fact that it is the only body that changes in its inertia can readily be appreciated—are admirably adapted to transmit sensations of equilibrium. Other afferent measures which they transmit to conscious centers must be by the pneumogastric nerve and the overstimulation of the function of a nerve of manifold functions is apt to be associated with sensations apparently representing the nerve in other functions. He is skeptical as to the equilibrium function of the semicircular canals.

79. **Membranous Colitis.**—Robison describes the symptoms and pathology of membranous colitis, which he divides into two classes. 1, those due to enteroptosis, lack of digestive ferment and intestinal calculi. 2, those due to dyspepsia, traumatisms, and grave cachectic diseases, septic and infectious conditions and carcinoma. The prognosis must be guarded, though the mortality is low. The treatment depends on the character of the conditions; enteroptosis, dyspepsia, etc. Only surgery can relieve deformities of the internal viscera. Intestinal antisepsis by free colonic flushing and by the mouth gives relief. The diet should be ample, varied and digestible. In all cases it is well to exclude rich soups, gravies, etc. Hygienic dress, an abdominal bandage, exercise, change of scene, attention to renal insufficiency, flushing of the bowels are all mentioned as of advantage. He has had benefit from a solution of methylene blue, 1 grain per quart by rectal injection given high. Medicinal treatment is confined to intestinal antiseptics, the best of which he thinks are bismuth salicylate, salol, betanaphthol, thymol, benzoic acid, menthol, guaiacol carbonate and creosote. It is necessarily symptomatic and should be varied to suit each individual case.

82. **Hysterical Alopecia of Eyelids.**—Under this name Gifford describes cases in which the eyelashes were pulled out by hysterical girls, thus simulating a diseased condition.

86. **Congenital Pyloric Stenosis.**—Southworth reports a case in a child, which lasted for nine days after birth, and in view of the complete cessation of vomiting at this time, he is inclined to think the condition more functional and spasmodic than otherwise. There was no palpable tumor nor dilatation of the stomach.

87. **Retropharyngeal Abscess.**—Three cases of retropharyngeal abscess in infants are reported by Snow, who discusses the diagnosis of the condition. He thinks the failure to recognize the abscess in babies arises from the hesitancy to hurt the child by digital examination of the throat, and insists on the importance of this measure. The condition is such that everything possible should be done to relieve it. The symptoms are usually misunderstood, and hence may not guide us to a correct conclusion.

89. **Scurvy in Cuba.**—Duenas has not found any cases of scurvy described in Cuban literature since 1889, but reports personal observations of his own. He calls particular attention to the connection of anemia with scurvy, and asks whether we should consider it as a special clinical form of progressive anemia? He thinks that alteration of the blood is the first pathogenic link of all manifestations to follow. Further observation would be required to establish the relations of scurvy with progressive anemia, but he wishes to call the attention of his colleagues to this aspect of the subject, and intends to study it further.

92. **Colon Bacillus.**—Four cases are reported by Bierring, presenting local peritonitis from gall-stones and gall-bladder

perforation, abscess of the liver, and septic appendicitis, in all of which were found pure cultures of the colon bacillus. Bierring concludes that this bacillus bears the same relation to the intestine that pyogenic cocci bear to the surface of the skin and the upper portion of the digestive and respiratory tracts. Each form, in its natural habitat, is harmless, their pathologic activities corrected by the physiologic resistance of tissue but when this is lessened they become capable of producing disastrous consequences.

93.—See abstract in The Journal of January 12, p. 126.

101. **Oxygen Treatment of Uricacidemia.**—After alluding to the former articles, in which he demonstrated the fact that uric acid is not the cause of uratic dyscrasia, etc., Croftan suggests that it will depend on the activity of the oxygenation processes whether uric acid, a non-toxic substance, is formed, or whether with deficient oxygenation, poisonous alloxuric bases are formed instead. The oxygenating processes in the human organism occur in two places, in the blood and in the periphery of all tissue cells. In one case oxygenation is derived from inspired air, and in order to cause oxygenation in the blood we can increase the proportion of oxygen in the air and promote its absorption, increase the quantity and activity of the red blood-corpuscles and the hemoglobin in the individual cells. To increase oxygenation at the cell periphery we can only act by raising the functional tone and the activity of all the organs. The author describes his method of giving oxygen inhalations, which he claims have the best results, educating as it were the perverted tissue-taint back to normal and possibly effecting a cure. Continued for a sufficient length of time an individual of ordinary chest capacity will get from ten to fifteen inhalations from the ordinary five-gallon bag, each treatment taking about five minutes. The diet is of importance, and in substance the same as that given in an abstract of his paper in last week's Journal, page 349. The drug treatment is essentially the same as that for secondary anemia: bichlorid of mercury in small doses, arsenious acid, and iron. High altitude is bad for these patients. That which is best is a dry, equable, semitropical, sea-level climate, or a very moderate elevation, with a large proportion of sunshine, such as is obtained in the Italian Riviera, Algiers, the Nile, and southern California.

102. **Uric Acid Diathesis.**—Tyson says the uric acid diathesis is remediable in two ways: 1. By eliminating the ingestion of nitrogenous food. 2. By increasing the quantity of water constituents of urine and by alkalinizing the blood and urine, favoring solution and elimination. Nitrogenous food should be limited. He sees no contraindication to the use of carbohydrates and hydrocarbons in these cases, provided they can be digested and assimilated and are not productive of acid fermentation. In addition to these foods there should be used, in reason, vegetables and diluent drinks to make up the dietary. He sees no objection to the use of fruits which are not too acid, such as oranges, grapes, peaches, pears, apples, etc., prohibiting acid fruits like strawberries, and especially if the fruit is difficult of digestion. Exercise, baths and massage should also form a part of the treatment. He also believes in the use of the alkalies, and uses chiefly the salicylates, citrates, and bicarbonates. His experience goes to show that the salicylates are the best. Piperazin has a disputed value, and while he does not speak of it strongly, from his own experience he has found it of value in the treatment of uric acid sediments. His point of view, as will be seen, is different from that of Croftan.

103. **Bathing in Typhoid Fever.**—Baruch offers the following method of home bathing in typhoid: Strip the patient and roll him upon his right side. The nurse, standing on the left of the bed, spreads a blanket over its left half and covers it with a linen sheet or old tablecloth. The patient is now rolled toward the left, upon his abdomen; the lower extremities are covered with a blanket. A basin of water at 80 degrees having been prepared, the nurse dips a rough wash-cloth into it, squeezes it lightly, and passes it, with some pressure, rapidly to and fro over the lumbar region. The cloth is again and again dipped and passed over the same part until it feels cool; other parts of the back, buttocks and thighs are similarly treated. Any water that may have flowed upon the blanket is now mopped up with a sponge. The whole back is now gently dried with a soft linen towel; the patient is turned over and the anterior part of the body is similarly treated. Chilling must be avoided by rapid using of good friction during the ablution; it will then not be necessary to apply it afterward. If the patient becomes chilly, the applications must cease, though this must not be taken as a demand for warmer water, but as an indication that too much water was used or it was applied too long. In two or three hours, if the temperature has reached 102.5 F., the ablution must be repeated with water 5 degrees colder, and applied with more friction. Thus the water temperature may be gradually reduced with advantage to 60 F. After the patient has been dried and had his gown replaced, a wet compress is applied over the abdomen, as follows: Cut three folds of old coarse linen to fit the anterior part of the body from the ensiform cartillage to the pubis, and lap over well on each side. Wring this out of water at 65 F., so that just enough water remains to saturate the cloth without its dripping. A piece of flannel large enough to pass entirely around the trunk and an inch wider than the linen compress is rolled into a bandage and spread beneath the body. The gown is rolled up under the arms, the wet compress is now applied over the abdomen, and the flannel bag snugly secured over it with three pins. The comfort of the patient and the good effect of the procedure depend on exact technique. The compress is continued hourly until the temperature reaches 100. When it rises to 103, or evidences of nerve depression become more pronounced, some stimulating procedure is required. The towel bath is an excellent measure. It is given by putting a dripping towel on the back, the patient lying on his abdomen, and water at 85 degrees dipped up and poured on the upper part of the back. The part is then rubbed by passing the flat hand rapidly over it until it warms, and another cupful is poured on and friction repeated. This is done three times unless the part fails to warm up. The process is carried successively over the entire back, buttocks and thighs, and they are then gently dried. The precautions to act quickly and stop when the patient's teeth chatter or evidence of chilling occurs must be remembered. If the febrile manifestations do not abate, the water temperature may be lowered five degrees each time until the towel water reaches 60 and the cup water 50 degrees. This last temperature will hardly be required unless stupor, delirium, or subsultus are persistent. In the sheet-bath, the entire body is wrapped in a linen sheet taken dripping out of water at 85 F. Colder water is poured from a cup, followed by friction as in the towel-bath. The ice rub is another energetic procedure. Instead of pouring cold water the patient is vigorously rubbed with cold pieces of ice held securely within a piece of white linen. Each part is thoroughly rubbed afterward with the flat hand, until it thoroughly warms up. Internally, four to six ounces of water at 40 F. should be given regularly every two hours, alternating with the same quantity of milk or other liquid food. The systematic drinking of cold water is an essential element in the hydrotherapy of typhoid fever.

112.—See abstract in The Journal of January 19, p. 205.

113. **Quinin in Labor.**—Fussell finds that the administration of quinin is a valuable stimulant in cases of uterine inertia, especially in cases of multiparæ. He thinks its employment will frequently obviate the use of forceps. He gives about 15 or 16 gr. at a dose.

114. See abstract in The Journal, xxxv, p. 1361.

FOREIGN.

The Lancet, January 19.

Some Cases of Head-Injury, Including One in Which There Was Lesion of the Occipital Bone. Herbert W. Page.—The author details several cases of injuries to the head which present certain points of interest, more especially the visual symptoms in one case which showed hemianopsia with irregularity of the field, following an injury to the occip bone with depression and removal of portions of the brain. The other cases were more ordinary. He particularly notices the occurrence of unconsciousness, especially when prolonged, and does not hold that it is in itself an evil omen. He quotes Sir James Paget, who said, in a verbal communication, that all things being equal, a certain amount of unconsciousness by giving rest to the shaken brain, aids sometimes to recovery, the condition of unconsciousness to the patient acting to some extent as the splint to an injured limb. Page remarks that he has taken something of the same view of the case himself, and does not consider that those in whom the loss of consciousness has been most prolonged are necessarily those in whom the prognosis is the most serious.

Ten Successful Cases of Cesarean Section. W. J. Sinclair.—The author gives detailed accounts of ten cases of Cesarean section, with general remarks on the subject. The time of the operation is a matter in which there is a great difference of opinion, but, as he says, in the majority of cases there is very little choice. We do not now, as in former days, use it as a last resort. In all cases incision of the uterus was postponed until it could be drawn forward out of the abdominal wound, and it is always best to insert an elastic tube so as to compress the uterine vessels in cases of emergency. It does not necessarily require any very large abdominal incision for, in the majority of cases, after rupture of the membranes, the volume of the uterus is not so great and the advantages of cleanliness and precision in the operation, by drawing up the uterus, are beyond question. The objection to elastic ligation has no basis. If the deep sutures are inserted as quickly as possible, tied tightly and the tube relaxed, hemorrhage is slight and the organ gradually assumes its natural color. If by the time the sutures are inserted and tied it looks bulky, it can usually be made to contract by manipulation, not directly with the hands, but through a suitable cloth. The size of the incision into the uterus should be sufficient to permit rapid extraction of the fetus without further laceration, and a one-half inch incision is a small matter as compared to the accident of tearing the uterine substance. Sinclair rejects the German method of incising the fundus, which he thinks in any case should be left free. When it is made in the most obvious position, the middle third in front and in the median line, it sinks down and comes in contact and adheres to the abdominal wound. A month or six weeks later the uterus is found exactly where it would be after a successful ventrofixation operation. Symphysiotomy, he believes, is dying out and getting to be obsolete, which he thinks is the better for humanity. As regards premature labor, it would be just as well to perform craniotomy as to wait until the twenty-eighth or thirtieth week when a viable child can not pass. If we look at the indications for Cesarean section, and compare them with those for the induction of premature labor, one can not fail to be impressed with the shortening of the one and the extension of the other.

Medical Press and Circular (London), December 19, 1900.

Extirpation of the Gasserian Ganglion.—Prof. Julius Dollinger reports his experience with the Hartley-Krause operation. The point especially made by him is the avoidance of the middle meningeal artery. By examining a large number of skulls he concludes that in 59 per cent. of the cases the place of entrance of the middle meningeal artery lies so far behind the foramen ovale that one can approach it without requiring the ligature and subsequent division of the artery. In 35 per cent. we can also remove the ganglion without ligating the artery, but to do so we must get at the ganglion, going behind in a median direction. The second root leaves the skull further forward; it is therefore accessible without ligature of the artery. He also concludes that in about 96 per cent. of cases the Gasserian ganglion can be removed without ligating and injuring the arteries, and he has thus performed the operation in five cases. The method employed is given as follows: "After opening the skull and bending back the bone flap, I introduce a finger between the dura mater and the base of the skull until I reach the middle meningeal artery. Before this I turned to the second and third division of the trigeminus and peeled off the dura mater with an elevator with a blunt point. On the way I introduced the elevator from outward and medianward to upward and backward. I could separate the Gasserian ganglion very easily, partly from the base of the skull and partly from the dura. In the same direction I reached the ganglion with forceps, and seizing it, I drew it out, together with the trigeminus root (having, of course, previously cut across the two divisions of the trigeminus mentioned above). I did not use the Krause spatula when lifting the brain, having only made use of this spatula in the first two cases performed according to the old method. Now I avoid its use, because the assistant who holds it can not see into the aperture leading to the base of the skull, and therefore he lifts the brain either too high or too low, to avoid which I have continually to guide his hand. For that reason I lift the brain myself with an elevator which is 1½ cm. wide, and is slightly bent on its flat side; I hold this in the left hand in such a way that I can perform the operation by the aid of light projected by an electric reflector." Following this plan considerably shortens the operation. The second operation which he performed lasted only twenty minutes and the average duration of the other three was thirty-eight minutes. The conclusions which he gives from a summing up of his experience are: "1. The Gasserian ganglion can be extirpated without ligature of the middle meningeal artery. This is proved by my five cases. The operation is thereby much shortened, and the complications arising from the ligature are obviated. 2. The anterior division of the artery in half the cases lies in the closed canal of the parietal bone more frequently than in the open sinus, but even then hemorrhage does not in every case occur on turning down the bone flap. 3. With regard to these rare cases of bleeding, we need not previously cut down on the external carotid artery, because, should hemorrhage occur while compressing the common carotid artery we have plenty of time to plug the foramen spinosum, or, when necessary, to ligature the external carotid artery."

Archives Gen. de Med. (Paris), October, November and December, 1900.

Endocranial Complications of Sphenoidal Sinusitis. Toubert.—The sphenoidal sinus is more frequently involved in case of nasopharyngeal infections than is generally appreciated, especially in the course of la grippe, pneumonia, erysipelas and typhoid fever. The sinusitis may then become complicated by fatal meningitis or phlebitis, and it is probable that a certain number of instances of meningitis, supposed to be spontaneous, are probably in fact complications of an ignored sinusitis. Diagnosis of sphenoidal sinusitis is very difficult on account of the variability and lack of precision of the symptoms, both subjective and objective. Exploration of the cavity of the sinus with a catheter or by puncture seems the best means of diagnosis. The endocranial complications are readily diagnosed, but they do not indicate the source whence infection was derived. Jacob's method of inserting the catheter is simple, the point is guided by the bones, after entering the nostril, following the natural curve formed by the deep surface of the bones of the nose, the cribriform plate of the ethmoid and the anterior surface of the sphenoid—the vault of the nasal fossa. When the convex side of the catheter strikes the posterior angle of the vault at the spheno-ethmoidal articulation, if the catheter is twisted slightly outward, it can be easily pushed into the sinus.

Sensory Disturbances with Cerebral Lesions. H. Verger.—More than 140 pages are devoted to the study of the general disturbances in sensibility consecutive to lesions of the cerebral hemispheres in man. Verger's conclusions are that general sensibility is not localized exclusively in the cortex. The terminal ramifications of the nerve-cells establish multiple relations between the inferior and cortical centers, which render possible new associations and the re-education of the cells. Twenty-four cases are described in detail, showing this substitution.

Pathogenesis of Cirrhosis of Liver with Cardiac Insufficiency. Piery.—The influence of stasis in the production of sclerosis of the liver has been investigated by Piery on twenty-four patients, with post-mortem and microscopic findings and experimental researches. He states that he has established that sclerosis of the liver, in case of weakness of the heart, is not a direct consequence of the stasis, and also that the latter alone is unable to produce sclerosis of the liver. The stasis, however, acts as a predisposing cause by the dilatation of the vessels and atrophy of the trabeculæ which it induces. This offers a favorable soil for the development of intoxications, especially alcoholism, and infections, such as tuberculosis and rheumatism. The resulting inflammation is the direct cause of the sclerosis. He describes his cases in full, 15 of what he calls "cardiac cirrhosis," and 9 of protracted asystolia with no sclerosis of the liver.

Bulletin Medical (Paris), January 5.

Simple Test of Isotonicity of Cerebrospinal Fluid. L. Bard.—Cryoscopy and other means of determining the isotonicity of the cerebrospinal fluid are, comparatively speaking, difficult and tedious measures. Bard finds that the same purpose is accomplished by mixing one drop each of the fluid and the blood of the subject. If the cerebrospinal fluid is hypertonic the red corpuscles remain intact, without even sticking together in rolls. The mixture looks like a combination of ordinary blood and artificial serum. If the cerebrospinal fluid is hypotonic, the blood mixed with it changes its character at once, the color becomes a uniform bright red and the microscope shows that the red corpuscles are dissolved.

Revue de Gynecologie (Paris), December.

Results of Surgical Treatment of Carcinoma of the Ovaries. E. Estor and P. Puech.—The mortality in 372 collected cases of cancer of the ovary was 26 per cent. from 1880 till 1890, and 21 per cent. during the last ten years; 265 were cured and 107 died, two-thirds from hemorrhage or shock. The general mortality in case of sarcoma and endothelioma was 17.3 per cent.; from carcinoma, 25.9 per cent., and from teratoma 15 per cent.; in those not confirmed by the microscope: sarcoma, 26.3 per cent., and carcinoma, 40.6 per cent. The deaths from carcinoma of the ovary are 8.1 times greater than those from sarcoma. The cases in which there were many adhesions had a mortality of 34.4 per cent.; carcinoma was complicated in this way in 76 per cent., and sarcoma in 66 per cent. When the operation required the sacrifice of some portion of an adjoining organ, the mortality was as follows: Uterus 1 in 8, intestines 3 in 4, and omentum 1 in 4. The cases show that recovery is possible at any age. Among the patients cured was a child of 20 months, and a woman of 67. The remote results of the operation were observed in 176 cases. Recurrence occurred in 59 per cent. In 40 patients, within three months; in 36, in less than a year; in 11, between 1 and three years; in 4, over 3 years, and in 4 the date was unknown. Of the 72 patients without recurrence, 28 were followed for more than 3 years; 16 between 1 and 3 years; 22 between 3 and 12 months, and 6 less than 3 months. This gives a proportion of 15 per cent. who have survived more than three years without recurrence. Among these 1 patient has been observed for 17 years, 1 for 16, 2 for 15, 4 for 12, 2 for 11, 1 for 9, 2 for 8, 2 for 7, 2 for 6, and 1 for 5 years. All those observed for more than eleven years were cases of sarcoma. Of the 54 with carcinoma confirmed by the microscope, recurrence occurred in 22, or 40 per cent.; in 111 cases of sarcoma, in 20, or 18 per cent., and in 6 cases of teratoma in 4, or 66 per cent. In 128 neoplasms not examined microscopically, recurrence was noted in 43, or 33 per cent. of those clinically diagnosed as carcinoma, and in 15 or 20 per cent. of 72 diagnosed as sarcomata. The proportion of cases of recurrence of carcinoma in the 89 cases followed was 73 per cent.; in the 83 cases of sarcomata, it was 32, or 42 per cent., and in the 4 of teratoma, 100 per cent. The tables show that early recurrence was more frequent with sarcoma than with carcinoma. No sarcoma recurred after three years had elapsed, while in carcinoma this happened in 4 cases. The report also emphasizes the greater frequency of survival without recurrence in sarcoma. Ricard gives the mortality after abdominal hysterectomy for carcinoma of the uterus as 23 per cent., and Delagenière as 15 per cent. The general mortality after operation for cancer of the ovary was only 21.3 per cent. in the cases collected above.

Drainage of Uterus in Treatment of Salpingitis. M. Beaussenat.—Walton's method of forcible dilation of the uterus, followed by curetting and prolonged drainage with a stiff rubber tube, has been applied by the writer in twenty cases of salpingitis consecutive to endometritis. The catarrhal form was always cured. This result was also frequently obtained in non-cystic, purulent salpingitis. Old and painful parenchymatous salpingitis was much improved in nearly every case. Peri-uterine infiltration may be absorbed after dilation, curetting and drainage of the uterus. The same treatment is also indicated for pyosalpinx if it is unilateral, recent, small, and has not caused many inflammatory symptoms, especially if operated on in the intervals between attacks of inflammation. The drainage is kept up from 10 to 22 days, changing the tube every second day, when the uterine cavity is irrigated with sublimate solution, swabbed out with 33 per cent. creosoted glycerin, and the vagina loosely tamponned.

Semaine Medicale (Paris), January 9.

Yeast in the Alimentary Canal. P. Nobecourt.—Brewer's yeast is being used in the treatment of furunculosis and other affections, but its action on microbes has never been thoroughly studied. Nobécourt has instituted researches in this line and finds that yeast fungi are extremely resistant to the factors to which they are exposed in the alimentary canal. The gastric juice alone is able to kill them after several hours' contact. They require a fermentable substance for a culture-medium in the alimentary canal. The possibility of the fermentation of glucose in this canal under the influence of yeast was also established. The vitality of the fungi was not impaired by contact with microbes, but the latter were affected by the fungi. The bacillus coli, proteus, pyocyaneus, typhoid and cholera vibrio, cultivated with the fungi, developed normally in contact with them, but when the fungus cultures were from two to six days old, these microbes grew very little or not at all. After this age, the cultures did not inhibit the growth of the micro-organisms. The effects in all cases varied slightly with the special fungus. Brewer's yeast diminishes the vitality of the typhoid bacillus. As the yeast fungi grow they impart acidity to the medium and maintain this acidity like a vital process. It may be directly injurious under certain conditions, and cases are cited where this acidity or the presence of fungi was a factor in the pathogenesis of certain affections of the alimentary canal, but he considers these exceptional cases, which should not prevent the therapeutic application of yeast. There is still much to be done, however, in establishing the indications.

Potassium Iodid Injection in Treatment of Eclampsia.—Bolle.—The disease analogous to puerperal eclampsia, which affects cows, is frequently fatal. A Danish veterinarian conceived the idea that the affection was due to toxins generated in the milk, and treated it by injecting potassium iodid into the mammary glands. Of 412 cows thus treated, 90 per cent. recovered, while the mortality had previously ranged from 40 to 66 per cent. Bolle has applied the same treatment to 15 patients with puerperal eclampsia, injecting 5 to 6 gm. of potassium iodid into the mamma or vicinity. All recovered except one in whom the treatment was not commenced until after the fifth paroxysm, with pronounced icterus and paralysis. The effect of the iodid is not evident for six hours, consequently it should be applied at an early stage, and possibly as a harmless preventive measure at the first suggestion of eclamptic symptoms.

Improvement in Celluloid Casts. Hersing.—When celluloid is softened in acetone, as usual, it requires several hours to harden. Hersing has discovered that if the strips of celluloid are dipped in hot alcohol they become so soft in two or three minutes that they can be applied at once, while in fifteen minutes they are as stiff again as before they were immersed in the alcohol. He uses strips of celluloid 5mm. thick and nearly four feet long by several inches wide for immobilization of cases of hip joint disease. The cast is so elastic that it can be removed and replaced intact.

Allg. Med. Cent. Ztg. (Berlin), December 22.

Bone Necrosis in Rubber Factories. Lazarus.—Twenty young women employed in the manufacture of rubber goods, exhibited a necrotic process in the jaws and teeth, similar to that observed in match factories. Lazarus calls this condition "rubber necrosis."

Berliner Klin. Wochenschrift, December 31.

Experimental Alopecia from Thallium Acetate. A. Buschke.—It has been noticed that the administration of thallium acetate to consumptives for night-sweats, has caused the hair to fall out. Buschke has confirmed this curious property of this substance by experiments on animals. The hair dropped off in patches or generally. He considers this phenomenon due to a neurotrophic influence of the drug, which also explains its action on night-sweats.

A Vascular Spinal Affection. F. Brasch.—In a severe case of nervous spinal disease which terminated fatally in two years, the causal lesion proved to be a dilatation, lengthening and winding course of a trunk vessel in the spinal cord, below the roots of the fifth dorsal nerve. It divided in the lumbar region, pursued a tortuous course, and was so enormously dilated that it assumed an aneurysmatic character. Hypertrophy of the heart was probably the primary factor.

Deutsche Med. Wochenschrift (Leipsic), January 17.

Vaginal Route in Operating for Tubercular Peritonitis. G. Baumgart.—The details of the 36 cases mentioned in the preceding issue are published in this communication. Of the 24 operated on more than two years ago, 17 were treated by abdominal section, with 64.7 per cent. complete recovery; 5.8 per cent. improvement and 29.4 per cent. mortality. The percentage of recoveries and improvements was practically the same in the seven cases in which the peritoneal cavity was entered through the posterior vaginal fornix, and Baumgart urges the superior advantages of the latter procedure in the treatment of tubercular peritonitis. He calls attention to the important information to be derived from rectal palpation, not only for diagnosis, but in the supervision of the process of recovery.

Tests of Renal Function. L. Lipman-Wulf.—The methylene blue test of the function of the kidneys produced widely different results in the experimental researches here reported. The only point that seems to be definitely established by them is that the stain is excreted through the epithelium of the convoluted tubules and Henle's loops, before it reaches the urine proper. None was ever found in the Malpighian corpuscles.

New Sensitive Test for Sugar. E. Rieger.—One gram of pure white phenyl-hydrazin hydrochlorate is placed in a shallow porcelain dish about 3 cm. in diameter. To this 5 gm. of sodium acetate are added and 1 c.c. of the sugar solution or urine. The dish is held over a spirit lamp until the contents are dissolved and begin to boil. It is then replaced on the table and 20 to 30 drops of a 10 per cent. solution of soda are added without moving the dish. The fluid turns a reddish-violet if there is sugar present, if there is no sugar the fluid merely shows a pinkish tint in the course of fifteen to thirty minutes. The red-violet stain must appear in less than a minute to denote a pathologic amount of sugar. The only precaution to be taken is to see that no other aldehyds are present, as they produce the same reaction as sugar.

Therapie der Gegenwart (Berlin), January.

Quinin Treatment of Typhoid Fever. W. Erb.—Quinin proved ineffectual in only one-seventh of the 200 cases of typhoid fever treated by Erb during the last ten years. In all the rest he was impressed with its favorable action, not merely as an antipyretic but in shortening the disease and modifying its manifestations. He commences to give it about the eleventh day, at 7 or 8 p. m., after the maximum temperature has been reached, administering 1 to 1.5 gm.—very rarely 2 gm.—in two doses close together. He continues it every second day thereafter until defervescence. The cases that resisted were all extremely severe, with complications.

Alcohol in Infectious Diseases. C. Fraenkel.—In a series of experiments on dogs, guinea-pigs, hens, pigeons, etc., conducted by Laitinen, under Fraenkel's directions, it was found that alcohol increased the susceptibility of these animals to infections and toxins. Fraenkel reviews his work and concludes that the administration of alcohol in infectious diseases is, to say the least, not an insignificant matter.

Treatment of Leg Ulcers. C. L. Schleich.—Peptone has completely banished plaster at Schleich's clinic for all cases in which a compressing and immobilizing bandage is required. It requires no padding beneath, can be worn for weeks or months, and, in its adhesiveness, porosity and solubility, surpasses all other substances known to date. He has found it peculiarly adapted to ulcers of the leg, and recommends it as satisfactory in every respect. After cleaning the ulcer, the leg is smeared thick with the peptone paste and cambric bandages applied, winding from the toes upward to the knee, with a starch bandage outside. The paste cools so slowly that it adjusts itself to the surface, and he has never noted any interference with the circulation. The bandage is changed in five or six days.

Wiener Med. Wochenschrift, December 22.

Prevention of Otitis After Measles. S. Weiss.—During a recent extensive epidemic of measles, the number of cases complicated by otitis was reduced from 27.7 to 6.6 per cent. by measures adapted to remove the accumulations of mucus from the nose and to keep the nasal passage clear. The nose was swabbed back to the posterior wall of the pharynx with a 1 per cent. salve of yellow precipitate, or the nostrils were plugged with cotton moistened with a few drops of a 5 per cent. solution of silver nitrate, the patient lying on his back and squeezing the nostrils together for a few moments. This application was repeated four times a day.

Gazetta Degli Osp. (Milan), December 2, 16.

Surgery of the Brain. Durante.—One of the two operations to remove a tumor on the brain was unsuccessful—no improvement was evident and the patient, a young man, died in coma four months after a second operation. The influence of a tumor in the anterior frontal lobe, in altering the moral character, was very marked in this case. The other patient was a child of 18 months and the tumor, located in the post-Rolandic zone by the symptoms, was found and successfully removed. He is now in perfect health. The tumor was a dural fibrosarcoma. Roncati found blastomycetes in it, as had been observed by other authors in malignant tumors. The fact that blastomycetes can not be isolated and cultivated from them is not surprising, as when they assume the form known as Russell's corpuscles, no cultures can be derived. Blastomycetes will always be found in malignant tumors, Durante asserts, if they are sought for with skill and patience. The coccidii that have been found are in reality blastomycetes, and the latter are the actual etiologic factors of sarcoma and epithelioma.

Spinal Analgesia. Bastianelli.—In 36 operations with the aid of spinal cocainization the analgesia was incomplete or entirely absent in 12. The dose was 1 c.c. of a 1 per cent. solution of cocain. In one case there was serious collapse, and in another violent headache for a week. There was more or less intense and protracted headache lasting for variable periods in every case.

Preservation of the Ovaries After Hysterectomy for Myofibromata of the Uterus. Pascale.—For three years Pascale has been making a special clinical and experimental study of the changes in the ovaries after complete ablation of the uterus for myofibroma. He invariably noted disturbances in the circulation, mostly mechanical, evidences of degeneration and processes of atrophy—a premature senility, which gradually overwhelmed the organ. The degeneration proceeds most rapidly in the parenchyma, while the epithelium does not degenerate with it at first, and this loss of balance between the two parts is probably the reason for the alteration of the ovary, in which it gradually loses its specific characteristics and its functionating power.

Action of Iodin in Tubercular Peritonitis. Biagi.—Six cases of tubercular peritonitis are reported; all were cured by local injections of 1 to 3 cgm. of iodin a day. The absorption of the fluid was very slow. Ninety-three injections were necessary in one case. The iodin was given in Durante's iodin iodid mixture. This communication was presented at the Italian Congress of Surgery two months ago, and others confirmed the results obtained with it and with Sclavo's iodized milk. It is possible to inject as much as 25 cgm. a day of the latter without pain. In some of the cases the cure has lasted for five years. The iodin is not a specific. but merely assists the organism to increase its powers of resistance.

Experimental Infection in Fasting Animals and Serotherapy. G. CASTRONUOVO.—Experiments on animals at the Naples clinic, in charge of De Renzi and Pane, show that fasting may hasten the fatal termination of infections. Specific serotherapy in experimental pneumonia is unable to save the animal when the infection is *too far advanced*, but in an early stage it is invariably checked and the animal recovers. Antidiphtheria serum, mixed with diphtheria *toxin in* such amounts as to neutralize a given quantity in the organism, is unable to produce this neutralization in fasting rabbits and death occurs.

Queries and Minor Notes.

PHOTOMICROGRAPHS.

OMAHA, NEB., Jan. 29, 1901.

To the Editor:—I write to obtain information relative to the making of some micro-photographs. The sections, from a tumor, are stained and mounted. I would like to have a number of negatives taken from which to select the ones I desire: I wish to have four and possibly five. Should I decide to have these micro-photographs colored can you tell me the probable cost and where I can have this work done in the most satisfactory manner? Very truly yours, J. E. S.

ANS.—In the first place, the term microphotograph is incorrect. Photomicrograph is what the writer evidently means, as microphotograph has a quite different signification. In all probability there are in every large city men who can do the work required above, but the only one we are at present able to refer the enquirer to, is Dr. W. H. Knap, 603 Stewart Bldg., Chicago. The coloring can be done by hand only. A rough sketch of the field desired should accompany the *slides; the particular tissue or* cells that the sender wishes brought out most clearly in photograph should be indicated.

PRACTICE IN OKLAHOMA.

BLUE HILL, NEB., Jan. 25, 1901.

To the Editor:—What is the law governing the practice of medicine in Oklahoma Territory? W. C. F.

ANS.—Oklahoma requires that the applicant shall be a graduate of a reputable medical college, of good moral character, and not a habitual drunkard. Presentation of diploma or proof by affidavit, if the same is lost or destroyed, and an affidavit from two reputable citizens in the county where he resides that he possesses the qualifications of a physician, to the *superintendent of the public* health, will obtain a license; otherwise an examination will be required.

ODOR OF MORPHIN.

KANSAS CITY, MO., Jan. 27, 1901.

To the Editor:—Does morphin impart to the breath of one addicted to the use of it, an odor by which it may be recognized? If so, what is it? Will you kindly give briefly the *etiology, pathology*, symptoms and treatment of strokers' cramps? G. B. T.

ANS.—Referred to our readers.—[Ed.]

TUBERCULOSIS TRANSACTIONS.

INDIANAPOLIS, IND., Jan. 28, 1901.

To the Editor:—Where and at what cost can the transactions of the last Congress of Tuberculosis (Germany) be secured? L. B.

ANS.—The Transactions of the Berlin Congress of Tuberculosis are not published in this country, and the bulk of the papers are in German or French. A copy can be obtained through any importing bookseller at a cost of between $3 and $4.

Change of Address.

The Public Service.

Army Changes.

Movements of Army Medical Officers under orders from the Adjutant-General's Office, Washington, D. C., *Jan. 17 to 23*, 1901, inclusive:

Harry D. Belt, acting asst.-surgeon, former orders directing him *to proceed to Manila on the transport Wright*, revoked; leave of absence granted.

William C. Borden, captain and asst.-surgeon, U. S. A., member *of a board at Washington Barracks, D. C., to examine officers of* the army for promotion.

Lawrence C. Carr, major and surgeon, Vols., on expiry of present leave of absence to proceed to Havana, Cuba, for duty in the Department of Cuba.

Frederick W. Coon, acting asst.-surgeon, relieved from duty in the *Department of Cuba; to proceed to San Francisco, Cal.*, for duty with troops en route to Manila, P. I., and subsequent assignment in the Division of the Philippines.

A. E. Disney, *acting asst.-surgeon*, from Washington, D. C., to San Francisco, Cal., for temporary duty at the general hospital, Presidio of San Francisco.

Herbert I. Harris, *acting asst.-surgeon*, member of a promotion board at St. Paul, Minn., vice Lieut.-Col. Calvin DeWitt, relieved from duty on the board.

William M. Hendrickson, *acting asst.-surgeon*, from Fort Flagler, to duty at Fort Casey, Wash.

John Van R. Hoff, major and surgeon, U. S. A., member of a board at Washington, D. C., *to examine medical officers* for promotion.

THE JOURNAL OF THE
AMERICAN MEDICAL ASSOCIATION

61 Market Street : : Chicago, Ill.

Cable Address: "Medic, Chicago"

Subscription price: Five dollars per annum in advance

Postage in the United States and Canada, Mexico, Hawaii, Guam, Porto Rico, and the Philippines, free; foreign postage, $2.50. Subscriptions may commence at any time. Volumes begin with the first issue of January and of July.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

The qualifications for membership require that the applicant be a member, in good standing, of a state or local medical society entitled to send delegates to the annual meeting of the American Medical Association. A list of these societies will be sent on request. Applications must be accompanied with a certificate showing that the applicant is a member of a recognized society, and should be sent with the annual dues—five dollars—to the treasurer, Dr. Henry P. Newman, 100 Washington Street, Chicago. Members receive The Journal free. Subscribers to The Journal may become members of the Association without additional expense if they are members of medical societies recognized by the Association. Those desiring to have their names transferred from the subscription to the membership lists should send certificates as above, with a receipt for their subscription to The Journal, covering the current fiscal year.

FISCAL YEAR.

The fiscal year of the American Medical Association is from January 1 to December 31; and the annual dues paid by a new member cover only the fiscal year, no matter at what time of year the membership is obtained. Those who pay their dues and join the Association at the annual meeting in June, for instance, pay only for the fiscal year which ends with the December following, and the annual dues for the following fiscal year are payable the succeeding January, at which time the treasurer sends a statement to each member. Such members, however, are entitled to The Journal for the full year, even though the membership be not continued.

PAPERS READ AT THE ANNUAL MEETING.

"Every paper received by this Association and ordered to be published, and all plates or other means of illustration, shall be considered the exclusive property of the Association. . . The Board of Trustees shall have full discretionary power to omit from the published transactions, in part or in whole, any paper that may be referred to it by the Association or either of the Sections, unless specially instructed to the contrary by vote of the Association." (From Article V of the By-laws.)

NEWS.

Our readers are requested to send us items of news of a medical nature, also marked copies of local newspapers containing matters of interest to members of the medical profession. We shall be glad to know the name of the sender in every instance.

ORIGINAL PAPERS.

Articles are accepted for publication with the understanding that they are contributed solely to this journal.

COPYRIGHT.

Matter appearing in The Journal of the American Medical Association is covered by copyright, but as a general thing, no objection will be made to the reproduction of anything appearing in its columns if proper credit be given.

CONTRIBUTIONS TYPEWRITTEN.

It will be satisfactory to all concerned if authors will have their contributions typewritten before submitting them for publication. The expense is small to the author—the satisfaction is great to the editor and printer. We can not promise to return unused manuscript.

Half-tones, zinc etchings and other illustrations will be furnished by The Journal when photographs or drawings are supplied by the author.

ADVERTISEMENTS.

Advertising forms go to press eight days in advance of the date of issue. Therefore, in sending in copy, time should be allowed for setting up advertisements and for the sending and return of proofs. Advertising rates will be made known on request.

CHANGE OF ADDRESS.

In ordering a change of address it is important that both the old and new addresses be given.

REMITTANCES.

Remittances should be made by check, draft, registered letter, money or express order. Currency should not be sent, unless registered. Stamps in amounts under one dollar are acceptable. Make all checks, etc., payable to "Journal American Medical Association," except those for annual dues. These should be made payable and sent direct to the Treasurer, Dr. Henry P. Newman, 100 Washington Street, Chicago.
